Prof. Jean Politis directed attention to the part played by certain substances in the struggle of the plant against a parasite. He stressed the fact that the vacuoles containing such substances are derived from the cell nucleus, and are therefore under the same hereditary influences as the nucleus. The degree of hydration of the vacuole determines the susceptibility or resistance of the host, according to Prof. H. S. Reed, who also proceeded to review the influence of nutritive relations upon host-parasite reactions. Prof. A. J. Riker had a short but interesting paper on "Biochemical and Physical-Chemical Studies on the Bacteria which stimulate Atypical and Pathological Multiplication of Plant Cells".

---

*IIIme. Congrès Internat. de Path. Comparée, Athènes. Tome premier, Rapports, 2me Partie, Section de Path. Végétale, "L'Immunité Chez les Végétaux". (Athenes: Editions "Flamma", 1936.)

Much light can be thrown on the problem of immunity by a study of the resistance of plants to non-living poisons and alkalis. Dr. Winifred E. Brenchley considered the effect of excess mineral nutrients, of inorganic and organic poisons, of gases and sprays, and in the section on resistance to alkalis reviewed much recent work on the plants of chalky soil, and on chlorosis. Prof. F. T. Brooks discussed the resistance of trees to ligneous fungi, and Dr. Tewfik Fahmy described the production of cotton plants immune to the fungus ***Fusarium vasinfectum*** var. ***Egypticum***, by breeding and selection.

Prof. L. W. Rischkow reviewed the conditions where resistance of the host was shown towards virus diseases, and Dr. R. N. Salaman dealt with the same subject, but from a different point of view. He showed that a plant could be rendered immune from attack by a virulent form of virus 'X', if it were previously vaccinated with a non-virulent strain of the same virus. Dr. Kenneth Smith and Mr. J. P. Doncaster had a paper on "The Particle Size of Plant Viruses".

Immunity against bacterial plant pathogens was treated in an encyclopædic manner by Prof. Tr. Săvulescu, who claimed that the use of vaccines or bacteriophage, in plant therapy, is understood in theory, but is not yet of practical utility. A very extensive bibliography appears at the end of Prof. Săvulescu's paper. Two very informative papers on "The Nature of Resistance of Cereals to Rust", by Dr. E. C. Stakman and Miss Helen Hart, and "The Development of Disease-Resistant Plants", by Dr. H. B. Humphrey, end the volume.

The teacher of mycology, and those plant pathologists who were not fortunate enough to attend the Congress, cannot but be grateful for this volume of reports. It is a welcome gathering of knowledge from many, and often conflicting, points of view, which do not appear so conflicting when tempered by the international atmosphere of the conference, and when bound within the confines of one volume. With the exception of one paper in Italian, all the communications are in English, French or German, and with the provision of a French summary to each article, the contents will be available to most students.

Science News a Century Ago

Prof. Edward Turner (1798-1837)

On February 13, 1837, Prof. Edward Turner died at Hampstead at the age of thirty-nine years through inflammation of the lungs. He had been appointed professor of chemistry at University College, London, in 1828, and his death was regarded as a severe loss not only to the College, but also to many scientific societies in the Empire. Born in Jamaica in 1798, he was taken to Edinburgh at an early age and was educated there, graduating M.D. in 1819. After a period of study under Stromeyer at Göttingen, he began to lecture in Edinburgh and published his "Introduction to the Study and Laws of Chemical Combination", which he afterwards worked into his "Elements of Chemistry", 1827, one of the standard text-books of the time.

At University College, Turner had a large class and his lectures were remarkable for their lucidity. Speaking of his work to the Chemical Society in 1900, Sir Edward Thorpe said he was "an excellent manipulator and his analytical and determination work was of a high order. He is specially to be remembered for his determination of the atomic weights of lead, chlorine, silver, barium, mercury, nitrogen and sulphur; they were the first atomic weights to be measured by a British chemist and are worthy to be ranked with those of Berzelius". In the course of his work, Turner pointed out that the atomic weights hitherto commonly used by British chemists had been adopted without due inquiry and that several of the most important ones were erroneous, and that the hypothesis that all equivalents are multiples of a whole number of the equivalent of hydrogen was inconsistent with the state of chemical knowledge at the time, being at variance with experiment. His work led to the rejection of Prout's theory, and the position he arrived at was precisely that to which Stas arrived half a century later."

Turner was buried in Kensal Green Cemetery. A marble bust of him was placed in University College by his pupils. He was succeeded by Thomas Graham.

Claude-Pierre Molard (1758-1837)

By the death on February 13, 1837, of Claude-Pierre Molard, the French nation lost a distinguished mechanician who had been one of the most active founders of the National Conservatoire des Arts et Métiers in Paris and its director from 1801 until 1816. When he died, he was president of the Section of Mechanics of the Paris Academy of Sciences. Molard was the elder brother of another well-known mechanician, Emmanuel-François Molard (died 1829), and was born near St. Claude, Jura, on June 6, 1758. Though the son of poor parents he was able to attend schools at St. Claude and Lyons and became a draughtsman, his ability as such attracting the attention of Jacques de Vaucanson (1709-82), who had formed a collection of machines which he left to the nation, and which eventually formed the nucleus of the collections at the Conservatoire.

In 1785, Molard went to Paris to work under Vandermonde, who was in charge of Vaucanson's collections, and he was made a member of the commission appointed by a decree of February 11, 1794, to report on the preservation of monuments and works of art. To this commission belonged Lamarck, Berthollet, Vauquelin, Monge, Prony and other men of science, and it was through them the decree of 19 vendémiare an III. (October 10, 1794) was passed which led to the foundation of the Conservatoire.

Skey on Muscular Fibre

At a meeting of the Royal Society on February 16, 1837, a paper was read by Frederic Skey entitled "On the Elementary Structure of Muscular Fibre of Animal and Organic Life". The author, said the report, concludes from his microscopic examination of the structures of muscular fibres that those subservient to the functions of animal life have, in man, an average diameter of one 400th of an inch, and are surrounded by transverse circular striæ varying in thickness and in the number contained in a given space. Each of these muscular fibres is divisible into bands or fibrillæ, each of which again is subdivisible into about one hundred tubular filaments, arranged parallel to one another, in a longitudinal direction around the axis of the tubular fibre which they compose, and which contains in its centre a soluble gluten. The diameter of each filament is one 16,000th of an inch.

Frederic Carpenter Skey (1798–1872) was a pupil of Abernethy and became successively assistant-surgeon, lecturer on anatomy and surgeon at St. Bartholomew's Hospital. He was elected F.R.S. in 1837 and in 1863 served as president of the Royal College of Surgeons.

Royal College of Surgeons

THE *London Medical Gazette* of February 18 contains the following eulogy of the Royal College of Surgeons:

"Of the existing institutions connected with the medical profession the College of Surgeons is in various respects by far the most important. The building is worthy of the great national establishment; the library is a magnificent addition, which has grown up of late years; the museum is a monument worthy of the name it bears, and creditable to the nation. Nor do the names of many among its present members reflect less honour upon English surgery than the greatest of their predecessors, while of the existing Council it is but justice to add that they have shown their determination to keep pace with the march of intellect and the improvement of the times. In these respects—we mean setting aside ancient prejudices—in gathering wisdom from passing events—and in rendering their institution available to great national objects—we must say they have far outstript their elder brethren in Pall Mall, and accordingly are their character and influence as a public body proportionately greater. It is in Lincoln's Inn Fields that the battle between the new and the old race of practitioners must be fought. . . ."

University Events

CAMBRIDGE.—Prof. J. Proudman will give a course of six lectures on dynamical oceanography in the Zoological Lecture Theatre at 5 p.m. on Mondays, Wednesdays and Fridays, commencing on Monday, February 15.

The following have been approved for the degree of Sc.D.: D. A. Bannerman, of Pembroke College, and E A. Guggenheim, of Gonville and Caius College. Miss Frances Mary Hamer, of Girton College, has been approved for the title of the degree of Sc.D.

EDINBURGH.—The Cameron Prize for 1937 has been awarded by the Senatus to Prof. J. Bertram Collip, professor of biochemistry in McGill University, Montreal, in recognition of his many contributions to endocrine therapy and in particular his work on the parathyroid gland.

At a meeting of the University Court on January 25, an offer was received from the University Grants Committee of a non-recurrent capital grant up to a maximum of £15,000 towards the cost of a building for a Students' Union for men and women on the King's Building site at West Mains Road, the building to include a refectory and a gymnasium. The total cost, exclusive of furnishings, is estimated at £20,000, and the Committee has offered the grant on condition that the remainder of the cost be obtained from other sources, and that the scheme should be proceeded with as soon as possible, and in any case within two years from the date of the offer.

Societies and Academies

London

Royal Society, February 4.

R. A. WATSON WATT, A. F. WILKINS and E. G. BOWEN: The return of radio waves from the middle atmosphere. Observations spread over a year from May 1935 have established the existence of sustained stratified electrification, persisting for several days, of such ionization density and gradient as to return radio waves of frequency 6–12 Mc./sec. at vertical incidence, at such heights as 8·5, 9·3, 10·3, 10·75 and 13·5 km. with reflection coefficients of the order of 0·7, giving measurable echoes up to the tenth order, beyond which they are not readily distinguished from ionospheric echoes. Apparently independent stratification at 45–50 km., with a reflection coefficient of 0·3 for 6 Mc./sec. waves, and the *D* region at and above 60 km. are also recorded. Reflections from all these regions are obtained at and above the frequencies proposed for television services. The ionization does not fall to very low values at night, and has no seasonal variation of large amplitude. Evidence is given of replenishment around the 20–30 km. levels by local thunderstorms.

H. J. BHABHA and W. HEITLER: The passage of fast electrons and the theory of cosmic showers. Relativistic quantum mechanics have been used to calculate the number of secondary positive and negative electrons produced by a fast primary electron with energy E_0 passing through a layer of matter of thickness l. The primary electron in the field of a nucleus has a large probability of emitting a hard light quantum which creates a pair. The pair electrons emit again light quanta which create pairs, and so on. The number of secondaries increases rapidly with E_0. If an electron of 10^{11} e-volts passes through a lead plate of 5 cm. thickness the number of particles emerging from the plate amounts to 1,000 or more. Thus showers can be explained by the ordinary quantum theory. Comparison with experiments shows that Rossi's transition curve and Regener's absorption curve in the atmosphere can be understood on this theory. The penetrating power of fast electrons appears to be very much greater than a straightforward consideration of the energy loss would indicate. The absorption coefficient of the radiation found at a depth of 100 metres of water cannot, however, be understood on the basis of this theory if this radiation is due to primary electrons.

Paris

Academy of Sciences, January 11 (*C.R.*, 204, 77–160).

MARCEL GODCHOT and MLLE. GERMAINE CAUQUIL: The action of hydrocyanic acid on 4-methylcyclohexanone and the preparation of the two stereoisomeric 4-methylhexanol carboxylic acids.

PAUL LÉVY: The arithmetic of the laws of probability.

MARC COURTAND: *Gauche* curves of the third order.

PAUL VINCENSINI: Bodies of constant width in space of three dimensions.

ANDRÉ MARCHAUD: The contingent and paratingent at a point of a simple Jordan surface.

MICHEL GHERMANESCU: Homofocal quadrics.

LOUIS THIBAUDIER: The Poncelet polygons inscribed and circumscribed in two conics.

MAX EGER: The canonical systems of an algebraical variety.

DÉMÉTER MANGERON: Certain boundary problems for a class of partial differential equations of higher order.

NATAN ARONSZAJN and ALEXANDRE WEINSTEIN: The convergence of a variational method of approximation in the theory of encased plates.

ALEX GARDEDIEU: Heterogeneous fluid masses in rotation.

NICOLAS SLIOSKINE: The oscillations of rotation of an unlimited cylinder filled with a viscous liquid.

JACQUES VALENSI: Measurement of the circulation along various sections of a wing.

RENÉ SWYNGEDAUW: The position of the neutral line in homogeneous belts.

JEAN LAGRULA: Measurements of the intensity of gravity carried out in northern Africa during the year 1936.

MME. MARIE ANTOINETTE TONNELAT-BAUDOT: The linearization of the density of energy and of the action function with the assistance of complex vectors.

LOUIS LEPRINCE-RINGUET and JEAN CRUSSARD: Study of the particles of high energy in the cosmic radiation in the magnetic field of the Bellevue electromagnet. In this work a Wilson chamber was placed between the poles of the large electromagnet at Bellevue, giving a field of 13,000 gauss. About five hundred trajectories have been measured and an analysis of the results obtained is given.

MME. NELICIA MAYER: The oxido-reduction potential of reductinic acid.

ARAKEL TCHAKIRIAN: The electrolysis of germanochloroform or germanohydrochloric acid. The experimental results furnish a further proof of the existence of the complex ion $Ge^{+II}Cl^3$, in agreement with the theory of G. Urbain.

LOUIS BRÚNINGHAUS: A new fluorometer. A modification of the Gaviola instrument, the Kerr cells being replaced by piezoelectric quartz.

GEORGES ALBERT BOUTRY: A new type of photoemissive cell. Discussion of the causes of the errors of the usual type of photo-cell and suggestions for eliminating them.

MLLE. YVETTE CAUCHOIS: The L absorption spectrum, and the characteristic levels of mercury.

ALBERT PORTEVIN and LOUIS GUITTON: Contribution to the study of the role of inclusions in the corrosion of steels.

CHARLES DUFRAISSE and ROBERT PRIOU: Dissociable organic oxides. The photo-oxide of mesodimethoxyanthracene, $C_{16}H_{14}O_4$. Photo-oxydimethoxyanthracene was prepared and, contrary to the authors' expectation, was not dissociable.

RAYMOND QUELET and JEAN ALLARD: The synthetic preparation of ethoxy-methylbenzyl alcohols.

JULES JARROUSSE: Diphenylpyruvic acid. Preparation of the phenylbenzylsuccinic acids.

RENÉ JACQUEMAIN and ALFRED MOSKOVITS: Some compounds obtained with the aid of iodoargentonitrobenzoic complex compounds.

L. CAPDECOMME and G. JOURAVSKY: The indicators of reflective powers of slightly absorbent crystals.

GÉRARD WATERLOT: The structure of the Cambrian massif of Rocroi.

L. PETITJEAN: The comparative variation of the anomalies of barometric pressure and the solar activity. Over the interval 1884–92, the polar air was more active than the tropical air when the number of sunspots presented a more rapid diminution or a slower increase.

ALEXANDRE DAUVILLIER and ANATOLE ROGOZINSKI: The reality of Hoffmann shocks. From the experiments described, the authors conclude that the Hoffmann shocks do not represent a special accidental form of discharge in gases, but they measure effectively the energy of the particles associated with cosmic radiation.

RENÉ SOUÈGES: The embryogeny of the Primulaceæ. The development of the embryo in *Samolus Valerandi* (brook-weed).

JEAN LE CALVEZ: The schizogonic process in the foraminifer *Planorbulina mediterranensis*.

MAURICE ROSE and MLLE. M. HAMON: The dehiscence of some spermatophores of decapod crustaceans.

RAYMOND TURPIN and ALEXANDRE CARATZALI: The influence of twin births and of maternal age on the proportion of the sexes.

JACQUES RABATÉ: Gaultherioside (ethylprimeveroside). Its biological synthesis. In a previous communication, a new heteroside, gaultherioside, was described as obtained from the leaves of *Gaultheria procumbens* (winter-green). It is now found to be formed from primeverose and the alcohol used for the extraction, and probably does not exist in the leaves.

JEAN ROCHE and RENÉ COMBETTE: The osmotic pressure and molecular weight of various erythrocruorins (invertebrate hæmoglobins).

DENIS BACH: The destruction of the dehydrogenases of the yellow *Staphylococcus* by heat. The protective action of the substrate.

Moscow

Academy of Sciences (*C.R.*, 4, No. 3; 1936).

V. S. IGNATOVSKIJ: The Laplacian transformation (3).

S. LECHNICKIJ: The strains in an endless anisotropic plate weakened by an elliptical hole.

P. A. WALTHER: Pressure on wings, and its momentum at high velocities.

J. WEICHHERZ and B. GOUGUELL: A new equation expressing the state of matter.

M. B. NEUMANN and P. M. TUTAKIN: The transition of a cold flame into a hot one at low-temperature auto-ignition of butane.

V. ŠARONOV: Determination of the light-extinction factor and of the field of vision by the data obtained with an apparatus for measuring the haziness of air.

M. A. ROSENBERG, K. E. AVALIANI and F. B. JURKOVSKAJA: Dissolution of the 'vacuum films' of metals in acids. (1) Dissolution of chromium in sulphuric acid.

V. V. TIŠČENKO and M. D. RYDALEVSKAYA: An attempt at the chemical investigation of the humic acids of different soil types.

B. N. FORSCH: Geochemical composition of oceanic and of continental water (the water of Lake Baikal).

A. TARANETZ: Description of three new species of the genus *Icelus* Kroyer (Pisces, Cottidæ) from the Sea of Japan and from the Okhotsk Sea.

E. P. SLASTENENKO: Species of the genus *Tripterygion* found in the Black Sea (Pisces, Clinidæ).

G. Streich and E. Svetosarov: Significance of temperature and of the sexual hormone in the moulting process of birds.

E. Svetosarov and G. Streich: Factors determining the sexual and the seasonal dimorphism in ducks.

Erratum.—The title of the paper by S. Sobolev (Nature, Jan. 2, 1937, p. 40) should read: The fundamental boundary problem for polyharmonic equations in a domain with degenerated contour.

Prague

Czech Academy of Sciences and Arts, January 17, 1936.

Jar. Petrbok: Molluscs from the travertine of the Slovak karst formation, from Janovce and its neighbourhood, Spiš and Rušbach.

B. Němec, J. Babička, A. Oborský: Occurrence of gold in horse-tails. *Equisetum palustre* (having more than sixty per cent SiO_2 in the ash) accumulates gold from soil with 0·2 gm. gold per ton so that its ashes contain 610 gm. per ton. The soil consists of decomposed andesite and rhyolite.

J. Milbauer: The associated phenomena of catalysis. Pairs of catalysts like Pd, SeO_2, $HgSO_4$, Ag_2SO_4, $CuSO_4$ are much more efficient in the oxidation of carbon monoxide by hot concentrated sulphuric acid than single catalysts.

F. Valentin: On 3.6-anhydromannite.

March 20.

Z. Bažant: The precise solution of the walls of cylinders.

E. Votoček and S. Malachta: New transitions from the series of the sugars to those of the pyranes and pyrrols. Methyl-*iso*-pyromucic acid.

J. Komárek: Can the larvæ of food pests produce intestinal diseases?

J. H. Křepelka and V. Švarc: Contribution to the extraction and identification of veronal and luminal.

J. Bašta: Theory of the fatigue of materials, especially in engineering structures.

L. Borovanský: Sexual dimorphism of the human skull.

F. Němejc: Palæobotanical research on the travertine deposits of the Slovak karst.

V. H. Matula: The preparation of an accurate emanation standard from pitchblende. This is dissolved in hydrochloric acid, silica is separated and decomposed by hydrochloric acid; any residue is dissolved in nitric acid and added to the solution.

May 29.

J. Milbauer: (1) Study of carbonyl sulphide. This substance decomposes in concentrated sulphuric acid already at 150° C. In the presence of palladium as catalyst, it reacts at 90° C.; other catalysts show decreasing effects in the series SeO_2, Pt, Ag_2SO_4, $CuSO_4$, V_2O_5, $HgSO_4$, TeO_2, SnO_2, Sb_2O_3. (2) Remarks on the author's work on catalysts.

K. Kavina: Allogony of *Salix caprea* L.

V. Janda: Colour change of transplanted skin, and artificially united body fragments of *Dixippus morosus*.

R. Brdička: Dependence of the polarographic reaction of proteins on hydrogen ion concentration. The catalytic polarographic protein reaction giving a characteristic 'wave' on current-voltage curves is shown not only in the presence of ammonium chloride and ammonia, but also in any buffered solution. The 'wave' depends on the concentration of protein, on the hydrogen ion concentration of the solution, and on the quality and capacity of the buffer.

F. Němejc: Contribution to the recognition of Permo-Carboniferous flora in the coal deposits of the foot of the north-east slope of Velebit (Jugoslavia).

A. Vančura and V. Sutnar: The chronological development and pathogenesis of the syndromes inside and exterior to the kidneys in acute nephritis following angina.

B. Bouček: Graptolites of the Bohemian lower Ludlow.

A. Říha: The new bellerophontids of the Czech Palæozoic.

October 23.

B. Němec, J. Babička and A. Oborský: New analysis of plant ashes from auriferous ground. The content of gold found in the ashes of plants is in *Equisetum arvense* 576, *Mentha arvensis* 300, *Clematis vitalba* 110 gm. per ton. In *Fagus sylvatica*, *Carpinus Betulus*, *Salix caprea*, *Polyporus fomentarius* only traces. In seeds more gold than in wood; the gold content increases with the silica content.

E. Votoček and Z. Allan: The rotation of certain sugar hydrazones with respect to the α-configuration of carbon.

E. Votoček and J. Wichterle: The connexion between the rotation of sugar hydrazones and the α-configuration of carbon.

E. Votoček, F. Valentin and J. Bulíř: The constituents of mullein-seed oil.

J. Milbauer: The minimum quantities of catalysts having maximum effect in concentrated sulphuric acid. In the oxidation of gases by concentrated sulphuric acid at 250° C., homogeneous catalysts (like copper, mercury and silver sulphates) give a maximum effect when their solubility is reached. Heterogeneous catalysts (like the platinum metals) act most through their dissolved portion. Ruthenium, rhodium and palladium are more efficient than osmium, iridium and platinum.

V. Hlavatý: The system of Weyl connexions.

J. Bašta: Preliminary contribution to the mechanical theory of the equation of state.

P. Pachner: Sexual dimorphism of the human pelvis, and mutual relations of pelvic measurements.

V. Hovorka: Separation of lead from sulphuric acid, and determination of lead by means of *o*-hydroxyquinoline.

O. Pankraz: Two integral equations.

Vrat. Velich: Agar and saponin from malt as a preferential culture base for mycoderms.

V. Kryštofek: The problem of simultaneity and the theory of relativity.

November 27.

B. Bouček: Silurian stratigraphy in the Daleje valley.

F. Němejc: (1) The seed cones of *Discinites* K.F. (2) A revision of the Carboniferous and Permian flora of the Central Bohemian coal basin.

O. Pankraz: A special condition for the stationary circulation of economic goods.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, February 15

Royal College of Surgeons of England, at 4.—Prof. G. E. Gask: "John Hunter in the Campaign in Portugal, 1762–1763".

Royal Geographical Society, at 5.—H. P. Smolka: "The Economic Development of the Soviet Arctic".

Imperial College—Royal College of Science, London, at 5.30.—Prof. W. L. Bragg, F.R.S: "The Structure of Alloys".*

Tuesday, February 16

Institution of Civil Engineers, at 6.—Sir Noel Ashbridge: "Modern Developments in Broadcasting Radio Transmission and Television".

Wednesday, February 17

Royal Meteorological Society, at 5.—Dr. C. E. P. Brooks: "Meteorological Circumstances of the Floods in the United States of America".

University of London Institute of Education, at 5.30.—Dr. W. G. Adams: "Adult Education in England" (John Adams Lecture).*

Institute of Chemistry (London and South Eastern Counties Section), at 7.30.—Prof. J. F. Thorpe, F.R.S: "The Past and Future of the Institute".

Royal Society of Arts, at 8.15.—Dr. R C. Fisher: "Recent Work on Wood-destroying Insects".

Thursday, February 18

London Mathematical Society, at 5—(in the rooms of the Royal Astronomical Society, Burlington House, W.1). Prof. G. H. Hardy, F.R.S.: "Ramanujan and the Theory of Primes".

Friday, February 19

Geological Society of London, at 3. Annual General Meeting.

International Society of Leather Trades' Chemists, February 19–20. A symposium on "Scientific and Technical Aspects of Wetting and Detergency" to be held in the Mathematics Lecture Theatre, Imperial College of Science, South Kensington, S.W.7.*

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned

Assistant Lecturer in Civil Engineering in the City and Guilds College—The Secretary, Imperial College of Science and Technology, Prince Consort Road, South Kensington, S.W.7 (February 16)

Principal of Willesden Technical College—The Secretary, H M. Walton (T), 10 Great George Street, Westminster, S W 1 (February 16)

Head of the Engineering Department of the North Staffordshire Technical College—The Clerk to the Governors, Town Hall, Hanley, Stoke-on-Trent (February 17).

Lecturer or Assistant Lecturer in Mathematics in Westfield College, London, N.W.3—The Principal's Secretary (February 19).

Assistant Lecturer in Mechanical Engineering in the County Technical College and School of Art, Newark-on-Trent—The Principal (February 20).

Assistant Secretary at the Institution of Petroleum Technologists, Aldine House, Bedford Street, London, W.C.2—The Secretary (February 20).

Lecturer in Agriculture (Biology and Chemistry) in the School of Agriculture, Plumpton—The Director of Agriculture, County Hall, Lewes, Sussex (February 21).

War Department Chemists—The Under-Secretary of State (C.5), The War Office, S.W 1 (Quote Appts./19) (February 23).

Physicist on the staff of the Northern Coke Research Committee, Armstrong College, Newcastle-upon-Tyne—The Secretary (February 27).

Professor of Applied Mathematics in the University of Birmingham—The Secretary (March 1).

Musgrave Professor of Pathology in the Queen's University of Belfast—The Secretary (March 19).

Chemist in the R N Cordite Factory, Holton Heath—The Secretary of the Admiralty (C E. Branch), London, S.W.1. (Quote C.E. 77/1937.)

Oxford and Present Needs in Science

FOR some time, the University of Oxford has been faced with the task of finding £500,000 for pressing needs, largely connected with the extension of Bodley's library and prospective science and other buildings. It recently launched an appeal for help to its friends in Great Britain, in the Dominions and in the United States. The sum it is hoped to collect is about £1,000,000. Great trouble has been taken privately to make the need known to those capable of helping, and there is good hope that industry (now flourishing as rarely before), the surtax-payer, and the ordinary individual, between them, will find this large amount.

While it is true that those who contribute jointly the last £50,000 are most blessed of all, it is good that already the first three hundred thousand pounds have been given or are in sight. It is hoped that as much as £150,000 will come from North America, despite the damage due to the Mississippi floods, which rightly makes a first claim on much of American generosity. The needs for this appeal are, of course, quite independent of those so handsomely met by Lord Nuffield last year for the school of clinical research. They are very different needs and needs of long standing ; they cannot even indirectly be met out of the £2,000,000 provided by him. Lord Nuffield has recognized this point by generously subscribing a separate £100,000 to the present appeal.

The money received is to be administered by a trust, so that it will be guarded from inroads for 'general purposes', and devoted to the needs set out in the appeal. The extension of the Bodleian library will be the first charge on the fund ; the alteration or erection of buildings, mainly science buildings, will be the second. The rest of the money is to be used as capital or interest for developing research in any subject at all that looks promising, except such part of it as may have been earmarked at the wish of contributors. Oxford, while still highly cherished in our affections, is a changed place from the old days. It is now largely a University for the hard-working, middle-class student. Higher study and research have never been more ardently pursued over a wide field. In pure science for many years Oxford has done a large quantity of excellent work. With increased endowments for material in the physical sciences, and for men in the biological sciences, it could do much more without attempting to become a second Cambridge.

The most urgent of the scientific needs is a new physics building for Prof. F. A. Lindemann. His department has grown rapidly of recent years and latterly has become almost intolerable in the Clarendon Laboratory, now more than seventy years old. Within the next three or four years it is proposed to erect nearby in the Parks a new physics institute, equipped for the studies now being prosecuted there, and to adapt the vacated building for the Department of Geology. That department has had to exist in cramped quarters within the University Museum, which dates from 1860, and has suffered in recent years from the lack of leadership of its late head, who was in office until he was nearly ninety years of age. In the ampler space of the Clarendon Laboratory, with increased endowment, and with a new professor to be elected this term, this department should again take its rightful place in the University.

The second great need is for a University Institute of Physical Chemistry. There is at present no such place. For years the whole of the teaching and most of the research in this subject has been done in the college laboratories and cellars of Balliol, Trinity and Jesus Colleges. A fine spirit has been shown there and excellent work done—more, perhaps, than in many a university department with proper staff and ungrudged grants for material. But college laboratories are now at best makeshifts, rich only in improvisation. They are neither well endowed nor well equipped. They are small; not everyone is free to enter them and work there.

A new University building properly equipped and endowed is imperative, and it is fitting that Prof. C. N. Hinshelwood, who has succeeded Prof. Frederick Soddy as Dr. Lee's professor of inorganic and physical chemistry and is a leader of physical chemistry, should have as his place a proper official laboratory in which scattered researchers in this subject, collected from various parts of college and University buildings, may find a home. It is proposed to put up the building in the next four or five years in the Parks next to the Organic Chemistry Laboratory, if funds earmarked for it are forthcoming.

These are the immediate needs. Next comes that of the Physiology Laboratory, which some day must be rebuilt. It was originally put up in 1884, and the recent growth of the medical school must soon make change in it very desirable. Something also should be done to endow the Museum of the History of Science. A donor who might jib at seeing his comparatively modest contribution swallowed up in the general total might like to individualize it by helping this institution, which does good work on an exiguous income. It saves for the studies of future generations apparatus and other objects of historical value which might easily be lost in the midst of change.

Mention must also be made of the need for an extension of the Ashmolean Museum and for funds for archæological research, and, what is likely to be of far-reaching significance in the future, for research in the study of human society, social studies and allied subjects such as anthropology.

It is announced that the appeal has already produced a response averaging £2,000 a day. The promotion of the welfare and influence of the University of Oxford is worthy of the support of all who are concerned for the progress of learning in the present somewhat distracted state of world affairs.

Inter-Imperial Co-operation in Scientific Research

As already pointed out in the leading article in NATURE of November 7 last (p. 777), the proceedings of the British Commonwealth Scientific Conference were mainly concerned with inter-Imperial co-operation in supplying bibliographical information on the sciences relating to agriculture. Co-operative research in certain subjects was, however, suggested by various delegations from the countries represented. Sections of the report of the proceedings recently issued (Cmd. 5341. London: H.M. Stationery Office, 1937. 1*s.* 3*d.* net) deal briefly with such subjects of wide Empire interest as the transport and storage of foodstuffs, the control of insect infestation of stored products, the properties and utilization of wool, the collection and maintenance of plant material for crop improvement, and the control of damage by termites.

The Conference recommends that the contributions of overseas Governments to the Food Investigation Board of the United Kingdom should continue to be a matter for arrangement between the individual Governments interested in the transport and storage of foodstuffs, and that Governments should continue, pending further consideration, the payments they are making for work on wool at the Wool Industries Research Association's station at Torridon, Leeds. It also recommends that the Farnham House Laboratory of the Imperial Institute of Entomology be continued on an inter-Imperial basis by the countries interested in the control of insect pests by the use of parasites of these pests (so-called 'biologic control'), so as to maintain a small nucleus staff. Additional staff to deal with specific problems will be paid for by fees as occasion arises. Though stating that this method of controlling insect pests is still in its infancy, no reference is made to the need for research into it; the aim is to bring the cost of maintaining the Laboratory into close relation to the specific (applied) services demanded of it.

Similarly, in considering the work—largely pioneer work—on the control of insect infestation of stored produce carried out at Slough at the Stored Products Research Laboratory of the Imperial College of Science and Technology, the Conference, while recording its appreciation of the work, notes that in future the contributions from Empire countries towards general expenses will cease, and special inquiries will be paid for by fees; no inter-Imperial finance for research on this subject is suggested. No recommendations for financial co-operation on the various other subjects of wide interest discussed were made, beyond those included in the provision of bibliographical services and in the identification work of the Institutes of Entomology and Mycology.

Co-operation in scientific research, jointly financed on an inter-Imperial scale is, at the moment, in abeyance. It seems likely to remain so until its scope can be more clearly defined by the men of science concerned, and its planning entrusted to them.

Birds of the Greek Classics

A Glossary of Greek Birds

By D'Arcy Wentworth Thompson. (St. Andrews University Publications, No. 39.) New edition. Pp. viii+342. (London: Oxford University Press, 1936.) 12*s*. 6*d*. net.

THE first edition of this book was published forty years ago, and the author tells us that it is fully fifty since he began to write it. It is the work of a Greek scholar of wide knowledge and immense reading, as well as an expert naturalist. More, much more, than fifty years ago, he says in his preface, his father taught him that many a Greek word or name of a hero was foreign to Aryan speech. The merchant and the mariner had brought strange words home from overseas, and many a beast and bird and hill and river had kept its pre-hellenic name. Many old names of birds and fish are recorded by Italian scholars from the rich dialects of Italy, and new light is thrown hereby on obscure Greek and Latin words.

The author quotes in his preface a series of names of birds with strange non-Greek (probably Phœnician) names which, save one exception, it is difficult to identify with their present modern Greek names, or even to prove by their actual existence. What is, for example, σελευκὶς, τίτυγξ, σοῦσφα or τὰνταλος? Ὄρτυξ however, and πέρδιξ, differ very little from their present names and the foreign traveller who would designate them, as many of the other Greek birds, by their ancient name to a Greek peasant would be easily understood by him—unless the pronunciation was the Erasmian one or his accent too foreign.

So far as I can judge, the glossary of the names of birds in the book seems to be very complete, and the reader is amazed by the profusion of quotations from ancient authors—naturalists, historians, or poets, representing the reading and filing of a whole lifetime indeed. The mention of the corresponding names in the modern Greek language is extremely accurate, except in a few cases, where Prof. D'Arcy Thompson has been led into error by foreign observers describing Greek birds. For example, the neutral in modern Greek does not use the terminal syllable ον of earlier forms (ancient Greek of Byzantine), so that the modern name cannot be ὀρτύκιον or παγώνιον but is ὀρτῦκι and παγῶνι. Heldreich, from whom the author quotes, was a naturalized German, and was influenced by the ancient grammatical forms, or he heard the names from Greek purists who thought it probably more elegant to use classical forms instead of the popular ones, especially when informing foreigners. Such lapses, however, are rare and unimportant, and the correct forms are also mentioned by the author.

Ancient Greek literature, descriptive as well as imaginative, is luxuriously rich in its references to birds. Prof. D'Arcy Thompson borrowed lavishly from it, and I think that no quotation worthy of being referred to has been missed. Thus we have in the book a real treasure of quotations, which can be enjoyed by the naturalist as well as the scholar or the ordinary reader. Since the first edition of the book, the author has been able even to enlarge and to complete them. The whole romance of the life of Greek birds is displayed here in the etymology of their names (sometimes unknown, disputed or obscure), in epithets and phrases from authors or poets, in their description, nesting and migration, or with reference to mythical and legendary traditions connected with them. Some of the latter are really fascinating, and it is interesting to see them sometimes perpetuated to-day among the Greek people.

One of the most captivating chapters of the book is the long one devoted to the swallow, the bird of the returning spring, or as Sappho sings, "who brings again the new beauty". Superstitions are still connected with the bird. Modern Greeks are not reputed as bird-loving people, and it is probable that some of the species mentioned in the glossary have disappeared from the country. The swallow, however, remains the favourite bird Lucky is the house chosen by it for nesting when the spring comes ! It is a good omen. A daughter will marry during the year, or the mother will give birth to a male child—female ones being not generally welcome in Greek families, owing, I suppose, to the dowry to be paid when they are of age to be married. It would be curious to verify whether the swallow ever stays, as recorded by Pausanias, to nest in Daulis (now Davlia), the country of Tereus.

The hoopoe or hoope-bird, which persecutes the swallows (the Ἔποψ of ancient Greeks), plays an important part in the Aristophanean play and boasts there that he and his companions live "by grazing in the gardens on the white sesame, the myrtle, the poppy, and the mint". There are in the very obscure Tereus myth, as Prof. Thompson remarks, frequent indications of confusion between hoopoe and cuckoo, and the 'metamorphosis' is in part connected with the resemblance between the cuckoo and the hawk. In spite of confusions, the modern Greek τσαλαπετεινὸς is to be identified with Ἔποψ and is top the ἀγριοκὸκορας, found on Mount Taygetus.

To revert to the swallow, as I mentioned in an article on "Classical Aspects in Modern Greece" in the October issue of the *Quarterly Review*, I cannot affirm from personal experience that the charming and ever-young song of the swallow, preserved by Athenæus, survives until to-day, but reliable witnesses report that children in villages still sing it, scarcely altered, as they carry round a wooden swallow to announce the coming of spring.

Modern Greeks are not at all respectful of the sacred bird of the goddess patron of Athens, symbolizing her wisdom. Not only has the beautiful ancient word γλαὺξ, so strikingly reminiscent of the blue-eyed daughter of Zeus, been succeeded by the cacophonous κουκουβὰγια, evidently derived from the resemblance of the ululations of the owl to the call of the cuckoo (Md. Gr. κοῦκκος), but also they consider a visit from the Athenian bird to the roof of a house, flying there from its usual haunts on the slopes of the Acropolis, as a definite ill-omen. Somebody will die in the house so visited, and the superstition, more widespread in Athens than elsewhere, is confirmed by striking coincidences.

The nightingale, on the contrary, is most welcome and much cherished among Greek birds. Nightingales delight by their melodious concerts the tardy walkers wandering around the Royal Gardens during the summer in Athens, seeking some relief from the canicular heat of the day. As a matter of fact, nightingales amply justify the ancient epithet "deprived of sleep" attributed to them.

As people believe firmly that nightingales once captured and locked in a cage cannot survive but for a short time, the bird is generally respected and free, among trees and groves ; and it charms with its harmonious modulations the life of humble folk in the country as well as that of the opulent citizen enjoying the blessing of a private garden.

The

> Τιὸ, τιὸ, τιὸ, τιὸ, τιὸ, τιὸ, τιὸ, τιὸ, τιὸ,
> τριοτὸ, τριοτὸ, τοτοβρὶξ

of the nightingale is really spread over all in the most democratic way.

Colonus alas ! is no more the beautiful wooded hill, where according to the immortal Sophoclean song

> " . . . the clear voiced Nightingale
> Who hid in her bower, among
> The wine-dark ivy that wreathes the vale,
> Trilleth her ceaseless song" ;

but nightingales may be heard now even there.

It is interesting to note that in spite of the popularity of the nightingale, sweethearts are never referred in Greek folk-songs as ἀηδὸνι μου. This appellation applies, in a satirical mood, to prolix orators in the Agora or elsewhere. As for terms of endearment, comparisons used in the Greek folk-songs and even in daily life, are confined to partridges (=περδικά μου), pigeons (=περιστὲρα or περιστὲρι μου) and turtle-doves (=τρυγὸνα μου). I must say, however, that the names of these birds in Greek have a poetical flavour unknown in the corresponding names in Western languages. Or am I influenced in this belief by the frequent use of the words in Greek folk-poetry ?

The production of the new edition of "Greek Birds" by the Oxford University Press enhances the reputation of this famous printing-house—although I should prefer for the Greek text the new beautiful Greek type designed some time ago by Mr. Victor Scholderer and freely used now by the University Press. The author acknowledges gratefully the contributions made by the Carnegie Trust for the Universities of Scotland and his own University of St. Andrews for the production of the book, published by Mr. Humphrey Milford for the latter. To make easier for laymen the identification of birds mentioned in the glossary, the drawings of many of them figure in the text, and the innovation is most welcome.

DEMETRIUS CACLAMANOS.

Natural History of Glamorgan

Glamorgan County History
Vol. 1: Natural History. Edited by Prof. W. M Tattersall. Pp. xix+444+39 plates. (Cardiff: William Lewis (Printers), Ltd., 1936). 25*s*. net.

THIS handsome and well-produced volume is the first instalment of a projected history of the county of Glamorgan which was initiated in 1930 by the Lord Lieutenant of the County, the Earl of Plymouth. It is intended to cover the scientific interest of the county, and includes sections on the geology, climate and meteorology, soils, botany and zoology, written by voluntary workers, the whole being edited by Prof. W. M. Tattersall, professor of zoology and comparative anatomy in University College, Cardiff. This volume is to be followed by five others covering the industries, archæology, and ecclesiastical, political, economic and parochial history of Glamorgan. The scheme adopted is more or less that of the "Victoria County History", but the material of future volumes will be treated chronologically as a whole, and not as separate sections.

The first volume now published deals with the "natural environment of the county as a background to the history of man", and Prof. Tattersall is to be complimented upon setting a standard which, if followed in subsequent volumes, and in neighbouring counties, will result in an imposing contribution to the topographical history of Wales. In Glamorgan, the geological history has an important economic aspect owing to the material resources of the county, and this practical side is not forgotten in the biological sections, which include chapters on ornamental trees and shrubs under cultivation, and an account of the parasitic diseases to which cultivated plants and domesticated animals are subject.

In this connexion, attention may be specially directed to the section which discusses liver-rot in sheep. The distribution of four species of the primary host, *Lymnæa*, has been plotted during a period of ten years, and also the areas in which *L. truncatula*, the only important species economically, does not occur. The conditions favourable and unfavourable to this species, and its methods of migration, have been investigated. Ecological research of this character has significant bearings on the incidence of an important epizootic disease. Similarly, the survey of the soils of the area, accompanied by soil maps, is a useful contribution to the solution of the problem of soil classification. The greater part of the history, however, is devoted to the fauna and flora of the district—the work of various specialists. Besides the usual lists of species, ecological and historical notes are included, which add considerably to the usefulness of the records. This section of the work is valuable as a first attempt to assemble in print the fauna and flora of the county, but an inspection of the lists suggests that considerable additions have still to be made to them.

The volume is beautifully printed and illustrated, and there is a good index. It is to be hoped that the reasonable price which the Committee has wisely decided to adopt will ensure a wide circulation for the series.

F. J. C.

Another Dimension in Films

Colour Cinematography
By Major Adrian Bernard Klein. Pp. xi+350+29 plates. (London: Chapman and Hall, Ltd., 1936.) 25*s* net.

NOT all books are written by experts, in the sense that their authors know not only their special corner of their field but also what everyone else has done in that field and over a historical period of time. The present author complies with this definition for he gives valuable data respecting the system of colour cinematography in which he is most interested, and also collects and criticizes the entire range of systems and processes tried and developed up to date.

Major Klein is right in his contention that the release colour print must be used in standard projectors without any modification of the latter, beyond the obvious necessity of using specific carbons. It may never be assumed that the projectionist will carry out arbitrary instructions, precisely and time without number; such procedure will always break down and discredit the colour system. The remarkable freedom from breakdown in cinemas has been won by adhering to the limit of standardization. It follows that additive systems of colour cinematography are thereby ruled out, likewise two-colour systems, since not all shades can be objectively realized with a primary omission. We are left with Technicolor, Kodachrome, and Gasparcolor, the second being in use for 16 mm. film only, but has possibilities in simplifying the others for 35 mm.

The history of colour films is remarkable for the millions of pounds which has been expended on development; much of it, according to the author's contention, uselessly because of disregard of fundamental engineering limitations. The exquisite Technicolor, with its elegant, though yet secret, methods of imbibition printing, is criticized for using a key print and so causing some desaturation. The author's analysis of the complete problem, from the original lighting, colour, design, emulsions, processing, to final projection and the reproducing light, is clear and balanced, while his knowledge of patents and other people's work is impressive.

As an extension from technicalities, the author has wisdom to offer film directors in their use of mobile colours in their work, and some pungent ideas in cutting down existing production expenses to balance the greatly increased cost of film, lighting and the colour experts which are to come. His æsthetic pronouncements are derived from years of experience with colour-music, which did not fascinate the public. In the world of art, he suggests that Rembrandt was colour-blind and that the colour-film will be perfected when the colour is so natural as not to be noticed.

L. E. C. H.

Humanistic History

A History of English Life, Political and Social
By Amabel Williams-Ellis and F. J. Fisher. Pp. xvii + 120 + 132 + 163 + 160 + xviii + xxxii + 5 plates. (London: Methuen and Co., Ltd., 1936.) 8*s*. 6*d*. net.

We have so often in these pages deplored the absence of the scientific, popular and progressive spirit in the presentation of history, especially for educational purposes, that we hasten to welcome a new and most successful effort in the right direction. The book by Mrs. Williams-Ellis and F. J. Fisher has everything to commend it. The publishers' account on its 'jacket' does not exaggerate in the least.

The book is delightful and racily written; it gives the necessary outline of political development—all the kings and their dates are there—with a really good account of the progress of science and of the arts of living. It is most admirably and suggestively illustrated by all sorts of coloured sketches and diagrams, as well as prints and photographs. But it has more than all this, and something of still greater moment. It is inspired throughout by an intense sympathy for the life of the common people—the poor who have been at all times in history the vast majority of the population. The authors constantly insist on this, but they do it in no sense of despondency or of a desire for violent revolt. They see quite truly that the lot of the masses, which must be the main criterion of human progress, has improved immeasurably in the time and country which they review, mainly through science. They estimate England kindly but not excessively, and introduce at every suitable place the European or world-connexions and contrasts.

It is only practised writers who can do all this so deftly. Mrs. Williams-Ellis is a novelist, and the success of the present book is another proof of what has so often been proved before, namely, that the mere possession of a mass of knowledge is not in itself any guarantee of the power of presenting it effectively to others; and that for this particular purpose—and many others—a woman has special qualities not generally possessed by men—sympathy, tact and a knack of story-telling which in this case is combined with a very unusual and truly philosophic grasp of the hang of all the parts of the great theme. The authors thus show government, industry, science and social life bound together as they really are, and they do not entirely neglect—though this is undoubtedly the minor interest—the arts of beautiful expression. It is not too much to say that the authors have done in this book for English history much the same service which Arabella Buckley did in the last generation for science, in her "Fairy Land of Science".

It would be an interesting task to pick out a few specimens of the happy sayings and picturesque figures with which the book is full. The changes which 'Old Parr' would have witnessed in his life of more than a hundred and fifty years are a good example. But we have only space to deal with the one overwhelming question which will face teachers and scholars who will turn over its pages with delight. Will it enable the pupil to pass the School Certificate Examination? The answer must be, "Probably not". But could any interesting all-round presentation of the subject, in reasonable compass, ever hope to make its way through that barbed-wire entanglement in which our education is now confined ? The final answer must be some drastic change in the system.

Everyone should know the things which are here set out with so much charm, clarity of expression, humane tendency and fair balance of interest. That might well be required from all completing a course of general education by the age of sixteen years. For the rest, encouragement should be given to scholars with special interest to pursue further the study of special branches of history. This is the sphere to which diplomatic relations, constitutional details, plans of campaign and colonization properly belong. There also the progress of science and of technical inventions should find a leading place. F. S. MARVIN.

Absorption from the Intestine

Absorption from the Intestine
By Prof. F. Verzár, assisted by Dr. E. J. McDougall. (Monographs on Physiology.) Pp. xii + 294 + 12 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1936.) 21*s*. net.

THE Monographs on Physiology, published by Messrs. Longmans, Green and Co., Ltd., have performed a useful service in providing competent reviews of different aspects of a rapidly advancing subject. It is good to see that the series is to be continued under the editorship of Prof. Lovatt Evans, and it is hoped that these monographs will now appear more frequently.

Prof. F. Verzár of Basle has made many important contributions, during the last ten years, to our knowledge of absorption from the intestine. He writes with the authority of experience on nearly all aspects of this subject, and his book is fascinating to read. The first five chapters are devoted to a general discussion of the anatomy of the intestine, methods of research, and the physical and chemical forces involved. The remaining seventeen chapters are each devoted to a discussion of the absorption of one class of substance.

The author has tried to explain all the facts in terms of physico-chemical laws. In many cases he has been successful in finding plausible explanations; and in all cases he has made it clear that there is no necessity at present to invoke vitalism. The water in the intestine is in free communication with the body water; if heavy water is placed in the intestine it becomes diluted, within an hour, by an amount corresponding with the total water content of the body. The membrane is also freely permeable to crystalloids. It is practically impermeable to colloids, although minute quantities of unsplit proteins, or even visible particles, may occasionally be absorbed, probably through an accidental fault in the membrane. Absorption is controlled by diffusion and osmosis, and in the large intestine the hydrostatic pressure may be such that filtration is also an effective factor. The pumping movements of the intestinal villi may help to mix the intestinal contents, but it is probable that their main function is to pump absorbed fat into the large lymphatic vessels.

Hydrotropy plays an important part in the absorption of water-insoluble substances such as fat and calcium salts. This is defined as the property of some asymmetric, strongly surface-active, water-soluble organic substances of disintegrating water-insoluble substances to molecular complexes in which the hydrotropic molecules surround the insoluble molecule, and render it soluble and diffusible. Bile acids have this effect.

The rapid absorption of substances, such as glucose, which are useful foodstuffs, compared with similar substances, such as xylose, which are not, has seemed in the past to suggest that the intestinal mucous membrane is endowed with intelligence, and has provided a prop for vitalism. When the cells are killed they lose their power of discrimination. Prof. Verzár attributes these observations to the fact that glucose is rapidly phosphorylated in the cells of the living mucous membrane, while xylose is not. The diffusion gradient is therefore greater in the case of glucose than in the case of xylose. When phosphorylation is inhibited by monoiodacetic acid, the cells lose their power of discrimination. Similar explanations can be applied to the absorption of fats and other substances. This work has led to interesting experiments with the suprarenal cortex, which is known to affect the phosphorylation of sugars. Adrenalectomy destroys the selective absorption of glucose and fats; the injection of eucortone restores it. These facts are easily explained on the theory discussed above.

The theoretical and practical importance of this work is obvious. Prof. Verzár and Dr. McDougall have performed an important service to physiology in writing an authoritative account of work that is not so well known as it deserves to be.

Change of Life in Men and Women

By Dr. Marie Carmichael Stopes. Pp. xv+282. (London: Putnam and Co., Ltd., 1936.) 6s. net.

THIS book, like most others of the author, is popular in style and easy to understand. Moreover, it contains much common sense and a great deal of the advice given is thoroughly sound. For example, no physician would quarrel with the recommendation to avoid constipation. There are many other practical suggestions, and Dr. Stopes has done good service in directing attention to the help to be obtained from the work of the distinguished Spanish gynæcologist, Prof. Gregorio Marañón.

It is in dealing with the male climacteric that Dr. Stopes claims most originality, and though every medical man will agree with her as to the importance of studying this subject, serious doubts will be expressed as to the value of some of her advice and the accuracy of some of her statements. It is surely an extreme view to hold that "in the general physiology of man the testicles share their pre-eminent place with the prostate gland", and it is by no means certain that "the spermatozoa are stimulated to activity" by the alkalinity of the prostatic secretion. Again, it is doubtful what action the prostatic hormone possesses, or indeed whether there is a true hormone secreted by the prostate at all. Yet Dr. Stopes recommends the use of prostatic extracts to reduce the enlargement to which the prostate is subject. It is stated, further, that these and other extracts should be taken orally and not injected, the fact being ignored that most hormones (but not thyroid) are destroyed in the alimentary canal and never enter the circulation of the patient. In view of recent researches on the testicular hormones, it may confidently be predicted that in course of time, and probably in the near future, prostatic enlargement will be successfully treated, but Dr. Stopes does not allude to testicular extracts; and in any event further experimental data are required before definite recommendations can be safely made in a book addressed to the general public.

Isles of the Seven Seas

By Collingwood Ingram. Pp. 283+31 plates. (London: Hutchinson and Co (Publishers), Ltd., 1936.) 18s. net.

THE author is well known among horticulturists as an enthusiastic collector of cherries, and one who has also contributed to our knowledge of the genus *Gladiolus*. Furthermore, all his life he has been an observer of birds. Equipped with the twin lore of botany and ornithology, he has travelled widely, collecting and noting. For the purpose of this book, he has made a selection from his copious material, confining himself to islands he has visited. We leap from Tahiti to Coll and back to Sumatra, to Corsica, New Zealand, Ushant, and not least to Little Tobago; and if we have a feeling that Mr. Ingram is rather self-consciously trying to avoid the too smooth day-to-day narrative of orthodox travel literature, the device has its charm. Wisely he rivets our interest at the start by taking us to the South Seas.

Where the author has, if not quite beaten out the track himself, at least helped to widen it—and nowhere does he follow the crowd—he writes interestingly, and with real insight. His account of his father's experiment in introducing a very rare bird of paradise from the Aru Islands into Little Tobago is fascinating. Occasionally he imports scientific words into narrative in a slightly pretentious way; it would indeed be surprising if the moonlight even in Tahiti, where we expect everything to be glamorous, is really 'glaucous'! Such mannerism is the only blemish in an otherwise pleasant style.

The book is a record of personal impressions by a man of considerable feeling and knowledge, trained to observe accurately; a scholarly but not technical book for the lover of Nature.

Eisen- und Stahllegierungen: Patentsammlung

Erganzungsheft 1. Von A. Grutzner. Zugleich Anhang zur Metallurgie des Eisens in "Gmelins Handbuch der anorganischen Chemie", achte vollig neu bearbeitete Auflage herausgegeben von der Deutschen Chemischen Gesellschaft. Pp. v+425. (Berlin: Verlag Chemie G.m.b.H., 1935.) 44 gold marks.

THE publication in 1932 of a special volume containing in tabular form a list of patent specifications relating to iron and steel has proved to be so useful to research workers engaged in this industry that it has been necessary to prepare supplements of this collection on similar lines. The comprehensive nature of these tables, which cover the patent specifications of Germany, England, France, Austria, Switzerland and the United States, will be gathered from the fact that the present issue deals only with the interval between March 1932 and December 1934, and furthermore another special supplement to Part A of the volume on iron is being devoted to "Mechanical Properties of Steels", and will contain a complete bibliography extending over a very considerable period of time.

Epitome de Culturologia

Por el Dr. Imbelloni. (Humanior: Biblioteca del Americanista Moderno, Serie A, Tomo 1.) Pp. 320+8 plates. (Buenos Aires: José Anesi, 1936.) n.p.

THE series, of which this is the first volume, might well be symbolized by an inverted cone. The volumes of which it will be composed are classified into sections, beginning with general surveys of the various branches of the study of man, and narrowing and intensifying with each successive section, until in the sixth and last, attention is focused on the cultural history and ethnology of Argentina. This conception of a gradual intensification of interest as a basis of regional study, if execution does not fall behind, is wholly admirable. Dr. Imbelloni has given the series a good send-off in his survey of the study of culture and the methods of investigation by cultural distributions. Several examples of the study of areas of cultural distribution in relation to specific cultural traits are given in appendixes.

Geography and Economic Theory*

By Sir Josiah Stamp, G.C.B., G.B.E., F.B.A.

THOSE who are interested in geography as a subject to be expounded educationally must welcome every approach to it which may add to its effective rationalization and bond it into the main structure of knowledge. This is not a mere teaching device, for it may make teaching more difficult, if it is to make it more effective. It makes teaching more difficult if we have to go beyond the immediate neighbour in causation, to reach basic causation and fundamental reasons. To explain a geographical condition by an economic condition is immediate, but not fundamental. Some theory of economic action is implied, though it may be conveniently left unexamined and unexpressed—taken for granted. All such single economico-geographic couplets of facts taken together must ultimately conform to some theoretic principle, and have some common thread. If they do *not*, then there is no uniformity of causation, and no economic, still less geographical science. An economic explanation of a geographic fact is then no 'explanation' at all. The kind of theory which geography may involve, or which may aid geographic understanding, and help to make geography, already culturally basic to so many mental disciplines, a fully rounded science, is therefore the subject of this address.

Geography in recent decades has multiplied its descriptive classification or titles in a rather opportunist manner. No one bothers much about keeping or making the boundaries—they seem to be sufficiently well understood. Yet at the outset I find some uncertainty as to the true scope and purpose of 'economic geography'. Economic history is certainly not the history of economics, but quite clearly the selection of those facts in history which are of economic importance, or which can be accounted for only by economic tendencies and principles. But I am not sure whether economic geography is confined to describing the geographical aspects of physical and spatial facts which are of interest to the economist, providing him, so to speak, the bricks to build with, but quite indifferent to the use he makes of them. If so, how far does the economist really use them ? To what extent in constructing an edifice of economic principle does he rely on geographical material ? To what extent does he overhaul and recast principles to cover the wealth of material, with differences and similarities, which the economic geographer continually presents to him ? How far does he merely use this material by selection, to illustrate his point, or does he feel a responsibility for subsuming and accounting for the whole of it ? Is a geographical fact *ever* the awkward fact that kills the happy economic theory ? But perhaps the economic geographer thinks it is his own task to account for facts, for the presence or absence of features, for similarities and differences, by applying economic principles and tests. Perhaps he learns what facts to register and elaborate, by economic theories and differentials. Or am I again an idealist ? What, in fact, is the functional relationship between the two disciplines ? Whose task is it to do the work of establishing causation, in either direction ?

Economic geography must *begin* with physical environment, because these natural controls are dominant. So its first contributor is pure geography. But this is only the first of three classes. Variations of labour and capital are also important and these are covered by economic history and economics proper, not by geography. Thus complementary productions, in seasons or in female labour, are not factors derived from geography. The persistence of a factor through an early start comes from economic history. The data provided by Nature have to be handled by man, and therefore human motives are involved ; so the balance of marginal cost to himself of the effort and of marginal utility to himself of the product, or its market equivalent, must be made. Utility and value and psychic considerations have entered.

Geographers have been as active in adopting the term 'economic' without doing much distinctive with it, as economists have been inactive in using the term 'geography' for their basic data. In the composite volume, "The Trend of Economics", Prof. Weld has a section on "Regional Comparison and Economic Progress", in which he refers to the three trends now becoming clear : first, realistic studies as opposed to abstract analysis ; secondly, statistical presentation ; and thirdly, regional comparison. In elaborating the last, he details Mill's five canons of method applied to inter-regional data. "The economist of today finds himself face to face with the problem of the inequalities of standards of living in different regions. For example, India and China have not participated in the economic progress which has become conspicuous in some of the Western countries. Many explanations have been offered for the economic backwardness of regions in Asia, Africa and South America. Which explanation is nearest the truth? We do not know. It is time we were finding out. Scientific comparison seems the most obvious method. What is required is a thoroughgoing search for the *causes* of the differences in the separate regions." Surely this is economic geography in the truest sense, yet he never once uses the term 'geography'. The word geography does not appear in the indexes to the first forty years of the *Economic Journal*. The "Encyclopædia Britannica", 14th edition, has no mention of economic geography in its index. Palgrave's "Dictionary of Political Economy" (1896) includes an article on "Commercial Geography", which is for a large part economic history, but contains no reference to *causal* geography in the economic sense, except the conventional reference to England's natural advantages. It is very much the same story when we look in geography literature for economic theory. The index to the *Geographical Review* over a long period of years contains scarcely any reference to economics in its analytical or theoretical sense. Probably the nearest that it gets to it is in an article by Chisholm on "World Unity", where he postulates the tendency towards the equalization of economic development throughout the world in capital, in population density and in skill—an important economic generalization akin to the second law of thermodynamics and fraught with vital consequences in the field of foreign trade and also in the extent to which natural resources will be fully developed. But it is a generalization of his own which does not base itself on any recognized economic field. Modern works on realistic economics contain much geographical matter, and those on commercial geography, important summaries of economic factors. Thus a chapter in Seligman's "Principles of Economics" and one in Dr. Dudley Stamp's "Commercial Geography", dealing with the localization of industry, might even be changed over, without doing any real violence to the balance or trend of either work.

---

* Abstract of the presidential address to the Geographical Association, delivered at the London School of Economics on January 6

We may classify geographical explanations of economic facts, which are thus also quite often reversible as economic explanations of geographic facts, first as the simple static; second, as the simple dynamic; third, as the inductive static and fourth, as the inductive dynamic; and fifth, beings the most rare, as theory inductive and illustrative. The first, the simple or direct static, is the type best known to us, filling our commercial geographies and our realistic economic text-books. Its method is to account for one fact or set of facts by another set, not indeed in a connexion obvious until it is pointed out, but when stated, requiring or securing no supporting argument, no discrimination from other possible causes or connexions, and certainly involving no analytic and theoretic body of economic principles either to verify it or in itself to form an illustration. These often involve a certain element of history. In general, this class includes such statements as that a given port owes its prosperity to the fact that it lies on the trade routes between two wealthy or populous areas. "The completion of the Erie Canal in 1815 gave to New York, then a city of secondary importance, a position of undisputed pre-eminence" (Chisholm).

The second, or simple dynamic, class accounts for a *changing* set of facts by another set *changing* with it. Accounting for an important part of the grain trade of St. Louis, Chisholm says: "Here reside the merchants who handle a large part of the grain grown in the region to the west, including eastern Kansas and Nebraska. The nearest ports for that grain are Galveston and Houston. If the railways to these ports become congested, and are consequently disposed to charge too high rates, the merchants can apply for rates by rail or river to New Orleans, by rail to Baltimore or some other eastern port, or partly by water by the route here spoken of to New York" (p. 631). This is economic geography, but not economic theory. To provide economics with a problem for analysis, details of the change in traffic passing in different directions at different levels of freight rates and their fluctuations would be necessary. Or perhaps lessons in equilibrium between two types of transport, with different ratios of working costs to total costs, might be obtained therefrom. Chisholm provides a factual dwelling, but the economist is not yet dwelling therein.

The third, or inductive static class, draws lessons from a *number* of instances of the first class—for example, cases in which transport is involved. "With the increase of facilities and lowering of costs, geographical situation is yielding to the facts of artificially created location" (Seligman, p. 45). Similarly, population densities provide material for comparable generalizations.

The fourth, or inductive dynamic class, draws lessons from a number of instances of *changing* facts in sets or pairs with their correlations. This obviously is getting nearer to help for economic theory than any of the foregoing.

The fifth class goes further than the fourth if it brings the general principle that emerges into relation with analytic work, and perhaps produces generalizations which will 'work' as prophecies or further explanations. But I cannot find many clear examples in recent work. J. E. Orchard advanced along this line when he claimed that the geographic study of minerals is certain to involve economic theory and to make contributions to it. He illustrated by a geographic explanation of the agitation for the nationalization of mineral resources. Pressure comes through a demand for higher wages or lower prices. The emergence of a period of abundance in particular countries has the basis of different economic conceptions of property rights, and the threat of future scarcity in particular places has a like differential in the property concept. The period of abundance lay behind the *laissez faire* theory, and the current concept of property right is differentially distributed with scarce or abundant minerals.

Now, in the present state of economic geography, it seems to me that most progress is naturally being made in the third class. The photographs, so to speak, being taken in the first class, are being brought together for induction under the third. But as time goes on, new photographs will be taken of the same physical locations under the first class, and the endeavour to relate the old and the new will call for measurement and explanation of the change, and bring them under the second class. The accumulation of instances under the second class will then provide masses of material for induction under the fourth class. Here economic theory fully emerges, but not before. The economic theory is not based on static conditions—it is essentially related to incremental changes of cause and effect, or related effects; and only as geography registers changes over time can it be of full advantage to economic theory.

Turning to the geographical ideas of well-known economists, Adam Smith's "Wealth of Nations" was not so much a piece of abstract reasoning, as a systematic induction from history and geography, in what was really a piece of political propaganda of high wisdom. It was a great protest against nationalism, and therefore it was cosmopolitanism. But no man can be a cosmopolitan without being a geographer. It has more geographical references in proportion to its bulk than any later important work.

A famous example of the inductive method is John Stuart Mill's discussion of peasant proprietors. He does not elaborate from first principles the economic results of the whole produce of land going to the owner worker without a tripartite division into rent, profits and wages, for he calls it one of the most disputed questions in the range of political economy. But instead he examines conditions in Ireland, Switzerland, Norway, the Palatinate, Saxony, Prussia, Holland, Flanders, Channel Islands, France and Lorraine, takes the common factors and then makes generalizations. He declares, first, there is no necessary connexion between the form of landed property and an imperfect state of the arts of production; secondly, that the most effective use of the soil is not endangered; thirdly, that it is supreme in developing industry, intelligence, and frugality; and last, that it raises the standard of life, and does not unduly increase the numbers of the population.

We find no such rich geographic texture in the abstract reasoning of Ricardo, which was "unfavourable to any regional treatment". The German historical school introduced again ideas of relativity in time and space, but as we get down to modern times the text-books of "principles" are rather bare of geographic illustration. Seligman's "Principles" is well based on such facts, but even so objective a writer as Taussig in his "Principles" provokes the criticism of a geographic reviewer that he has very little geography. The latest highly analytical works of Pigou and Keynes are nearly bare of *geographic* facts.

Let us now lay out the field of economic theory on broad lines, and indicate in which quarters there lies most opportunity for geographic illustration or induction. It will be obvious at once that geography has no lot or part in a considerable range of it. Material objects need to have an appeal to human psychology before they are wealth. At least one half of the theory of value is psychological. A good part of invested capital is not geographical. Political and social institutions are of this order and, therefore, in the fields where these matters predominate geographic generalization is at a minimum. Where, however, we come to land, we should expect to find that if the theory, for example, of no rent land, and marginal land of various types, has any validity, we ought to be able to see these things objectively, and it is in relation to land and minerals, that induction from geographic facts should be most productive of theory or illustrative of it.

All questions of location and their effect upon production are capable of geographic illustration. Here is a generalization which is capable of economic analysis and certainly of illustration: "The geographic location of a manufacturing plant assumes an importance now that did not obtain when competition was less keen and almost any site would do. All the geographic factors have to be considered and a mistake in only one of them may offset good judgment in all the rest." Again, the geographer finds various methods of land utilization and describes them. The economist asks the question, why and wherefore—the causes. He finds certain uses bring misfortune; he seeks to impose conditions and so considers values.

When we get to the theory of demand and value, geography is quiescent. It is not, however, out of the question to see some possibilities. Anyone illustrating the principles of inelastic and elastic demand respectively, and taking salt and margarine as examples, might extend the study into the relative stability of employment in geographical areas supplying one as compared with those dependent on the other, to account for their differences. This would be an excellent geographic verification or illustration of the theory. The principle of substitution might well be illustrated by the rise to popularity of particular commodities supplanting others the costs of which had become dearer, relatively, if not absolutely. This change means a change in the economic statistics of geographical areas, which can be examined and stated.

International trade proceeds on the theory of comparative costs (with certain important modifications) and it shows that it is quite possible for *a* to export to *b* commodities in which *b* has the greater natural advantage, provided that *b*'s natural advantages in another commodity are even greater. This ought to be susceptible of verification by reference to geographic facts.

Geography has little concern with money, banks or the technique of trade, and productive methods, but I would not conclude that the economist can make no use of geography at all in these fields. Atkinson says: "But if the metric system gives Germany an advantage over Great Britain in South American markets, it becomes to that extent a factor in the Geographic division of labour—that is, it tends to locate the economic complement of the wheat fields, and cattle ranches of Argentina in Germany rather than England"

Then again, banking systems may affect geographic facts: if the bank reserve system in America draws money from country to cities and gives them a lower interest rate, then it becomes a factor in concentrating industries, and determining the geographic division of labour.

Technical production is not economic geography. But if the Bessemer process causes migration of the steel industry to areas where the ores are free from certain impurities, it is part of economic geography.

A few years ago the American Economic Association had a round table discussion on the various relations between economics and geography[1]. It covered the geographic basis of agricultural production, land economics, economic concept of property in minerals, the study of pioneer belts, and geography in foreign trade prospects.

This probably expresses fairly the field of geography which actually lies within the field of economic theory, but the range of the latter is extensive and may—to reverse the metaphor—throw valuable side-lights at unexpected points of geography. But economics, though now highly specialized, is really one and indivisible. The geographer who aims at strengthening his grasp of causality, especially for expository purposes, by learning economics, would do well to cover the whole field first, in a preliminary way, and then specialize on the particular applications to which our analysis has led us. The economist who would keep his feet on the ground, even if his head is in the clouds, by realistic treatment, will get no such mitigations of his task from the geographer—like John Wesley, he will take the whole world for his parish.

Constitution of the Earth*

By J. H. Reynolds

THE behaviour of materials such as granite and basalt can be tested in the laboratory up to a pressure of 30,000 atmospheres, or, as engineers would say, about 200 tons to the square inch. This corresponds to a depth of 120 km. in the earth's crust, but what are the conditions of matter at pressures of 10,000 tons to the square inch or thereabouts, which presumably must obtain near the centre of the earth? Then with regard to temperature, we know that near the surface of the earth in Europe this increases generally with depth by about 30° C. per km. The rate of increase differs considerably from one point of the earth's surface to another. In North America it is three quarters of this amount, and in South Africa only about one half. In regions where volcanic activity has taken place in recent geological times, the rates of increase are abnormally high. In a boring almost a kilometre deep at Budapest a temperature of 69° C. was reached at the bottom. In Tuscany and other places in Italy a similar rate of increase has been found. If we take an average and extrapolate from this, we find that at a depth of something like 50 km. we reach a temperature of 1,400° C.,—enough to fuse all but the most refractory substances.

---

* Extract from the presidential address to the Royal Astronomical Society delivered on the presentation of the Gold Medal to Dr Harold Jeffreys on February 12.

But is it safe to extrapolate, and would not the increase in pressure alter the fusing point and also the rigidity ? This undoubtedly takes place, for earthquake foci as deep down as 400–500 km. have been inferred from the various types of seismic waves and their times of travel to different stations. An earthquake focus at such a depth presupposes that the material there is strong enough to fracture, so we must assume that notwithstanding the probability of a temperature certainly equal to, and probably much more than, the free fusing point, the material, whatever it is, has still considerable strength.

Then we have the complication introduced by radioactivity. A certain proportion of the earth's internal heat, at any rate in the outer crust, is due to the presence in igneous rocks of radioactive metals such as uranium and potassium. What proportion of the earth's internal heat is due to this cause, and how much to primeval heat still remaining from the time when the whole earth was a molten-globe ?

The deductions which geophysicists can make as to the internal structure and composition of the earth, below such an insignificant fraction of the earth's radius as a few kilometres, must therefore be in the nature of extrapolations, and the validity of the conclusions reached depends entirely on the assumptions made as to the behaviour of various substances under conditions of heat and pressure which are for the most part far beyond the limit of verification in the laboratory.

Notwithstanding these formidable difficulties, Dr. Harold Jeffreys has boldly grappled with the many problems involved, and has presented us with a conception of the earth's interior which fits in remarkably well with the known data. He first of all postulates a shell which behaves mechanically as a solid, reaching down as far perhaps as 3,000 km. This shell is of a density which increases from the surface downwards, the surface density being about 2·7 and the lowest layer about 5. It is worth noting at this point that Jeffreys' work is quite inconsistent with Wegener's hypothesis of the continents floating on a viscous magma comparatively near the surface, and it is equally opposed to the tetrahedral theory of the formation of the continents. There is a discontinuity between the central core and the shell in the way of transmitting earthquake waves, and as the core is apparently incapable of transmitting distortional waves at all, it is concluded that the central core is still in a molten condition. Its density is only consistent with the heavier metals, and iron is probably its principal constituent.

From a detailed study of the times and rates of travel of the two main types of earthquake waves, the primary and the secondary, with their associated surface waves, it is suggested that the principal constituent of the earth's solid shell is olivine, as this mineral is of about the right density required. But this does not extend to the surface, where there is a layer of granite under the accumulated sedimentary rocks of the continents, and a layer of denser rocks, presumably basic, lies under the oceans. The granitic or continental layer is estimated to be about 10 km. thick, and two other layers of about the same thickness, but discontinuous in their density, may lie between it and the lower shell of olivine or its equivalent.

Stoneley has also made an estimate of two discontinuous surface layers, and he finds a thickness of 12 km. for the granitic layer and 24 km. for the intermediate layer. There seems to be another discontinuity of density at something like 400 km. down.

In substances that contract on solidifying, the fusing point is raised by pressure, so that at great depths materials must be still solid at temperatures much higher than the fusing points at the surface. This rise in the melting point due to pressure at low pressures is about 3° per kilometre, at greater depths probably somewhat less than this. While the earth was molten, the temperature would increase downwards, but the fusing point would increase faster, and as the whole cooled at a uniform rate, so solidification must have taken place from the bottom upwards. If the core is of metals, which have a lower fusion temperature than the basic silicates of which the outer shell probably consists, then the core would remain liquid, while the outer shell, still liquid at the surface, would be solid at great depths. The core, therefore, got trapped under a layer of badly conducting silicates, and its temperature has not dropped greatly since it was originally formed. On this hypothesis the whole process of solidification did not take more than some tens of thousands of years.

It is now established that the earth's surface temperature is practically controlled by solar radiation alone, and it has been so during the greater part of geological time. If we find evidence of variation in surface temperatures in past geological epochs, we must attribute the variation either to changes in the sun's radiation or to altered meteorological conditions. I find it difficult to imagine altered general meteorological conditions without a corresponding cause in solar radiation.

The small amount of heat still leaving the earth by conduction from the interior is partly a relic of the primeval heat from great depths, and partly heat generated more recently by radioactivity. The radioactive metals, uranium, thorium and potassium are found in all surface rocks in minute but measurable amounts. Granite contains a greater proportion of these radioactive metals than the basic rocks. In average granite the rate of generation of heat is found to be $1{\cdot}3 \times 10^{-12}$ calories per cubic centimetre per second, while for basalt it is only $0{\cdot}50 \times 10^{-12}$ calories. Small as these amounts are, it is found that the total heat now being lost from the earth by conduction can be supplied by a layer of granite 20 km. thick over the whole surface. This leaves nothing to be supplied from greater depths, and fixes an upper limit for the thickness of the granite layer. But it has been found from the study of near earthquakes and surface waves that the granitic layer is only 10 ± 3 km. thick There must be, therefore, as large a proportion of radioactive elements in the upper 10 km. as in all the rest of the solid shell beneath it. This leads to the conclusion that radioactivity decreases rapidly with depth, and further that the radioactive metals became concentrated in the surface rocks in the early history of the earth. In any event, volcanoes and subterranean igneous phenomena such as intruded masses of granite and basalt must have some source of heat not a great distance down to explain them, and radioactivity in the earth's crust does this.

Obituary Notices

Dr. F. S. Macaulay, F.R.S.

FRANCIS SOWERBY MACAULAY, who died at Cambridge on February 9, aged seventy-four years, was for many years mathematical master at St. Paul's School and will be remembered by generations of pupils, not a few of whom became distinguished mathematicians; he also produced original mathematical work of high quality, in a field little cultivated in England, the general theory of algebraic polynomials.

Macaulay was the son of the Rev. Samuel Macaulay, and was born at Witney, Oxfordshire, on February 11, 1862. From Kingswood School, Bath, he went up to St. John's College, Cambridge, in 1879, and was bracketed eighth wrangler in Parts I and II of the Mathematical Tripos in June 1882, the first year of the divided tripos. In the January following he was placed in the third division of the new Part III, to which only wranglers were admitted. After two years at his old school, he was in 1885 appointed to a mastership at St. Paul's, where he remained until his retirement in 1911. Before going to Cambridge he had passed the London Matriculation with honours; he took the London B.Sc. in 1891, and the D.Sc. in 1897. He published, in 1895, a text-book on "Geometrical Conics". He was an active member of the Mathematical Association, being for many years an associate editor of the *Mathematical Gazette*. After the Great War he went to live in Cambridge, where, in 1923, he married Norah, widow of Mr. G. A. Matthew.

Macaulay approached his algebraic research from the geometrical side, the theory of algebraic curves. His first paper, of fifty pages, published in the *Proceedings of the London Mathematical Society* (**26**; 1895), is concerned with the number of conditions presented by a finite set of points in a plane, grouped in 'clusters' of any degree of complication, in the determination of algebraic curves of given order. This led on to an algebraic investigation of the intersections of curves at multiple points and to a thorough reinvestigation of the well-known theorem of Noether on the form of the equation of a curve which passes through the intersections of two curves, with the generalizations of Lasker. So his interest was aroused in the general theory of modular systems, that is, of polynomials, in any number of variables, expressible in the form $A_1F_1 + \ldots + A_rF_r$, there the F's are given polynomials and the A's are arbitrary polynomials. A series of papers in the *Proceedings of the London Mathematical Society*, the *Transactions of the American Mathematical Society*, and the *Mathematische Annalen* was followed in 1916 by his Cambridge Tract, "The Algebraic Theory of Modular Systems", in which he gave an account of the whole subject, filling in many gaps in the proofs of his predecessors, and adding considerably to the theory.

Macaulay's work attracted more attention in Germany than in Great Britain, and it was not until 1928 that its first-rate quality was recognized by his election to the Royal Society. In his later years, in Cambridge, he lived a retired life, and was not often seen in College or in society, but he always showed a keen interest in the work of the younger mathematicians on the algebraical and geometrical side, and was a frequent and welcome visitor at seminars in these subjects.

We regret to announce the following deaths:

Dr. Frederick V. Coville, botanist of the U.S. Department of Agriculture, known for his work on the relation of plant growth to soil conditions, on January 9, aged sixty-nine years.

Sir Reginald Craddock, member of Parliament for the Combined English Universities since 1931, on February 10, aged seventy-two years.

Dr. Alfred Daniell, author of the well-known "Text-book of the Principles of Physics", on January 12, aged eighty-three years.

Prof. Max C. W. Weber, For. Mem. R.S, formerly professor of zoology and comparative anatomy in the University of Amsterdam, on February 7, aged eighty-four years.

News and Views

British Industries Fair

THE 1937 British Industries Fair opened in London and Birmingham on February 15 and will remain open until February 26. The organizers tell us, as they have been able to tell us each successive year for many years past, that it is the biggest and most impressive fair that has yet taken place. There is no reason to doubt the claim; the record area occupied by the exhibitors' stands last year has been exceeded by more than 10,000 square feet. No doubt, over and above the increased number of exhibits due to the natural growth of industry and to the recent improvement in trade generally, the fact that this is Coronation year has had a considerable influence upon the record figures. There are more than 1,500 exhibitors detailed in the catalogue, of whom the largest number (78) are from London and the two smallest groups are from Glasgow (12) and from Edinburgh (7). No less than sixty countries are represented by their trade buyers. Holland heads the list, and other countries well represented are Germany, Belgium, France, Denmark, the United States, Sweden and Poland. Italy also is well represented, but Spain, which last year sent a strong contingent of buyers, is this year a notable absentee, for reasons which will be obvious. As before, the hardware and heavy industries section of the fair is held at Castle Bromwich, Birmingham.

OLYMPIA accommodates exhibits of what may perhaps be called the lighter industries, such as chemicals, glassware, leather, scientific instruments, foodstuffs, paper, toys and games, and musical instruments. The textile, furniture and allied industries have their exhibits at the White City. It should be noted that only goods manufactured or produced within the British Empire are permitted to be displayed, and no exhibitor may exhibit articles other than those of his own manufacture. We hope to publish in our next issue an article directing attention to the prominent features of the exhibits that can be regarded as being predominantly scientific. Meanwhile, it is of interest to note that the printers of NATURE, Messrs. Fisher, Knight and Co., Ltd., have installed at Olympia a complete printing works demonstrating block-making, type setting, machining and binding, and volumes of NATURE are being exhibited.

New Equipment for the Royal Air Force

THE publicity recently given in Parliament to the delay in the aircraft building programme scarcely gave due importance to one of its fundamental causes. This expansion in quantity required comes at a time when a radical change is taking place in aircraft constructional methods, made necessary by recent research having caused aerodynamic design to demand a somewhat different exterior form. A continued increase in engine-power available, added to improvements in design reducing resistance and giving greater speed ranges, have enabled the speed of flight to increase so that up to 300 miles per hour can be contemplated for certain types of aircraft which constitute the quite normal equipment of the R.A.F. At such speeds as this, the air friction at the surfaces of the various component parts of the machine becomes a much greater proportion of the total resistance than at the lower speeds used hitherto. It now becomes vital to have both correct aerodynamic shape and smooth surfaces if reasonable efficiency is to be attained. In the past, most aircraft has consisted of girder frameworks taking the loads, covered by linen fabric the function of which was to give an airtight surface to react to the air pressure. It is not possible to avoid this cover sagging between its points of support to a certain extent, thus spoiling the correct aerodynamic form. Also the method of attachment, usually sewing, set up excrescences on the surface the roughness of which was appreciable. Thin metal sheeting, with flush riveting, is the obvious improvement upon this, but its weight is intolerable unless it can be made to take some of the induced loads, and allow the interior structure to be correspondingly lighter.

THE development of this conception has led to the use of 'stressed skin' construction in modern machines, in which both the wings, control surfaces, and the body are formed of strong and hard sheet metal, withstanding the majority of, and in some cases all, the loading. Although the theory of the design of such structures is now becoming fairly well known, the workshop practice of building them in quantities is by no means well advanced. The adoption of these new designs has necessitated the development of new workshop technique and the design and production of new tools and equipment, which has obviously been especially difficult for those firms that are still working on the older type of construction, which is by no means obsolete or even incorrect for certain types of slower-speed machines. It is probably not unfair to say that the speed-up in aircraft production that has taken place in some countries during the last few years began too soon, and has resulted in a large equipment of machines that are already obsolescent.

Dr. Thomas Midgley

THE Perkin Medal of the American Section of the Society of Chemical Industry has this year been awarded to Dr. Thomas Midgley, who has achieved world-wide fame for his discovery of tetra-ethyl lead as an anti-knock agent. This, it should be emphasized, was no chance discovery but the result of systematic trial following a study of the periodic system, the final finding that the lead derivative would solve the problem being predicted beforehand. To-day 'ethyl' is added to seventy per cent of all the petrol used in America, and the increased horse-power thereby generated amounts to a very large figure. In a characteristic address given at the time of receiving the medal, Dr. Midgley told the story of his more recent discovery of a compound of carbon, chlorine and fluorine, $CHCl_2F$, to be used as a refrigerant, which is non-toxic and non-inflammable. Apparently he was told of the need for a new refrigerant over the telephone, and with the aid of two colleagues, the use of a chemical library and some deductions from the periodic table, arrived at the probability that the above fluorine compound might prove non-toxic and suitable. Small quantities were prepared from various samples of available starting material. The first batch was pure and proved non-toxic; in the others the raw material proved to be contaminated and gave toxic products, which, however, could be purified when this fact was realized, and became non-toxic. Three days' work sufficed to solve the problem and to give the refrigerating industry a new material which is expected will prove of outstanding importance in its development.

Gottfried Treviranus (1776–1837)

GOTTFRIED REINHOLD TREVIRANUS, the eminent physiologist, the centenary of whose death occurred on February 16, was born at Bremen on February 4, 1776. He studied medicine at Gottingen, and while an undergraduate wrote an essay on nerve power and its method of action. He qualified in 1796 with a Latin thesis on the reform of physiology, and settled in his native town where he was made professor of mathematics and medicine in 1797. The rest of his life was divided between the practice of medicine and scientific research, though the latter claimed most of his attention. His medical publications were of little significance, being chiefly concerned with the prevention of salivation in the mercurial treatment of syphilis and animal magnetism in Bremen. On the other hand, his biological work was of considerable importance, his principal publications of this kind being entitled "Biology or the Philosophy of Living for Natural Philosophers and Doctors" (6 vols., 1802–22) and "Manifestations and Laws of Organic Life" (2 vols., 1831–33). In addition to physiological research, he devoted special attention to microscopical anatomy of invertebrate animals, especially molluscs and insects. In collaboration with his brother, Ludwig Christian Treviranus, a well-known botanist and medical man of Bonn (1779–1804), he published four volumes of miscellaneous work on anatomical and physiological subjects (1816–20).

Auroral Display and Radio Disturbance

THE probable occurrence of an aurora on January 7, twenty-seven days earlier than the notable display on February 3, as recorded in last week's issue of NATURE (p. 277), is confirmed by Mr. W. N. Craig, of The Manse, Fortrose, Ross-shire. On January 7, between $16\frac{1}{2}^h$ and 19^h U.T., Mr. Craig, who was listening on the 14 Mc. amateur band, found that reception from long-distance stations in South Africa and on the west coast of America, which was good at first, suddenly deteriorated at 18^h 40^m so as to render the signals practically unintelligible by "a very rapid flutter". At 19^h 30^m, Mr. Craig, on looking outside, found that a conspicuous auroral display was in progress. An arch extending from north-east through north to west was beginning to break up into a series of streamers, and at 19^h 45^m, after an apparent increase in auroral activity, a corona formed for a few minutes a little to the north-west of the zenith. The display then decreased rapidly, but was partially renewed as a quiescent arch extending from east-north-east to west-north-west from 22^h until after $23\frac{1}{2}^h$. As mentioned in the previous note, the magnetic traces on January 7 recorded at the Greenwich magnetic station at Abinger show distinctive movements between 19^h and 20^h U.T. The extreme ranges, occurring at about 19^h 32^m, indicate a local increase in the intensity of the earth's magnetic field of about 130 γ accompanied by an easterly swing in declination of about 20′.

Science and Building Exhibition

THE Science and Building Exhibition which is to be held on March 1–25 at the Building Centre, 158 New Bond Street, London, W.1, is being arranged at the invitation of the Building Centre, by the Department of Scientific and Industrial Research. The object of the Exhibition is to illustrate the work being carried out by the various organizations controlled by the Department, or associated with it, of interest to the building industry. The exhibit provided by the Building Research Station will deal with such subjects as concrete, plastering materials, fire resistance, bituminous materials and building units for walls and roofs, an exhibit by the Fuel Research Station illustrates work on domestic heating. The Forest Products Research Laboratory is dealing with wood preservation, dry rot, resistance of timber to abrasion, timber seasoning and insect damage. Interesting exhibits are being shown by the National Physical Laboratory on illumination in buildings, acoustics and engineering investigations such as wind pressure on structures and mechanical tests on structural steels, etc. The exhibit by the Water Pollution Research Board and the Department's Chemical Research Laboratory deals with water softening, the removal of dissolved salts from water and contamination of water by lead. British marbles will be dealt with in an exhibit provided by the Geological Survey of Great Britain. The Industrial Research Council of the British Iron and Steel Federation will show models of steel-frame buildings intended for working-class flats, and the applications of foamed slag as an aggregate for lightweight concrete. An exhibit by the Non-Ferrous Metals Research Association deals with galvanizing and zinc coatings, and recent investigations on the frost-bursting of water pipes. The Cast Iron Research

Association, the Paint Research Association and the Rubber Research Association will also be represented. Lectures have also been arranged to take place at 8 p.m. on March 3, 10, 17 and 24.

Palæobiology and Biostratigraphy

DR. H. G. SCHENCK has published an exhaustive monograph of "Nuculid Bivalves of the genus *Acila*" (Geological Society of America, Special Papers No. 4; 1936). A critical descriptive catalogue of the twenty-five known species and varieties is arranged in the order of their age, from Cretaceous to Recent, and is illustrated by eighteen admirable plates which give a complete iconography of the genus. The systematic part of the work is preceded by the morphology of the shell and by an account of the anatomy, habits and habitats of the living animal. The terms 'paleobiology' and 'biostratigraphy' are used hopefully, but no radically new methods are apparent to correspond with them. Ever since palæontology has been rationally studied, its best workers have used the anatomy, the habits and habitats of living creatures to explain the debris of their precursors. The method requires caution, for some animal genera have changed their mode of life. The marine mollusc *Pholadomya*, for example, is now abyssal; in Jurassic times it lived in shallow water and, so late as the Eocene, it is found in sediments which give no indication of very deep seas. Dr. Schenck was led to this study by the problems of the Oligocene in the United States Pacific coastal areas. His results help to solve these problems, not by any *a priori* palæobiology, but by the accurate delimitation of fossil species and by showing that they are associated with distinct faunas in a sequence of strata. This is not a new method, but it is the only sound one, for all our knowledge of the succession of forms of life is from stratigraphy, which, somewhere or other, must be based upon visible superposition. Terms like 'zone', 'age', 'epoch' are discussed. Palæontologists did not invent these words, which are still current in ordinary speech, so that we can doubt the wisdom of restricting their meaning, for their common, vague sense is sure to lodge in runaway minds and cause confusion.

Investigation into Brood Diseases of Bees

IN May 1934, an investigation into the brood diseases of bees was commenced at Rothamsted Experimental Station, the British Bee-Keepers' Association undertaking to supply half the annual cost of the work (£250 per annum) and the Agricultural Research Council the remainder. As a result, Dr. H. L. A. Tarr was appointed, and has worked continuously on the problem since that time. He has confirmed the fact that American foul brood is caused by a spore-forming organism, *Bacillus larvæ*, and that its incidence is independent of the strength of the bee colony. European foul brood, on the other hand, is a disease which usually affects weak colonies of bees early in the brood-rearing season, and is probably caused by *Bacillus pluton*, a curious organism which has so far resisted all attempts made to cultivate it, in association with other organisms. He has also shown that a third condition known as addled brood is very, prevalent in Great Britain, and has constituted almost one third of the cases of brood disease sent in for examination. The Bee Research Committee at Rothamsted and the British Bee-Keepers' Association are unanimously of the opinion that the investigation should be continued, particularly in connexion with methods of treatment, but the latter have asked that Rothamsted should collect the contributions directly. The Agricultural Research Council has sanctioned an increased grant of £300 for the current year on condition that a sum of not less than £250 is collected from other sources. In the circumstances, Rothamsted Experimental Station is making an appeal for contributions from interested individuals in order that this important investigation may be continued.

Sperm Whale at the Natural History Museum

THE skeleton of the sperm whale stranded at Bridlington on January 25 has now reached the British Museum (Natural History). The animal from which the skeleton was taken was a male 59 feet in length. In the sperm whale, the male is fully grown at about 65 feet, whereas females have not been recorded exceeding 40 feet in length. The sperm whale or cachalot belongs to the division of the Cetacea known as toothed whales or Odontoceti. The Bridlington animal had thirty pairs of teeth in the lower jaw (all unfortunately removed by souvenir hunters) and three small tooth vestiges on one side of the upper jaw. The whole skeleton weighed between four and five tons, of which weight the skull accounted for more than three tons. The sperm whale is not a common animal in British waters, only about six strandings having occurred in the last twenty-five years. It prefers the warmer tropical and subtropical seas. Sperm whales stranded on British shores are almost invariably large old males, and it has been suggested that they are animals which have been driven out from the main herd by younger and more vigorous bulls. The present stranding is therefore rather remarkable. The Museum is informed by coastguards of all Cetacea stranded on the British coasts, and specimens are obtained whenever desirable and practicable. On an average, there are about sixty such strandings in the year. Stranded whales, being "Fishes Royal," are the property of the Crown, and are handed over to the Museum by the authorities concerned.

Botany in China

IN a paper presented at the annual conference of the International Faculty of Sciences, held in London on January 29–30, Prof. H. H. Hu described the progress of botanical sciences in China. Botany in China is a very modern study, having a history of only a quarter of a century, though, of course, the medicinal study of herbs in ancient China is well-known. At present, taxonomy takes pride of place, which is natural in a country so rich in botanical resources. During the past fifteen years, six institutes have been established which are carrying out important exploration work; and this has resulted in a rich harvest, including many rare specimens. Prof. Hu himself is attached to the Fan Memorial Institute of Biology which was established in 1928, and is wholly devoted to the taxonomic study of the flora and fauna of China. The botanical section carries out exploration in Yunnan, during which many new genera have been discovered. Monographic studies of ferns and flowering plant families are also being made, which are published in the bulletins of the Institute. In connexion with systematic botany in China, three botanic gardens have been established. The other branches of botany are still at the pioneer stage. Valuable work is being done on freshwater and marine algæ, mycology and morphology. We would, however, like to see further recruits to the small band of Chinese botanists studying plant physiology, ecology and genetics, in order that the whole subject may become more balanced, since all the subdivisions of the science are so interrelated that satisfactory progress in the whole is not easy without equal progress in each part.

Plastics for Use in Electrical Engineering

IN a recent paper (*J. Inst. Elec. Eng.*, Oct.), A. R. Dunton gives an account of recent advances in the technique of producing plastics. This word is now used for describing 'moulded compounds' which produce intricately shaped articles in a suitably constructed mould under the influence of heat and pressure. The accuracy obtainable by this method has aroused great interest in both mechanical and electrical engineers. There are many fabricated articles still being sold which could be replaced conveniently and economically by suitable mouldings. In Germany, many plastics are employed, and the technical specifications made ensure that they are suitable for the purpose for which they are to be used. The articles supplied are stamped with an identification mark and the maker's number. The national laboratory in Berlin has the right to take samples at any time without warning, and if the test results are not satisfactory, the maker's name is deleted from the approved list published periodically by the laboratory. The British Standard Specification was published by the B.S.I. in 1933; but unfortunately it makes no attempt to define the characteristics of arc-resisting or high-temperature materials. The performance of nearly all plastics is coupled in practice with high temperatures. A method of making rapid tests advocated by Prof. Marten of Berlin is described. It determines without difficulty the softening point of plastics. In a paper in the same issue by A. Caress, an attempt is made to classify typical plastics into those for 'hot service' and those for use at moderate temperatures. The author says that if the electrical industry will specify clearly what it requires, the plastics industry will rapidly develop suitable materials. He states that there is a very large range of new plastic materials to be discovered and examined.

Sterilized Catgut for Surgical Use

IN a Circular (No. 1563. Price 1*d.* net) and accompanying Memorandum (Memo. 199. Med. Price 2*d.* net. London: H.M. Stationery Office) issued to county, and county borough, councils, the Minister of Health directs attention to the responsibility and risk attached to the use of imperfectly sterilized, or unsterile, catgut for surgical purposes. Several groups of cases of tetanus infection have recently occurred following surgical operations in which catgut had been employed, in some of which the infection was definitely traced to the catgut. Under the Therapeutic Substances Act, 1925, and Regulations, 1931, the manufacture for sale and the importation of sterilized surgical ligatures and sutures is prohibited except under licence from the Minister of Health, and the granting of such licence is conditional upon routine testing of samples of the product for sterility, and upon control and inspection of the process of manufacture. When 'sterilized surgical catgut' is employed, the patient may be regarded as adequately safeguarded from tetanus infection, but in many hospitals 'raw' unsterile catgut is bought for use. Such catgut is not controlled under the Therapeutic Substances Act, and is 'sterilized' in the hospital itself by a process which may or may not be satisfactory. The Memorandum describes the method of preparation and of sterilization of catgut. Respecting the sterilization process, heat is sometimes employed, but needs great care, and an aqueous solution of iodine, with or without preliminary treatment with hydrogen peroxide, is efficient and widely used. Most other sterilizing agents are inefficient, or damage the gut.

Yale University Publications in Anthropology

THE second issue of collected papers in anthropology, published by Yale University (London: Oxford University Press. 11*s.* 6*d.* net) under the editorship of Dr. E. Sapir and Dr. Leslie Spier, contains six papers, of which five deal with various aspects of the ethnography of North America. Students of primitive music will welcome an attempt to produce order in a subject to which no little attention has been given in the field, but to which comparative study has still to be applied systematically. This is a regional survey of the music and musical instruments of the indigenous inhabitants of North America by Helen H. Roberts. A contribution by Mr. William Morgan on "Human Wolves among the Navahos" will be found of considerable interest to students of European witchcraft and demonology. Not only do the Navaho beliefs relating to the werwolf bear a strong resemblance to certain of the European beliefs, but also the all-pervasive Navaho belief in witchcraft suggests something of the atmosphere in which the European witchcraft superstition and consequent persecutions became rife. Mr. George P. Murdock studies "Rank and Potlatch among the Haida", providing something of a rational setting for a custom which, as usually described, is beyond the range of normal reasoning, and thereby affording a valuable object lesson for the student of social anthropology. In this connexion, however, Prof. R. C. Thurnwald's account of the profane literature of Buin, Solomon Islands, is even a more valuable pointer towards a method of gauging social values, while affording an index of change under contact with external influences. The songs which he collected, at first in 1908–9 and then in 1934, deal with topics of everyday life, and by their difference in manner and matter show unconsciously but infallibly how times have changed.

Sodium Lamps for Lighting Tennis Courts

FOR the lighting of tennis courts it is essential that there should be complete freedom from glare and that the light should have a high speed of discrimination. In *Philips Technical Review* (Eindhoven) of August last, it is pointed out that both these requirements are exceptionally well fulfilled by a lighting system employing sodium lamps. Although no satisfactory method has yet been found for making quantitative measurements of the disturbing effect produced with different types of light, experience has shown that the presence of a source of light in the field of vision is less disturbing with sodium lamps than with other lamp sources of equivalent total candle power. This is due to the comparatively low luminous intensity of sodium lamps. Several experimenters have also proved that the speed of discriminating objects is quicker with sodium light than with other types of light. The illumination of tennis courts is particularly important in regions with a tropical climate where the heat renders play during the day impossible, and where during the evening, when the atmosphere is cooler, darkness sets in very quickly. Three open-air tennis courts in the Netherlands East Indies were recently equipped with sodium lamps. Good results have been obtained with an arrangement of eight 150 watt sodium lamps arranged in two rows, containing four each, on the sides of the court and situated 20 feet above the ground.

Phenology of 1935

THE Phenological Report for 1935 by I. D. Margary (*Quart. J. Met. Soc.*, 62, No. 265) covers the period December 1934–November 1935 inclusive. That period was of unusual interest on account of two spells of exceptional weather—the very wet December of 1934, and the bitterly cold period of May 1935 when a strong flow of air from polar regions brought severe frosts and snowstorms down even to the coastal regions of the south of England. The early months of 1935 were, on the whole, mild, with the result that in most counties flowers appeared early. The wintry weather in May therefore caused damage to plants and trees on a scale that luckily can probably be seen only once or twice in an average lifetime. Insects reacted eccentrically to this topsy-turvy weather that preceded the setting in of true summer weather, and showed very variable dates for their first appearance. Migrant birds behaved likewise; the species that normally arrive early were in the south mostly much in advance of their average first appearance; those that usually arrive late, for example, the garden warbler and the spotted flycatcher, were nearly all abnormally late. The spotted flycatcher was, however, exceptionally early in reaching the northern parts of Scotland and Ireland.

Soviet Arctic Exploration

IN continuance of its plans of Arctic exploration, the Soviet Government, according to the Soviet Union Year Book Press Service, is planning to dispatch ninety-five Arctic expeditions this year. Besides new geological prospecting work, topographical surveys in high latitudes will be combined with hydrographical work in the Kara and Laptev Seas. The northern rivers will also be studied with the view of improving transport. Research is also in hand on the problem of the northward extension of agriculture. Last year's work led to the discovery of coal deposits in the Chukchee peninsula, and these are now being worked.

New Coastline of Antarctica

THE Norwegian expedition to the Antarctic under Mr. L. Christensen which aims at mapping from the air the partially known coast-line of Antarctica between long. 100° W. and 10° E. is reported by *The Times* to have discovered one of the missing stretches of the coast. Mr. Wideroe, flying from the *Thorshavn*, found land between Queen Maud Land to the east and Princess Ragnhild Land to the west in about lat. 69° 30′ S. and long. 38° E. Even more interesting than this completion of the coast-line south of the Indian Ocean was the discovery by another flight of a mountain range extending westward for at least two hundred miles from lat. 71° 30′ S. and long 26° E., with peaks rising to 6,000 ft. and 10,000 ft. This range would appear to lie in Princess Ragnhild Land and to extend into the new land. Farther east, it may be remembered that in 1930 Sir Douglas Mawson found mountain ranges in the interior of Enderby Land. In all probability, these ranges will prove to be fault ranges along the edge of the plateau of the eastern Antarctic.

Presentation to Dr. E. J. Butler, F.R.S.

FOR many years, mycologists throughout the world have reaped the benefits of the great work carried out by Dr. E. J. Butler, the first director of the Imperial Mycological Institute, Kew. Following upon his resignation, workers in all parts of Australia contributed to a presentation fund organized by Dr. W. L. Waterhouse of the University of Sydney. Acting on their behalf, the High Commissioner for the Commonwealth in London, Mr. S. M. Bruce, kindly consented to make the presentation, which took place at the Institute on February 8 in the presence of the members of the staff, most of whom had been with Dr. Butler throughout his term of office. One of the gifts was an inscribed table clock made of Australian woods.

Biological Equipment

MESSRS. GRIFFIN AND TATLOCK, LTD., Kemble Street, Kingsway, London, W.C.2, have issued a catalogue, No. 30 *K*, of biological and general apparatus and laboratory equipment for bacteriology, pathology, public health, chemistry and cognate sciences. In addition to laboratory fittings, and the ordinary chemical and physical glass-ware and apparatus and reagents, microscopes by various makers, microtomes, incubators, and blood and milk testing instruments are included. An extensive series of anatomical diagrams and models, osteological preparations, and mounted microscopic objects are also listed. Practically all laboratory requirements appear in this catalogue, which is well produced and illustrated, and strongly bound.

Sir Warren Fisher, Permanent Secretary of H.M. Treasury since 1919; Prof. R. H. Fowler, Plummer professor of applied mathematics in the University of Cambridge since 1932; Dr. W. B. Yeats, author of poetic and dramatic works, have been elected members of the Athenæum under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service.

THE Council of the Institute of Metals has elected Dr. Harold Moore and Mr. W. Murray Morrison to the short list of fellows of the Institute, limited in number to twelve, who have "rendered eminent service to the Institute". Dr. Moore is a past-president of the Institute and director of the British Non-Ferrous Metals Research Association. Mr. W. Murray Morrison is an original member of the Institute, having assisted in its formation in 1908. He is vice-chairman and managing director of the British Aluminium Company, Ltd.

AT the annual general meeting of the Royal Astronomical Society, held on February 12, the following officers were elected: *President*, Dr. H. Spencer Jones; *Vice-Presidents*, Sir Frank Dyson, Prof. E. A. Milne, Prof. H. C. Plummer, and Prof. W. M. Smart; *Treasurer*, J. H. Reynolds; *Secretaries*, W. M. H. Greaves, and Prof. H. H. Plaskett; *Foreign Secretary*, Sir Arthur Eddington.

PROF. E. J. SALISBURY will deliver the Masters Memorial Lectures of the Royal Horticultural Society in the lecture room of the Society's New Hall in Greycoat Street, Westminster, on March 9 and March 23 at 3.30 p.m. The subject of the lectures will be "The Plant and its Water Supply".

MR. L. B. TANSLEY has been appointed assistant director of the Testing House and Laboratory of the Manchester Chamber of Commerce, Royal Exchange, Manchester. At present, Mr. Tansley is assistant to the Director of the British Cotton Industry Research Association.

THE second Conference on Industrial Physics arranged by the Institute of Physics will be held in Birmingham on March 18–20. The subject of the Conference will be "Optical Devices in Research and Industry". The president of the Institute, Prof. A. Fowler, will deliver his presidential address, entitled "Spectroscopy in Industry", on March 18. Further information can be obtained from the Secretary, Institute of Physics, 1 Lowther Gardens, Exhibition Road, South Kensington, S.W.7.

IN order to encourage original medical research, the Grocers' Company offers three scholarships, each of £300 a year, with an allowance to meet the cost of apparatus, tenable for one year but renewable for a second or third year. The next election will take place in May. Applications must be made before the end of April to the Clerk, Grocers' Hall, E.C.2, from whom further information can be obtained.

To commemorate the services of the late Sir Grafton Elliot Smith to University College, London, and to the advancement of anatomical and anthropological teaching and research, it is proposed that a bust of him should be modelled in bronze by Mr. A. H. Gerrard of the Slade School, and placed in the Thane Library of the College. Contributions towards the cost of the bust, made payable to "The Elliot Smith Memorial Fund", should be sent to Prof. J. P. Hill, University College, Gower Street, London, W.C.1.

THE Silver Jubilee Commemoration (1934) award of five guineas is granted annually by the Illuminating Engineering Society, which is open to members of the Society less than twenty-six years of age. The award may be made (1) for a suitable paper dealing with illuminating engineering, (2) the design or construction of a novel instrument or appliance for use in researches on illumination, or (3) the carrying out of any investigation beneficial to illuminating engineering. Further information can be obtained from the Secretary, Illuminating Engineering Society, 32 Victoria Street, London, S.W.1.

PROF. GEORGES BOULIGAND, professor of differential and integral calculus in the University of Poitiers, has been elected *correspondant* of the Section of Mechanics of the Paris Academy of Sciences in succession to the late Dr. Joseph Auclair.

PROF. HANS MOLISCH, vice-president of the Vienna Academy of Sciences, Dr. Julius Wagner-Jauregg, emeritus professor of psychiatry at Vienna, Dr. Hans Horst Meyer, emeritus professor of pharmacology at Vienna, Dr. Otto Loisi, professor of pharmacology at Graz, and Dr. Victor Hess, professor of experimental physics at Innsbrück, have been awarded the Austrian insignia for science and art.

A PHARMACOLOGICAL department is being organized in the Gorky Institute of Experimental Medicine at Moscow under the direction of Prof. Nikolayev to study the reactions of various medicines on the sick and healthy. Special attention will be paid to the effectiveness of traditional home remedies of various nationalities and of Eastern medicines in particular.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 332.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Cosmological Constants

THE fundamental constants of physics, such as c the velocity of light, h Planck's constant, e the charge and m mass of the electron, and so on, provide for us a set of absolute units for measurement of distance, time, mass, etc. There are, however, more of these constants than are necessary for this purpose, with the result that certain dimensionless numbers can be constructed from them. The significance of these numbers has excited much interest in recent times, and Eddington has set up a theory for calculating each of them purely deductively. Eddington's arguments are not always rigorous, and, while they give one the feeling that they are probably substantially correct in the case of the smaller numbers (the reciprocal fine-structure constant hc/e^2 and the ratio of the mass of the proton to that of the electron), the larger numbers, namely the ratio of the electric to the gravitational force between electron and proton, which is about 10^{39}, and the ratio of the mass of the universe to the mass of the proton, which is about 10^{78}, are so enormous as to make one think that some entirely different type of explanation is needed for them.

According to current cosmological theories, the universe had a beginning about 2×10^9 years ago, when all the spiral nebulæ were shot out from a small region of space, or perhaps from a point. If we express this time, 2×10^9 years, in units provided by the atomic constants, say the unit e^2/mc^3, we obtain a number about 10^{39}. This suggests that the above-mentioned large numbers are to be regarded, not as constants, but as simple functions of our present epoch, expressed in atomic units. We may take it as a general principle that all large numbers of the order 10^{39}, 10^{78} . . . turning up in general physical theory are, apart from simple numerical coefficients, just equal to t, t^2 . . . , where t is the present epoch expressed in atomic units. The simple numerical coefficients occurring here should be determinable theoretically when we have a comprehensive theory of cosmology and atomicity. In this way we avoid the need of a theory to determine numbers of the order 10^{39}.

Let us examine some of the elementary consequences of our general principle. In the first place, we see that the number of protons and neutrons in the universe must be increasing proportionally to t^2. Present-day physics, both theoretically and experimentally, provides no evidence in favour of such an increase, but is much too imperfect to be able to assert that such an increase cannot occur, as it is so small; so there is no need to condemn our theory on this account. Whether the increase is a general property of matter or occurs only in the interior of stars is a subject for future speculation.

A second consequence of our principle is that, if we adopt a scheme of units determined by atomic constants, the gravitational 'constant' must decrease with time, proportionally to t^{-1}. Let us define the gravitational power of a piece of matter to be its mass multiplied by the gravitational constant. We then have that the gravitational power of the universe, and presumably of each spiral nebula, is increasing proportionally to t. This is to some extent equivalent to Milne's cosmology[1], in which the mass remains constant and the gravitational constant increases proportionally to t. Following Milne, we may introduce a new time variable, $\tau = \log t$, and arrange for the laws of mechanics to take their usual form referred to this new time.

To understand the present theory from the point of view of general relativity, we must suppose the element of distance defined by $ds^2 = g_{\mu\nu} dx_\mu dx_\nu$ in the Riemannian geometry to be, not the same as the element of distance in terms of atomic units, but to differ from this by a certain factor. (The former corresponds to Milne's $d\tau$ and the latter to Milne's dt.) This factor must be a scalar function of position, and its gradient must determine the direction of average motion of the matter at any point.

P. A. M. DIRAC.

St. John's College,
Cambridge.

Gamma Rays excited by Capture of Neutrons

LEA's observations and Fermi's pioneer work has shown that many elements may capture a neutron, and emit gamma rays in the process. This phenomenon has been further investigated especially by Rasetti[1], and more recently by Kikuchi[2] and Fleischmann[3], who used polonium-beryllium, deuteron-deuterium and radon-beryllium sources respectively.

We have used radon-beryllium sources, with an experimental arrangement designed to reduce the high background effects of the Geiger counter due to the gamma rays emitted by this type of neutron source, and also to concentrate slow neutrons on the counter. As indicated in the diagram (Fig. 1), a cylindrical block of lead 18 cm. in diameter and 44 cm. in length is sunk into a thick-walled paraffin wax tube closed at the bottom. The radon-beryllium neutron source is placed on the axis of the lead block at a distance of 29 cm. from the top. The neutrons emitted are slowed down by the paraffin wax, diffuse through the lead core, and slow neutrons emerge at the top of the lead block. The efficiency of this arrangement is based on the fact that the mean free path for scattering of slow neutrons is much larger in lead than in paraffin. Gamma ray effects were measured by a thin-walled magnesium counter covered by a thick-walled lead tube and placed in the neutron stream; beta rays and secondary electrons were measured with the same counter uncovered.

The capture radiation from a thick sheet of cadmium (0·4 gm./cm.^{2}) placed below the counter produced 1,700 impulses per minute above the background; the background amounted to 440 impulses per minute with a radon-beryllium source of about 500 mc. The capture radiation of cadmium (and other strongly absorbing elements) is thus a sensitive, and in many respects a very convenient, indicator for slow neutron intensities in our arrangement.

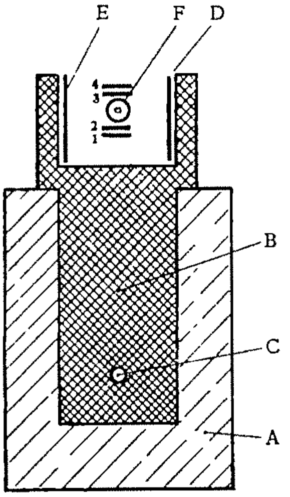

Fig. 1.

A, PARAFFIN WAX TUBE; *B*, LEAD CORE; *C*, RADON-BERYLLIUM SOURCE; *D* AND *E*, BORON SCREENS; *F*, GEIGER-MÜLLER COUNTER, 1, 2, 3, 4, POSITIONS OF THE SAMPLES.

We have used it as an indicator to determine the absorption of slow neutrons in a number of elements. A sample of the element was placed below the counter, a sheet of cadmium inserted between this sample and the counter, and the gamma ray effect measured. This, compared with the gamma ray effects obtained in the absence of the cadmium, and in the absence of the sample, gives the absorption of the sample. The results are shown in Table 1. Our values are not corrected for a slight divergence of the neutron stream, which may account for the fact that most of them are slightly above those of Dunning and Pegram[4], who used the disintegration of lithium as an indicator.

TABLE 1.

Element	Compound	gm./cm.^{2}	Per cent transmitted	Cross-section ($\times 10^{-24}$ cm.^{2})
Cl	CCl_4	1·30	34	52
Co	Co_2O_3	2·87	44	39
Rh	Rh	0·68	51	170
Ag	Ag	1·07	56	97
Cd	Cd	0·0285	50	4,500
Ir	Ir	0·61	46	410
Au	Au	3·14	37	103
Hg	HgO	0·70	50	355

Further, we have compared the gamma ray effect per captured neutron as measured by the counter for a number of strong absorbers of slow neutrons, and the results are given in Table 2. The value for cadmium is arbitrarily fixed at 100.

TABLE 2

Cl	Co	Rh	Ag	Cd	In	Sm	Gd	Ir	Au	Hg
95	86	82	75	100	94	94	94	74	80	105

The same samples of elements were used to measure both the absorption cross-section and the gamma ray effect, and the values given in column four of Table 1 were then used to compute the relative gamma ray effect per captured neutron. The value for indium includes gamma rays from the induced activity of the 54-minute period. Otherwise the figures include only gamma rays from induced activities of periods shorter than half-hour; longer periods were not appreciably excited in our experiments.

The eleven elements investigated give almost equal effects although their atomic weights range from 35 to 200.

A similar comparison of the gamma rays emitted by elements which are weak absorbers of slow neutrons would, in our opinion, require better data on the elastic scattering of such elements than is at present available. So far, with no element heavier than chlorine have we found evidence to show that the gamma ray effect is appreciably different from 'normal'.

About equal effects might be expected if each element emitted one gamma ray quantum per captured neutron, but other observations do not support this simple interpretation of our result, since they seem to indicate that a larger number of quanta are emitted from the investigated elements.

We obtained some indication of this number by comparing the number of fast electrons ejected backwards from lead by the gamma rays from cadmium which were excited by a slow neutron beam, with the number of beta rays from a very thin silver foil made radioactive by the same neutron beam. Half-value thicknesses in lead were determined for the electrons from lead and for the gamma rays from cadmium. The values obtained indicate that more than seven quanta are emitted from cadmium per captured neutron, but this result requires confirmation by an independent method which is now being attempted.

The fact that chlorine shows a 'normal' gamma ray value indicates that its intense neutron absorption is due to radiative capture that leads to a chlorine isotope of long half-life period which has not yet been detected. Samples of yttrium prepared free from gadolinium by Dr. J. K. Marsh, Old Chemistry Laboratory, Oxford, showed only very weak capture radiation and, in agreement with a measurement of Hevesy[5], a small absorbing cross-section. Thus the widespread view[6], based on earlier measurements, that yttrium has a large capture cross-section for slow neutrons and therefore must transform into an undetected radioactive isotope, does not seem to be justified. Barium also shows a much smaller capture cross-section ($< 10 \times 10^{-24}$ cm.^{2}) than given by earlier measurements[4]. In agreement with Kikuchi[2], we find that boron shows a gamma ray effect of about a twentieth of that of cadmium.

Resonance Levels of Neutrons in Silver Nuclei

THE resonance absorption of neutrons by silver nuclei has been studied with a photo-neutron source by Kurtschatow and Schepkin[1] and by us[2]. Continuing this work, we have now estimated the total width of the resonance levels effective for neutron capture which have their energy values lying in the continuous spectrum of the neutrons scattered in a thin paraffin layer. Using the formula of Breit and Wigner[3] for the capture cross-section as a function of energy, and making some simplifying assumptions, we can evaluate the average spacing between adjacent levels in the energy region concerned, by giving a plausible value to the width of a single level.

In our experiment, the neutron source consists of 50 mgm. of radium surrounded with 12 gm. of beryllium powder. It gives $1 \cdot 0 \times 10^4$ neutrons per second, as deduced from the work of Chadwick and Goldhaber[4]. In order to produce a continuous spectrum of neutrons, the source is surrounded with a spherical paraffin shell of 0·5 cm. thickness. Two silver detectors of 0·4 mm. thickness are used. Each is screened with cadmium, and subtends a solid angle 0·71 at the source during exposure. According to a formula of Wigner[5], the neutron-proton scattering cross-section is 11×10^{-24} cm.^{2} for neutrons of 2×10^5 volts. The total number of scattered neutrons received by the detectors is then 450 per second. By means of a Geiger-Muller counter, the number of β-rays emerging from the surfaces of the silver detectors in the saturation state is found to be 1·4 per second for the activity of half-period 22 sec. We had measured also the apparent absorption coefficient of the resonance neutrons in a thin silver absorber of 0·020 gm./cm.^{2} and get the value $12 \cdot 5 \times 10^{-22}$ cm.^{2} per silver nucleus. For the absorption coefficient of the β-rays emitted from silver, we find 10×10^{-22} cm.^{2} per silver atom.

Let us assume that the photo-neutrons consist of one homogeneous group of energy $E_0 = 2 \times 10^5$ e.v.; let n_1 be the density of the effective resonance levels per volt and 2Γ be their half-value width, assumed to be equal for all levels. Then it can be shown by a calculation which will appear elsewhere that the total half-value width summed over the effective resonance levels from zero to 2×10^5 e.v. can be evaluated from our experimental results. We find $2\Gamma n_1 E_0 = 520$ e.v. If Γ be given the value 0·1-1·0 volt[6], the average spacing between adjacent effective resonance levels is then of the order 80–800 volts. This result is in good accord with a recent theoretical estimate given by Bethe[7], namely, of the order 50–500 volts. It is also in conformity with the frequency of occurrence of the resonance groups in the low energy region.

Details of this work will be published in the *Chinese Journal of Physics*.

A New Phenomenon in the Supraconducting Transition of Tantalum and of Tin

THE transition from the supraconducting to the normal resisting state under certain conditions is found not to be continuous but to include a hitherto unsuspected spontaneous increase in resistance followed by a slower decrease. The spontaneous decrease in resistance usually proceeds for several minutes in a succession of steps, until only a fraction of its crest value remains. This crest value of the transient resistance is sometimes 75 per cent of the normal. After such an effect has occurred, it will not occur again when the same conditions are re-established, unless in the meantime the temperature has been lowered or else a time interval of at least half an hour has elapsed.

These spontaneous changes in resistance can be initiated by a step upward in temperature, in current or in magnetic field, and proceed thereafter as described above while all three external conditions are maintained constant. The combination of temperature, field and current at which this phenomenon appears has been studied and the progress of the resistance change under various conditions noted. The effect is pronounced only when the current is relatively large (about 2 amperes in the tin wire, diameter 0·022 cm.).

A more complete report of this work will appear in the March issue of the *Journal of Research of the National Bureau of Standards*.

Influence of Magnetic Fields on Persistent Currents in Supraconducting Single Crystals of Tin

UP to the present, the determination of the effect of a magnetic field in restoring the resistance in a metal conductor which is in the supraconducting state has depended on the direct measurement of the resistance of the conductor, and consequently it has been difficult to find the exact point at which the first traces of resistance return.

In the McLennan Laboratory at Toronto there have been in use supraconducting galvanometers[1] by means of which it is possible to measure directly, under various conditions, the value of the persistent current in a completely supraconducting circuit. With such an instrument, it is easy to find the magnetic field under which resistance begins to appear, for the smallest resistance causes rapid cessation of the persistent current. These measurements have been carried out for a cylindrical single crystal of tin, in both transverse and longitudinal external fields, at a temperature of 3·22° K. (0·5° below the normal transition point).

According to the theory of von Laue[2], F. London[3], and R. Peierls[4], the penetration of a transverse magnetic field into a cylindrical supraconductor should commence when the external field has reached one half of the critical field strength, H_c, and the body should then pass into the so-called 'intermediate state', and show resistance. In a longitudinal field, the resistance should return abruptly when the external field is equal to H_c.

In Fig. 1 the observed persistent current is plotted against the external magnetic field, in Curve I for transverse fields, and in Curve II for longitudinal fields. With a transverse magnetic field, no persistent current flows in a field greater than 41 gauss, while with a longitudinal field the limiting value is 71 gauss. The ratio of the transverse to the longitudinal field for the first appearance of resistance is therefore 0·58 instead of 1/2. This result agrees with the work of de Haas, Voogt and Jonker[5], who also found this ratio to be 0·58 in the case of direct resistance measurements. Along the descending portion *AB* of Curve I, the persistent current decreases as the external field is increased, in such a way that the relation $\frac{H}{0{\cdot}58} + H_i = H_0$ is obeyed, where $H_i = \frac{2i}{r}$ is the field at the surface of the wire due to the current itself.

The Sterckfontein Ape

The letter from Dr. E. Schwarz which appeared in Nature of December 5 shows, I think, the necessity for some hesitation before coming to any definite conclusion as to the affinities of *Australopithecus*. Dr. Schwarz considers it "very probable that *Australopitheous* was a pigmy gorilla"; and he has compared it with the dwarf chimpanzee of the Congo (*Pan satyrus panicus*). It is unnecessary at this stage to criticize in detail Dr. Schwarz's views, but the fact that other prominent anatomists have come to quite different opinions shows that we are not yet able finally to place it.

Dr. Adloff, who has made a special study of the dentition of *Australopithecus*, says, "Das Gebiss von *Australopithecus* ist aber rein menschlich und lässt den Schluss zu, dass *Australopithecus* kein Anthropoide, sondern ein Hominide ist". Dr. Gregory, of New York, who is probably the greatest living authority on mammalian teeth, has pointed out that of twenty-six dental characters in *Australopithecus*, not one is nearer to the chimpanzee, two are nearer to the gorilla, one is nearer to the chimpanzee and gorilla, three are common to the chimpanzee, gorilla and primitive man, and twenty are transitional to or nearer to primitive man; and he adds: "if *Australopithecus* is not literally a missing link between the older dryopithecoid group and primitive man, what conceivable combination of ape and human characters would ever be admitted as such?" Romer, of Harvard, the eminent American palæontologist who made a careful study of the Taungs ape in 1929, while not definitely deciding as to the affinities, says it is "clearly not a chimpanzee or a gorilla".

All this seems to show that *Australopithecus* is a form of considerable interest whose affinities are difficult to determine; but I think it likely that the whole question will be quite definitely settled within two years. In the meantime, I may mention that the brain of the Sterckfontein ape was considerably smaller than was at first believed. The contact of the occipital fragment has been found, and the restored brain appears to have been only about 435 c.c. It is thus an ape fairly comparable in size with the chimpanzee, but with teeth which in my opinion resemble those of man much more than they do those of any of the living anthropoids.

Vitamin P

We reported in our previous notes[1] on the vitamin nature of phenyl-benzo-γ-pyrone dyes, and have described a method for the experimental demonstration of this activity. Using this method, we tested the following substances for their vitamin activity: hesperidine (m.p. 261°), an impure sample of demethylo-hesperidine (mother liquor of 'citrin') and quercitrine, 1 mgm. being given daily.

The experiment consisted of seven groups of 20 guinea pigs each. One of these groups received the basal diet only. The other groups received in addition: hesperidine, demethylo-hesperidine, quercitrine, ascorbic acid (2 mgm.), ascorbic acid plus hesperidine, ascorbic acid plus demethylo-hesperidine.

All three groups receiving ascorbic acid equally showed normal growth. The animals receiving hesperidine, or demethylo-hesperidine only, behaved in the same way as the animals of our previous experiments receiving 'citrin'. The animals receiving the basal diet only or this diet and quercitrine showed severe scurvy and died after a sharp fall in weight on about the twenty-eighth day.

These results admit of the following conclusions: experimental scurvy, as commonly known, is the symptom of a mixed C and P avitaminosis. Pure C avitaminosis can be observed, if in addition to the basal diet vitamin P is administered. The pure P avitaminosis has no clinical symptoms. If, however, vitamins C and P are simultaneously withheld, the lack of P will greatly modify the pathological condition.

There is a great difference in the activity of different phenyl-benzo-γ-pyrones. Since the only essential difference in the formula of quercitrine and hesperidine is found on the C^2 and C^3 atoms, it can be concluded that these atoms are of special importance for the activity. Changing the flavanone hesperidine into the corresponding flavonole entails inactivation.

The therapeutic effects observed after the administration of 'citrin' in man in septic conditions, also accompanied by polyarthritis and endocarditis, suggest that the age-old beneficial effect of fruit juice is partly due to its vitamin P content.

Plant Collecting on the Pribilof and Aleutian Islands, 1936

THE Aleutian Islands stretch from the tip of the Kenai Peninsula of Alaska for 1,200 miles westwards to Kamchatka. They comprise some fifteen larger islands and hundreds of smaller ones, and owing to their inaccessibility have been very little explored botanically.

The Swedish botanist of Kamchatka, Dr. Erik Hulten, of the University of Lund, made important observations on the Aleutian isles in 1932. I visited them last summer, through the courtesy of the United States Government (to which they belong), and was also allowed to spend some days and make a botanical collection for the British Museum (Natural History) on the prohibited fur-seal islands of the Pribilofs, about 150 miles north of the Aleutians.

Unalaska village, near Dutch Harbour, was my base for botanical work in the Aleutians. I reached it from Seward, in Alaska, in mid-July by a small monthly steamer, the *Starr*. Owing to delay *en route* I was able to spend some time collecting at Seward, and two weeks on the very interesting and fertile island of Kodiak, off the Kenai Peninsula. During the eruption of Katmai in 1913, the north-east portion of Kodiak lay for long under a thick covering of ash which killed all vegetation for a year or two.

At Unalaska I collected during part of July and early August, and made a collection of about 318 specimens. The island is very fertile, vegetation growing up to the summits of many of the mountains of several thousand feet, but owing to the dense vegetation and entire lack of roads it is very difficult in summer to get far afield, as there is no means of transport. Finding the further islands quite inaccessible without the aid of the United States coastguard vessels (which were in 1936 the only ones calling there once or occasionally twice in the season), I applied to the Department of the Interior at Washington, and was granted permission to make the last trip of the season, in August (unfortunately late for botanical work) so far west as Attu, the last of the islands, on the United States Coastguard Cutter *Chelan*, which was doing hydrographic survey work in these uncharted waters. Unfortunately, landings were usually brief, but on Attu (where a precarious landing of a few hours was all that was possible owing to bad weather conditions) I was granted the help of two sailors of the *Chelan* in collecting the plants, and obtained some seventy specimens, including a few Asiatic species not gathered on the other islands. Landings of two days were made at Kiska (where some fifty to sixty species were gathered), an interesting volcanic island, now a prohibited shore to aliens as it is a U.S. naval reserve, and at Amchitka and Atka.

In all, some 2,000 specimens were gathered on the Kenai Peninsula and the Aleutians, including about 160 species from the Pribilof Islands. Many thanks are due to the personnel of the U.S.S. *Chelan* and the coastguard authorities at Unalaska for their kind assistance, and to the agent of the U.S. Government and the Bureau of Fisheries on the Pribilof Isles, for much valuable assistance in transport and collecting.

An Amphipod, *Eucrangonyx gracilis* S. I. Smith, new to Britain

RECENT exhaustive investigations into the fauna of filtration plants, which are being conducted by the Water Examination Department of the Metropolitan Water Board, under the direction of Colonel C. H. H. Harold, have resulted in the discovery at the Lea Bridge Waterworks of *Eucrangonyx gracilis* S. I. Smith.[1] This species has been recorded only from Canada and the United States. It was collected in October and November 1936 by Mr. A. C. Gardiner, from whom I obtained the following notes on its distribution in the filters and its appearance in life. Specimens were submitted for identification to Prof. A. Schellenberg, of Berlin, to whom my thanks are due.

The majority of specimens were found in culverts below the filter beds at the Lea Bridge Works : these culverts are in complete darkness, and specimens from them were whitish in colour, though with well-developed black eyes. A few were found among weeds on the grating of the intake to these filters, together with *Asellus aquaticus* (which was also found in the subterranean culverts) and *Gammarus pulex*. These specimens were of a quite dark slaty-blue colour. It was not ascertained whether this species was present in the River Lea, from which these filter beds are supplied with water. It is even possible that it is widely distributed in England. In Canada and the United States it has been recorded from a large number of loci, chiefly in surface waters. A list of these can be found in Shoemaker[1].

Eucrangonyx can be distinguished from *Gammarus* by the absence of spines on the dorsal surface of the urosome : from *Niphargus* by the presence of well-developed black eyes and from *Crangonyx* by the presence of a small inner ramus to uropod III. *E. gracilis* can usually be distinguished in life from *Gammarus pulex* by its smaller size. Stebbing[2] gives a detailed description of this species. The only published figure of the whole animal is that of Kunkel[3], which is crude and in some respects incorrect. Various features are figured by Weckel[4], Huntsman[5] and Shoemaker[1]. Weckel's figures are inferior to those of Huntsman and Shoemaker.

Origin of Cross-Cousin Marriage in Assam

CROSS-COUSIN marriage is widely prevalent among the primitive peoples of Assam. Of the two types, the marriage with the daughter of the mother's brother is more frequent. Different theories have been put forward by ethnologists as to the origin of this custom, but none of them seems to be tenable in Assam area.

Though most of the tribes of Assam are now patrilineal, yet an earlier stratum of matriliny should not be overlooked. Even among some of the tribes, matrilineal traits are still dominant. These matrilineal people probably came in contact with later patrilineal immigrants of superior culture, and marriages between them were frequent. During this period, the immigrant people, in order to give their sister's family better economic status, introduced the marriage of their sister's son to their own daughters. The contact in some cases led to the formation of dual groups, and there both types of cross-cousin marriage were permitted. But after a time, when the domination of the patrilineal people was complete, the avoidance of the father's sister's daughter came from the idea that father and father's sister inherited the same blood, so her daughter, who also inherited a part of the blood through her mother, was not marriageable. This idea is still common among the Chothe Kukis, Mantak Koms and other tribes of Assam. In some cases, the patrilineal dominance is so strong that, in the absence of the mother's brother, the bride-price accrues to his son, that is, the mother's brother's son will get the payment for his father's sister's daughter, as is found among the Chothes.

This rule, on the face of it, seems to be absurd, but if we go into details we can easily understand the underlying principle. In the early matrilineal stage referred to, the marriage between the children of brothers and sisters was not looked upon with favour by the earliest group as it would break the 'household exogamy'. But the later group would not observe this rule, as it would be against their interest, and they might have no reason for observing 'household exogamy'. The husband in such a group, finding property to descend matrilineally, would try to provide for his portionless sister's family by marrying his sister's son to his daughter. The wife who owns the property and observes the rules of the earlier people would not object as 'household exogamy' on her side of the family would not be violated. In this way marriage with the daughter of the mother's brother would come into vogue. But she would be opposed to her children marrying her own brother's children. Hence the other cross-cousin marriage (father's sister's daughter) would not be permissible. In some cases also, marriage with the daughter of the mother's brother would not be allowable. But if the three groups (two older and the one later) were linked up in a tri-clan system, this problem would disappear.

If later on, through the dominance of the patrilineal people of this group or other groups, the whole social and economic structure passes on to father-right, only the tradition of such preferential mating, with occasional actual marriages, would persist. This seems to be the present position in Assam.

Annual Variation of the Critical Frequencies of the E- and F_2-Layers

THE successive accumulation of data on the critical frequencies, that is, the limiting penetrating frequencies, of the E- and F-layers determined from noon observations show the following main features[1]: the critical frequencies of the E-layer show a regular annual variation depending on the height of the sun, whereas the critical frequencies of the F_2-layer show an inverse annual variation, with high values during winter and lower values in summer. Appleton[2] has explained this as a temperature effect, the density of the air at 200–400 km. in winter being higher on account of the lower temperature. According to the simple theory of photo-ionization, the maximum electron density, that is, the critical frequency, will depend on the pressure.

From a geophysical point of view, it is difficult to understand why an annual temperature variation should be restricted to the F_2-layer alone. Studies of the variation of the auroral heights in the border region between the dark and sunlit atmosphere have shown[3] that there is a marked diurnal variation of temperature at a height of 100 km., that is, in the region of the E-layer. It is therefore probable that the annual variation of temperature in the F_2-layer also must include the E-layer.

A hypothesis explaining the dependence of the critical frequencies of the F_2-layer on, and the independence of the critical frequencies of the E-layer of, the annual temperature (and therefore, pressure) variations will be put forward in the following, based on noon observations of the critical frequencies recorded at Tromsø ($\varphi = 69 \cdot 7°$ N., $\lambda = 18 \cdot 9°$ E.) during the last two years.

The observations from Tromsø show the same inverse annual variation of the critical frequencies of the F_2-layer with high values in winter and low values in summer previously observed. During the dark period in winter, when the sun's height at noon is negative, the sun's rays when producing the dense F_2-ionization in the zenith have to enter the layer from below after first having passed once through the layer. During the same period one does not obtain E-echoes on undisturbed days. This means that the part of the solar spectrum producing the F_2-ionization is only slightly absorbed when passing through the F_2-layer, whereas the rays producing the E-ionization are completely absorbed when entering the E-layer. From this it follows that a variation in the pressure of the air in the F_2-layer will strongly influence the ion-production of the rays, as the spectral energy producing the ionization is in excess. For the E-layer, where the ionizing rays are completely absorbed when entering the layer, a variation of pressure (and therefore temperature) will be of minor importance, as the maximum ionization there will be determined by the limited energy of the ionizing rays.

Chapman[4] has developed a theory according to which there is a stratification in the ionosphere; at heights above 200 km. the oxygen molecules are dissociated and occur as atomic oxygen. There will therefore be different parts of the solar spectrum which produce the ionization in different levels, according to the different ionization potentials of the constituents. The ionization potentials of N_2, O_2 and O correspond to the bands from 766 A., 730 A. and 910 A., and according to Chapman[5] the energy available in the solar spectrum from 910 A.

for ionizing the oxygen atoms is more than a hundred times greater than the energy available for ionizing O_2 and N_2. This fits in with the point of view developed above that the energy of the part of the solar spectrum producing the F_2-ionization is in excess when passing through the layer.

Excitation of Raman Spectra with the aid of 'Optical Catalysers'

PROSAD and Bhattacharya have reported[1] the 'optical catalysis' of the Raman effect. That this phenomenon should exist is in accordance with the theory of the Raman effect along classical lines which we have presented elsewhere[2]. Moreover, it is possible from that theory to predict the circumstances in which the catalysis should be most pronounced.

According to this theory, the emission of the Raman lines is facilitated by the close proximity of a system resonant at the frequency of the difference line or anti-resonant at that of the sum line. It is hindered by the reverse of these conditions. If the observed effect is due to such a resonance in the 'catalyser', we should expect the following experimental results: (1) The effectiveness of a particular 'catalyser' should vary with the frequency of the incident light, being a maximum for some one frequency. (2) Two substances having different infra-red frequencies should be 'catalysed' by the same added substance, provided the incident frequencies are so adjusted as to make the difference, or sum, frequencies the same for both. (3) It should be possible to find substances the addition of which reduces the Raman effect. In particular, if the effect of a 'catalyser' is found to show a maximum for a particular incident frequency, a shift of the incident frequency, such that the new sum frequency coincides with the old difference, should reduce the effect below normal.

The above considerations apply particularly to experiments at low temperatures, and the effects described might easily be masked at higher temperatures.

Fluorescence of the Bivalent Rare Earths

IN a letter in NATURE of January 19, 1935[1], I stated that the blue fluorescence shown by fluorites is due to bivalent europium produced through reduction of traces of trivalent europium by radium rays. In the same way a yellow-green band shown by some fluorites at low temperatures can be ascribed to bivalent ytterbium. Later[2], it was shown that a red fluorescence band that had puzzled us a good deal is due to bivalent samarium.

From the investigations of G. Jantsch and W. Klemm[3], it appears that these three rare earths, europium, ytterbium and samarium, are the only ones that can be obtained definitely as bivalent ions; whilst for thulium there are at least distinct indications of the formation of traces of bivalent compounds, for the other rare earths there are scarcely any. Taking the hypothetical connexion between the formation of bivalent ions and the appearance of radio-photo-fluorescence bands as a guiding hypothesis, one might hope to get such a fluorescence also with suitable substances containing traces of thulium.

Through the courtesy of Dr. P. Hoernes, I got from the Degea (Auergesellschaft) in Berlin a sample said to contain 93 per cent Tu_2O_3, 3 per cent Yb_2O_3 and 4 per cent Cp_2O_3, for which my best thanks are due. A small amount of this substance was added to calcium sulphate (concentration 10^{-3}). After exposure to radium rays, the preparation was tested with filtered ultra-violet light. At room temperature, nothing was observed, but on lowering the temperature a red fluorescence appeared that became very brilliant at the temperature of liquid air. Calcium sulphate preparations with 10^{-3} erbium or 10^{-3} ytterbium, the neighbouring elements, showed under the same conditions a much weaker fluorescence, evidently due to inevitable traces of thulium. The maximum of the thulium band has nearly the same wavelength as that of samarium in calcium sulphate, about 620 mμ, but it is—at the same temperature—distinctly narrower and reacts quite differently towards changes of temperature, increasing in brightness with decreasing temperature, whilst the samarium band gradually disappears on nearing liquid air temperature. At the latter, the thulium band shows a structure which needs further investigation.

I have to thank Miss E. Rona for preparing the synthetic material, and Miss B. Karlik for photographing the spectra. A detailed report will be presented to the Vienna Academy of Sciences.

Claims of Geology in School Courses of General Science

PROF. TRUEMAN's letter in NATURE of February 6, as to the parlous state of geology in relation to teaching in schools, leads one to inquire further into the causes of this state of things.

Considering first the cultural aspect of the question, it is abundantly clear that the purely cultural value of geology is insufficiently realized by teachers in secondary schools. This is all the more puzzling in view of the rapid hold which it exercises on the imagination when properly taught, and the extreme value of its field side to adolescents.

My experience during the last twenty years has led to the conclusion that geologists lost a valuable chance of introducing their subject into schools when they allowed geographers to seize a branch (physical geology) in the great expansion which took place in geographical studies just after the Great War.

Turning to the utilitarian side of the problem, it is found that apart from mining and oil geology, geologists as a body are little interested in applications of their science, in this respect forming a marked contrast to chemists and physicists. At the present time, the posts open to graduates in geology fall roughly into four main classes: (1) appointments with mining and oil companies; (2) geological survey posts; (3) museum posts; (4) university appointments; and it is clear that the numbers and prospects of such posts are not such as to attract an increasing number of graduates in the near future One of the chief factors militating against a change in this position is the present overweening importance attached in most quarters to the purely stratigraphical side of the science, to the exclusion of a linking up with other sciences such as chemistry, physics and engineering.

I think it is correct to state that there is not a single trained full-time geologist on the staffs of Government departments, such as the Road Research and Building Research Laboratories, and I find it difficult to believe that there is not an outlet or opportunity for a suitably trained geologist in work of that kind. I have found that the possible applications of the science in civil engineering and building problems are many, but that men who are suited to the study of these problems are not being produced by our schools of geology to-day.

Application of the Polarographic Effect of Proteins in Cancer Diagnosis

THE investigations of E. Waldschmidt-Leitz[1] have shown that blood serum, similarly to blood itself[2], activates deactivated papain. Prof. E. Waldschmidt-Leitz[1] has also shown that normal blood serum induces in these ferments or in methylglyoxalase a greater activity than serum from carcinomatic blood. This activity is ascribed to the sulphydryl groups of the proteins of serum.

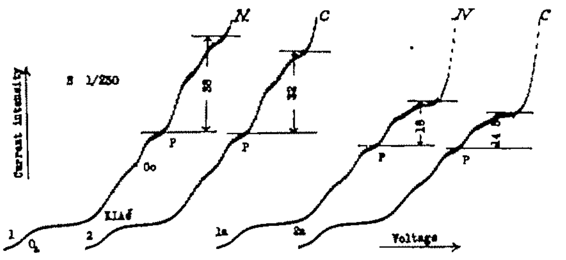

Fig 1.

CURVE 1, NORMAL SERUM, 'WAVE' *P* 38 MM. HIGH. CURVE 2, CARCINOMATIC SERUM, 'WAVE' *P* 32 MM. HIGH. BOTH SERA WERE TREATED WITH ALKALINE IODOACETATE FOR 70 MIN. CURVES 1*a* AND 2*a* WERE OBTAINED WITH THE SAME SERA AFTER 250 MIN. TREATMENT.

Some years ago, I found a sensitive polarographic protein effect, conspicuously exhibited by serum, which I explained as due to the catalytic activity of the sulphydryl groups of proteins[3]. It seemed thus important to investigate the differences between carcinomatic and normal sera polarographically, by electrolysis with the dropping mercury cathode. In this way a method has been worked out, in which the sulphydryl groups of serum proteins are acted upon by iodoacetate in alkaline solution, and after a certain time the denatured serum is subjected to the polarographic investigation. In these experiments, 0·3 c c. of serum, 0·15 c.c. of N potassium hydroxide and 0·3 c c of 0·2 N potassium mono-iodoacetate are mixed and kept at room temperature; after a certain time (about one hour) 0·1 c.c. is taken out and added to 5 c.c. of a solution consisting of 8×10^{-4} M cobalt chloride, 10^{-1} N ammonium chloride, 10^{-1} N ammonia. The polarographic curve of this solution is then recorded. The 'protein effect', consisting in the appearance of a characteristic 'wave' on the current voltage curve, is always found larger with normal serum than if in the same procedure carcinomatic serum is used (Fig. 1. Curves 1 and 2).

Another way which also leads to polarographic differences between carcinomatic and normal serum is to mix 0·3 c.c. of serum, 0·3 c.c. of water and 0·15 c.c. of N potassium hydroxide. After 5, 10 or 20 min., 0·1 c.c. of this mixture is added to 20 c.c. of the above cobalt solution, to be investigated polarographically. 67 different samples of various individuals were thus examined without knowledge of the clinical (histological) investigations, which were carried out by Prof. H. Knaus. 32 of these gave an abnormally low polarographic protein effect, and thus were reported as carcinomatic, in perfect agreement with the results of the medical examination and with the biochemical examination of Prof. Waldschmidt-Leitz.

Whilst the details of this investigation will be found elsewhere[4], it is mentioned here that the polarograms were obtained with Prof. J. Heyrovský's authentic polarograph, made by Messrs. Dr. V. and J. Nojedlý, Prague. A simple 'micropolarograph' suitable for medical routine work of this sort of research is under construction.

Time Lag in the Vacuum Photo-Cell

IN a recent letter[1] Dr. R. A. Houstoun treats equally as vacuum photo-cells the *KMV*6 and the *KV*6, both of which are made in these laboratories. The *KMV*6 is highly evacuated, but the *KV*6 always contains an appreciable quantity of hydrogen evolved from the sensitized potassium; it should not be regarded as a true vacuum cell.

No experiments made in these laboratories throw any light on the question whether the difference between the two cells discovered by Dr. Houstoun is actually due to this difference in gas content. My object is merely to point out that this possibility should not be excluded from consideration.

Genetics in Madrid

DURING a recent visit to Madrid for another purpose, I was able to visit some of my colleagues there, and was delighted to find that research work in genetics was continuing. Prof. I. de Zulueta, in the intervals of hiding the more precious contents of the biological museum in cellars, was continuing his work on the polymorphic beetle *Phytodecta variabilis*. Prof. Galan, of Salamanca, was very appropriately breeding the 'explosive cucumber', *Ecballium elaterium*. This plant is hermaphrodite in one half of Spain, diœcious in the other. Crosses between a diœcious plant and hermaphrodites from different areas seemed to reveal the existence of 'strong' and 'weak' local races, differing, like those of *Lymantria*, in respect of sex-determining factors.

Our discussion of these topics was interrupted by an air raid considerably more severe than any of those on London in 1914–18. However, no bombs fell very near us, and at the time I left, the Museo de Ciencias had not yet shared the fate of the University City, the Prado and the Museum of Anthropology. I think that the persistence of de Zulueta and Galan under conditions which are, to say the least, uncongenial for research, deserves to be recorded, and augurs well for the future of biology in Spain.

Neutrino Theory of Light

PROF. V. FOCK[1] has stated recently in these columns that he has found that the photon operator defined in the Jordan neutrino theory of light is commutable with its conjugate, and has thus claimed an inconsistency in the theory. It may be remarked that Fock's arguments in this connexion are not quite clear. Indeed, if we follow the notation in his note, we get:

$$\sqrt{|\nu\nu'|}\,(b_\nu b_{\nu'} - b_{\nu'} b_\nu) = \int_{-\infty}^{\infty} (\gamma_\alpha{}^\dagger \gamma_{\alpha+\nu+\nu'} - \gamma_\alpha{}^\dagger{}_{+\nu'} \gamma_{\alpha+\nu})\, d\alpha \quad . \quad . \quad . \quad (1)$$

It must not be thought that (1) is zero just because it can be split up into two integrals and the second integral can be transformed to the first by changing α to $\alpha + \nu'$ in it. The splitting of the integral appears to be not justified; when $\nu + \nu'$ is zero, each of the split integrals is divergent, for each of them represents the number of particles both in the positive states and the negative states. This is in fact the argument which implies $\infty - \infty$.

A careful application of the convergence criteria regarding the finiteness of the number of particles in the positive states and the number of holes in the negative states, presented in a report by Prof. Max Born and myself[2], will lead to the result that (1) has the value ν if b_ν and $b_{\nu'}$ are conjugate, and has the value zero if it is otherwise. Jordan[3] has also deduced this result by writing the photon operator in a form that does not involve negative indices.

Breeding Tests and Variations

IN NATURE of January 30, p. 197, Prof. T. F. Dreyer draws certain sweeping conclusions as to genetics and its limitations, from an experiment in which he produced visible abnormality and constitutional defect in 11 locusts by means of environmental treatment during development. He did not breed even an $F1$ generation.

Prof. Dreyer naïvely remarks that the abnormalities "remind one strongly of similarly localized (and similarly produced ?) abnormalities in *Drosophila*, and we may legitimately assume the abnormality will be hereditary".

Such a statement, in the present state of biology, can only rest on unfamiliarity with the facts. For it is a commonplace of genetics that only breeding tests can distinguish between hereditary and non-hereditary variation; and numerous workers, notably Goldschmidt, have directed attention to the frequent phenomenon of the complete identity of visible effect, in *Drosophila* and other organisms, of mutations due to genetic change and modifications due to environmental change and not inherited.

Prof. Dreyer's conclusions are thus founded on an elementary but basic methodological error.

Activity of Corticosteron in the Glucose Test in Rats

EIGHT days after extirpation of both adrenals, adult rats die in about 5 hours if fed with 2·5 gm. glucose (5 c.c. of 50 per cent solution)[1]. This test can be used to titrate adrenal cortical hormone both quickly and accurately.

By this method, the great activity of corticosteron, the active crystalline fraction of cortical extracts, can be clearly shown[2]. If 0·2 mgm. or more of corticosteron be injected subcutaneously one hour before the glucose is given, the adrenalectomized rats remain alive. With doses of 0·1–0·15 mgm., about 50 per cent of the rats lived, and with 0·05 mgm. or less all the rats died in 3–6 hours (with severe diarrhœa, as in the case of the uninjected rats). The active dose of corticosteron in this test is 0·2 mgm. (per rat of 150 gm.).

Scientific Worthies and Events commemorated on Postage Stamps

SOME time ago[1], reference was made in these pages to the fact that Ecuador had celebrated the centenary of Darwin's visit on September 16, 1835, by a special issue of postage stamps. These are not the first stamps of scientific interest. In 1923 France issued stamps bearing the head of Louis Pasteur, in 1927 Berthollet and later Pilâtre de Rozier. Louis Blériot and his pioneer flight across the Channel were commemorated in 1934. A recent issue also shows Pasteur at work.

Other countries, too, have issued stamps commemorative of scientific events or famous men of science. In Germany, last year, there appeared stamps showing portraits of Otto Von Guericke, Daimler and Benz; Italy has Volta, and a stamp which shows a portrait of Galvani, commemorating the Radio-Biology Congress in 1934; the United States a stamp issued in 1929 showing Edison's electric lamp. Special stamps were issued in Germany for the mails carried on the Graf Zeppelin's flight to Spain-Brazil-America in 1930, and again in 1936 on the flight to North America.

Mendeléeff appears on a stamp of the U.S.S.R., which also celebrated the bicentenary of the Academy of Sciences by a special issue in 1925. Hungary has two stamps for the tercentenary of the University of Sciences, whilst Yugoslavia remembers Nikola Tesla. So recently as last December, a set of Austrian stamps was issued showing six inventors—Weisbach, Schrauben, Von Ghega, Werndl, Lieben and Kaplan.

Points from Foregoing Letters

By expressing the age of the universe as derived from cosmological theories (2×10^9 years) in units provided by the atomic constants (e^2/mc^3), Prof. P. A. M. Dirac obtains a number comparable with the ratio of the electric to the gravitational force between the electron and the proton (10^{39}). He suggests that this ratio, and also that between the mass of the universe and the mass of the proton (10^{78}) are functions of the age of the universe. This leads him to the supposition that the amount of matter in the universe is constantly increasing while the gravitational 'constant' decreases. He introduces a new time variable ($\tau = \log t$) similar to Milne's distinction between 'dynamic' time as measured by pendulums, etc., and 'kinematic' time measured by radioactive and atomic phenomena.

A method is described by J. H. E. Griffiths and Dr. Leo Szilard for observing the capture radiation emitted by slow neutron absorbers. Using the capture radiation of cadmium as an indicator of the neutron intensity, the absorbing cross-section for slow neutrons is determined for a number of elements. The effect on the Geiger counter of the capture radiation from the eleven strongest slow neutron absorbers is observed. Though the atomic weight of these elements varies from 35 to 200, the effect per captured neutron is about the same for all of them. The number of quanta emitted per captured neutron is estimated for cadmium.

From the number and absorption coefficient of the 'resonance' neutrons and of the electrons which they liberate in a silver detector, C. Y. Chao and C. Y. Fu have estimated at 80–800 volts the average spacing between adjacent resonant levels effective for neutron capture.

A spontaneous increase in the resistance of supraconducting tin and tantalum, followed by a slower decrease, has been observed by Dr. F. B. Silsbee, R. B. Scott and Dr. F. G. Brickwedde, when the current is relatively high (about 2 amperes in a tin wire, diameter 0·0222 cm.).

By measuring the value of the persistent current in a single crystal of tin, by means of a supraconducting galvanometer, Prof. E. F. Burton and K. C. Mann show that the magnetic field necessary to initiate the restoration of resistance when the field is transverse is 0·58 of the value for longitudinal fields.

Commenting on the uncertainty concerning the affinities of the Sterckfontein ape, Dr. R. Broom mentions that the contact of the occipital fragment has now been found. The restored brain appears to be fairly comparable in size with that of the chimpanzee, but the teeth "resemble those of man".

A. Bentsáth, St. Rusznyák and Prof. A. Szent-Györgyi report that hesperidin and also the mother liquor of 'citrin' show properties which have been ascribed to vitamin P; quercitin, though nearly related in constitution to hesperidin, has no vitamin P activity. (The absence of vitamin P does not in itself affect the animals, but modifies the pathological condition produced by the lack of vitamin C.)

G. I. Crawford records the presence of *Eucrangonyx gracilis* S. I. Smith from the Lea Bridge Works of the Metropolitan Water Board. This amphipod has been previously found only in Canada and the United States.

The reasons why certain types of cross-cousin marriage are favoured and other types are not allowed in Assam is ascribed by Prof. J. K. Bose to economic factors arising during the intermingling of patrilineal and matrilineal clans.

L. Harang explains the regular annual variation of the critical frequencies of the E-layer and the inverse annual variation of the F_2-layer as due to different absorption of the solar radiation producing ionization in the layer. In the F_2-layer the ionizing agency is only slightly absorbed when passing through the layer; a variation of pressure will therefore strongly influence the production of ions. In the E-layer the ionizing rays are completely absorbed and the maximum electron production is fixed by the limited spectral energy and is independent of pressure variations.

Assuming that a connexion exists between the bivalent ions of the rare earths and the radio-photofluorescence bands, Prof. K. Przibram has tested calcium sulphate containing 10^{-3} thulium after exposure to radium rays with ultra-violet light, and has obtained actually a brilliant red fluorescence at low temperatures.

A criticism of the excessive attention paid to the stratigraphical side in the teaching of geology, at the expense of the chemical, physical and engineering aspects, a knowledge of which would be valuable in building and road research, is made by Dr. B. H. Knight.

The behaviour of serum of a number of cancer patients has been compared by Dr. R. Brdička with the behaviour of 'normal' serum, in its effect upon the current-voltage curve of a dropping mercury cathode, after suitable treatment devised to bring about the 'protein effect'.

Research Items

Buddhism in China

A CLUE to the essential quality, often miscalled materialism, in Chinese culture is afforded in a lecture by Prof. Hu Shih, of Peiping, on "Chinese Culture before and after Indianization", which was delivered on September 11, 1936, at the Harvard Tercentenary Conference on Arts and Sciences (*Science and Culture*, Calcutta, 2, 6). As was then pointed out, the Indianization of China affords material for the study of cultural borrowing on a grand scale such as is without comparable parallel anywhere, except perhaps in the Christianization of Europe. The contrasting elements in the culture of China and India stressed by Prof. Hu Shih were the factual outlook of early Chinese religion, a religion of a hard-working and plain-thinking people, and the imaginative and speculative elements in Buddhism, in which Chinese thought, as it became more sophisticated, found a much-needed and long-sought outlet. The rapid spread of Buddhism in the Yangtze valley suggests, it was maintained, that Buddhism had made considerable advances among the people at large, and especially the lowly, long before it was adopted officially in A.D. 68; while the readiness and completeness with which it was assimilated is shown by the fact that the great persecutions of Buddhism, of which the first took place in A.D. 446 and the last in A.D. 955, were none of them of lasting effect. At the same time, in adopting Buddhist concepts of divinity, the Chinese mentality did not fail to mould them to its own categories and needs. The god Avolokita, for example, changed his sex and became the goddess of mercy, while Maitreya becomes the familiar figure of a jovial monk. Nevertheless, the spread of Buddhism in China is not the least remarkable event in the history of that religion, for, as Prof. Hu Shih pointed out, there was an essential opposition in the two modes of thought, as is shown, for example, in the institution of monasticism, which made such great inroads on the population and wealth of China, though entirely opposed to Chinese economic ideas, while asceticism and disregard of family ties contradicted the whole of China's conception of the family and the obligations of, and to, posterity.

Dominance of Genes in Man

IN a paper on the problem of dominance in man (*J. Genetics*, 33, No. 3), Dr. S. G. Levit has made a careful study of a number of pathological genes in man, and concludes that a large majority are 'conditionally dominant', showing weak penetrance and hence frequently skipping a generation. Thirty-eight genes are classed in this category against 14 recessives and 3 indeterminates. It is recognized that some of the recessives, such as epilepsy and schizophrenia, are not always expressed even in the homozygous condition. The 'indeterminates' are sex-linked genes, which are limited to the male sex so that it is impossible to distinguish them as dominant or recessive. Hæmophilia and night-blindness, usually classed as male sex-linked, are placed here, while colour-blindness, another sex-linked condition, is regarded as intermediate, since female heterozygotes have recently been shown to exhibit a partial expression of the condition. It is pointed out that genes which are conditionally dominant in the heterozygote tend to express themselves at a late age, while genes which are recessive (in the homozygote) tend to appear earlier. The evolution of dominance is discussed, and it is concluded that, as natural selection has played a decreasing role in civilized man, the mutant genes of more recent origin have retained some of their original dominance while the less numerous recessive genes are older in origin. This encounters the difficulty that many genes may be expected to have occurred repeatedly at different periods.

Yolk of the Egg of Salmon

THE egg of the salmon, *Salmo salar*, contains a large quantity of yolk, and F. R. Hayes and D. M. Ross (*Proc. Roy. Soc.*, B, Dec. 1936) have studied the manner in which this is utilized during development. During this process fat is used up (burnt) and stored in the embryo, and the total of these two amounts is defined as the fat absorbed by the embryo from the yolk. The rate at which these processes take place is estimated by taking samples of a hundred eggs at a time at various intervals from a few hours after fertilization until the absorption of the yolk sac, and the results are given in graphical form. These curves are compared with the well-known curves for the chick, and when the necessary corrections for the difference in time are made, the resulting curves show considerable similarity. Thus it appears probable that the sequence of energy sources, that is, carbohydrate-protein-fat, is the same in these two widely differing forms.

Metopa Grœnlandica in a Lamellibranch

K. STEPHENSEN and G. Thorson describe an interesting case of commensalism (*Meddelelser om Grønland*, 118. No. 4. 1936). *Metopa grœnlandica* has been recorded from inside ascidians both in north and west Greenland and in the Mount Desert region, Maine, U.S.A., whilst other species of the genus were found in *Actiloba* and in association with the medusoid *Phialidium* from Millport, Scotland; but apparently this is the first time it has been seen in a bivalve (*Pandora glacialis*). This bivalve is a high arctic circumpolar species, the southern limits of which are east Canada and the Murman coast, but it does not occur in west Greenland and Iceland. Its mantle lobes are united almost entirely, and are only free at the anterior end to allow the foot to pass out. Thus the habitat must be a natural one for the *Metopa*, although peculiar and with little available space as the shell has one valve quite flat and the other only slightly convex. The *Metopa* adheres to the gills of the mollusc by sticking its antennæ between the lamellæ, or it lies free, back downwards, head pointing towards the caudal end of the host. Quite young specimens of the amphipods and also adults were found, which probably indicates that breeding takes place within the mantle cavity of the shell. Out of twenty-three *Pandora*, eight contained *Metopa*.

Effects of Cyclone on Coral Reef

In the Reports of the Great Barrier Reef Committee, vol. IV, Part II, 1936, Mr. F. W. Moorhouse records the effects of a cyclone in 1934 on Low Isles, North Queensland. This was the island on which the Great Barrier Reef Expedition had its headquarters in 1928–29. At that time, the island and reef were surveyed in great detail and Mr. Moorhouse, who was himself a member of the expedition, has been able to give valuable information on the destructive effects of the cyclone and the changes that it wrought in the formation of the reef. The effects of lowering of the waters of the moats on the perforate coral *Porites* are dealt with in some detail. The polyps of the newly exposed zones of the coral appear to become stimulated and an increase in lime deposition follows. This deposition takes the form of sharp pointed spines. As a result of the constant expansion and retraction of the polyps over these spines, the tissue becomes penetrated and the spines are exposed to the exterior. The bared spines become settling points for filamentous algæ. As the algal growth increases, sediment is held by it, which can no longer be removed by the polyps. As a result they become smothered. The whole process takes several months.

Cytology of *Agave*

The century plants of the genus *Agave* include *A. sisalana* and various other species native to Mexico and Central America but now widely grown in the eastern tropics as a source of fibre. In connexion with breeding experiments at the Amani Agricultural Research Station in Tanganyika, Mr. L. R. Doughty has examined the chromosomes of various species (*J. Gen.*, 33, No. 3). He finds that *A. amaniensis*, a new species of unknown origin found growing in the plantations, is diploid, having $2n=60$ chromosomes, 10 long and 50 short. In addition to two other diploid species, *A. cantala* is found to be triploid, *A. Zapupe* tetraploid, *A. fourcroydes* and *A. sisalana* approximately pentaploid ($2n = c.\ 140$). That these species are autopolyploids is shown by the behaviour of the chromosomes, which frequently form trivalents, quadrivalents and pentavalents in meiosis. The species are of limited natural distribution and nearly related. Breeding experiments indicate that they are heterozygous. The diploid species will cross with one another and with polyploid species. The diploid species fail to set fruits at Amani, and even with artificial pollination the setting of seed is low. *A. sisalana* becomes partially fertile under certain conditions which appear to be connected with the formation of the abscission layer at the base of the ovary.

Phytopathology in India

A section of "Biochemical and Allied Research in India, 1935" (pp. 100–112) summarizes the investigations into Indian plant diseases during 1935 and previous years. A reprint of the section has been received from the author, Dr. B. B. Mundkur, and shows a gratifying amount of research work in progress. Cereal diseases are mainly represented by the smuts and *Helminthosporium* troubles. A new disease of gram (*Cicer arietinum*), caused by a species of *Mystosporium*, was reported by Mitra during the year, and a new virus disease of til (*Sesamum indicum*) made its appearance (Pal and Nath). The immunity of Indo-American strains of cotton to the Indian strain of the fungus *Fusarium vasinfectum* has been compared with the susceptibility of Indian cottons. Diseases of the sugar-cane, of fruit trees, and other crops, are further considered. Dr. Mundkur has also two recent articles in the *Indian Journal of Science*, on the "Systematic Position of the Smut causing Malformation of *Vitis quadrangularis*" (6, Pt. 3; June 1936) and "A Rhizoctonia on Sweet Potatoes in Bombay" (6, Pt. 4; Aug. 1936).

The Geological Time Scale

Following up his important work on the determination of the age of the Keweenawan basalts (510–560 million years) by the helium method, W. D. Urry has now applied the latter to small groups of basic igneous rocks representative of many of the geological horizons above the Keweenawan (*Bull. Geol. Soc Amer.*, 47, 1217). The results include the following:

		Millions of years
Pliocene	Basalt, Steens Mt., Oregon	13 ± 1
Miocene	Basalt, Douglas Creek, Washington	17 ± 1·5
Oligocene	Basalt, Lower Silesia, Germany	36 ± 2
Early Cretaceous	Little Hatchet Mts., N. Mexico	85 ± 3
	Dykes cutting the Nevadan Granodiorite	90 ± 4 110 ± 7
Late Jurassic	Nevadan Granodiorite	110 ± 5
Triassic	Palisade Sill, New Jersey	165 ± 8
	West Rock Sill, New Haven, Conn	170 ± 12
	First Flow, Watchung Mt., N Jersey	180 ± 11
Permian	Basalt, Brighton, Mass	230 ± 15
Devonian	Newbury volcanic rock, Mass.	300 ± 10
Ordovician	Diabase in Martinsburg Shales, Pa.	355 ± 15 375 ± 15
Cambrian	Basalt, Unicoi formation, Tenn.	440 ± 30 465 ± 30

Brief descriptions are given of the analysed specimens, and it is shown that the ages found are consistent with those obtained from strongly radioactive minerals by the lead method.

Nature of Atmospherics

E. V. Appleton and F. W. Chapman (*Proc. Roy. Soc.*, A, 158, 1) have published the latest stage of their investigation of atmospherics, which appears to mark a distinct advance in the study of atmospherics and of thunderstorms. An aperiodic elevated aerial was used as in the classical experiments of C. T. R. Wilson, but the potential changes were recorded by a cathode ray tube with a screen which gave a persistent image. This was photographed automatically, the camera shutter being itself tripped by the transient discharge. As is to be expected, the field change produced by a lightning flash nearby is mainly due to the electrostatic effect of the change in charge distribution, while the field at a great distance is that due to electromagnetic radiation. This results in a progressive change in the wave form of the atmospheric at increasing distance from the source. The picture obtained from a near discharge shows a change of field taking place usually in a series of steps, as may be expected from moving-plate photographs of lightning flashes. The first part of the discharge is often comparatively slow, corresponding to the 'leader stroke' of the flash photographs. During the period of maximum current, there are often superposed pulsations with quasi-periods down to 10 micro-seconds. The atmospherics observed at great distances commonly show several quasi-periodic half-cycles, and sometimes a tail with much slower cycles. These changes in shape as the disturbance is propagated are possibly caused by dispersion in the ionosphere.

Automatic Regulation of the Temperature of a Room

PERHAPS the most difficult problem in connexion with the automatic control of the temperature of a room is to find the most suitable spot at which to fix the thermostat. In an article in the *Electrical Contractor and Retailer* of January, it is stated that the British Thermostat Co., Ltd., has been able to show that for the vertical walls of the room there is a cushion of air extending about 1¼ in. from the wall surface in which, owing to the existence of convection currents and other causes, the temperature varies considerably. Further, owing to heat exchange between the outside and inside of a wall, its temperature is continually changing. To avoid these sources of error, the British Thermostat Co. has recently introduced a new design of room thermostat. The main features of the design are, first, that the sensitive element is spaced sufficiently far from the wall to avoid the abnormally heated air cushion; and secondly that the contact area between the back-plate and the wall is small and the conductive heat path between the back-plate and the main body of the instrument 'housing' is at the top of the instrument, so that conducted heat, already reduced to a minimum, has little effect on the sensitive element. The thermostat is contained in a vertical bakelite tube open at the top and bottom to permit free circulation of air, and thus assists rapid operation. The instrument has an adjustable setting scale, the standard range being from 45° to 75° F., and operates on a differential of 3° F. If required, a locking device can be fitted to the setting scale so as to prevent unauthorized interference.

Iron-Nickel Alloys of High Permeability

IN a paper read by W. F. Randall before the Institution of Electrical Engineers on January 8, a most interesting summary is given of the metallurgy and magnetic properties of the remarkable group of iron-nickel alloys of high permeability. Difficulties experienced with the first 'permalloy' containing 78·5 per cent of nickel have led to its substitution by iron-nickel alloys containing other metals, and in this paper the copper alloy known as 'Mumetal' is specifically considered. Details of the manufacture of the strip and of its practical heat treatment are given, together with a fairly detailed treatment of the factors which determine its magnetic characteristics. The paper ends with a short account of the testing methods employed and of the practical applications of this material for loading cables, for the cores of instrument transformers, transformers and chokes for radio apparatus, magnetic screening, magnetic relays and the armatures for moving-iron instruments.

Solubilities in Deuterium Water

PUBLISHED measurements of solubilities of salts in deuterium water have been limited to a few determinations near room temperature. R. W. Shearman and A. W. C. Menzies (*J. Amer. Chem. Soc.*, 59, 185; 1937) have now measured the solubility of potassium chloride in 98·2 per cent deuterium water from 0° to 180°, the total weight of deuterium water used being 1·39 gm. By comparing the solubilities with those in ordinary water, a short linear extrapolation gave the solubility in pure deuterium water. The solubility was lower than in ordinary water, but increased faster with temperature. From about 60° to 180° the solubility difference is approximately a linear function of temperature; the more rapid increase with temperature below 60° may be connected with changes of the average configurations in liquid water. The authors emphasize that, contrary to a prevalent belief, deuterium water is not always a poorer solvent for salts than ordinary water (cf. NATURE, 138, 121; 1936).

Inorganic Chromatographic Analysis

THE adsorption method of analysis known as chromatography, which has been used with such marked success in the investigation of the carotenoid field of organic chemistry, and in the examination of many other complicated organic molecules, has now been applied by Schwab and Jockers (*Naturwiss.*, 25, 44; 1937) to the problem of the separation of inorganic cations. The method depends upon the fact that the different cations are adsorbed to different extents by aluminium oxide. The solution containing the cations to be separated is poured over a column of alumina. As it runs through, the cations are adsorbed at different positions in the column. The column is then washed and 'developed' by passing through it a reagent, usually ammonium sulphide, which forms coloured compounds with the adsorbed cations. Coloured rings are thus produced in different parts of the column, by means of which the different cations present in the mixture can be detected. From neutral aqueous solutions of nitrates of the metals the cations are adsorbed by alumina in the following series: antimony, bismuth, chromium, ferric, uranyl, lead, mercuric, cupric, silver, zinc, cobalt, cadmium, nickel and manganese. In some parts of the series, however, the adsorption rings are very close, and separation is difficult. Hydrogen ions are themselves adsorbed rather more strongly than most cations. The adsorption series is different when solutions of the cations in ammonia or alkaline tartrate solutions are used. A practical use of the method lies in the detection of traces of elements lying high up in the adsorption series in those adsorbed further down. Thus, a trace of iron in copper or cobalt solutions, or a trace of copper in cadmium or cobalt solutions, is readily detected.

The Stellar Problem of Three Bodies

PROF. E. W. BROWN has recently published two papers on this subject (*Mon. Not. Roy. Astro. Soc.*, 97, 1; November 1936). He limits the solution to those terms which may be capable of being detected by observation at present and in the immediate future. In the first paper, "Application of Satellite Theory", where he shows how a literal satellite theory could be adapted to the stellar problem, the results are useful only when the eccentricities and inclinations are small. This restriction is removed in the second paper, "The Equations of Motion With a Simplified Solution", where nearly all eccentricities and inclinations can be included. In both cases, however, there is one important limitation; no periodic term which has the square or products of the ratio of the periods and that of the mean distances as a factor of its coefficient can be detected by observation. After dealing with the satellite problem a simple rule for deducing the stellar problem is given, and it is shown that this rule holds good for the second, and hence for all higher approximations.

Optical Lenses moulded from Plastic Material

An interesting exhibition of optical lenses moulded from plastic materials was held on February 9 at the Waldorf Hotel, London, under the auspices of the Combined Optical Industries, Ltd. Those responsible for the production of the material and for the process of moulding it are Mr. A. Kingston, the inventor, and Mr. Peter Koch de Gooreynd, chairman of the company, who has been associated with the development of the process.

It is claimed that this invention, which is British in origin and development, offers an opportunity for the increase of an industry in which Great Britain has hitherto taken a comparatively small share. The optical medium is produced from various plastic and transparent materials of a resinous character. It is originally prepared in sheets, which are guillotined into strips and then into small squares. These are subjected to a special treatment in which compression and the maintenance of temperatures of varying degrees play an essential part. The refracting surfaces are produced by moulding, and lenses polished and ready for mounting are delivered from specially designed machines. The long and difficult process of grinding at present necessary in the manufacture of optical systems is thus avoided, and it is evident that the cost of the production of the essential parts of optical instruments can be very greatly reduced.

The lenses shown at the exhibition were made of a particular form of the plastic material known by the trade name of 'Perspex'. It is a substance of high transparency, very light, being about half the density of glass, and practically unbreakable. It is possible to throw one of the lenses with great force on to a marble table without damaging the surfaces so far as can be seen by eye. It appears that the material can recover from a considerable degree of strain without apparent permanent set.

The refractive index of the material has been determined by the method of apparent depth and was found to be approximately the same as that of crown glass. It is extremely transparent in the ultra-violet region extending to 2700 A. but is more absorbent in the infra-red.

These properties of the material suffice to show that it has the right to be regarded as a valuable optical medium, which may well exercise a revolutionary influence in the optical industry. Cameras, spectacles, range-finders and similar apparatus can be produced more quickly and cheaply and in a more robust form in this material than in glass. A striking exhibit was a photograph enlarged about twenty times showing excellent detail. Small opera glasses exhibited very little colour effect, although it is true that the magnification was not more than three diameters.

Certain questions naturally arise as to the possibility of the development for the manufacture of accurate scientific apparatus, where it is essential to eliminate the effects of aberrations. It appears that a number of different kinds of plastic materials is available, and, if they can be produced with the right dispersive powers and refractive indices, there is obviously a great future for the material in the field of research.

It appears that surfaces can be silvered. Can they be produced optically flat, and is the medium so optically perfect that it can form a Lummer plate ? We do not know if information on such points is available yet, but enough was shown at the exhibition to supply convincing proof that, in the wide and extending field where optical instruments come into contact with modern life, this medium will play an important role.

The British Electrical and Allied Industries Research Association

The sixteenth annual report, covering the period from October 1935 to September 1936, of the British Electrical and Allied Industries Research Association, now usually called E.R.A., has been published. It shows that its research work is rapidly increasing in magnitude and importance. When the formation of research associations in Great Britain was first considered some twenty years ago, their value to industry was considered highly problematical by many. This distrust is now completely dispelled. It can be proved that their work has resulted in the saving of millions of pounds every year to the consumers. In the electrical industry alone it has resulted in a great increase in the continuity of the supply and the length of life of the cables and the efficiency of the lamps.

Knowledge cannot be gained without expense. The funds contributed by the manufacturers and the equal contributions from the Government are converted into 'knowledge stock' which the chairman of the council of E.R.A. calls a priceless national asset which repays the investor by ever increasing dividends of prosperity and progress. There are 450 voluntary workers, some of them well-known experts, serving on the various committees of E.R.A. The electrical industry is one of the best organized in the country and now fully recognizes the commercial value of research. Within its present field there are many problems still to be solved by E.R.A. When solutions are obtained, some of them will doubtless lead to the active development of profitable branches of the industry.

A very happy state of affairs is disclosed in the report by the way this Association co-operates with the leading engineering institutions, with numerous international committees, with the Electricity Commission, with the G.P.O., the B.B.C. and the Radio Manufacturers' Association. Its financial position is very sound. It has built up its laboratory at a cost of £26,000 out of its own reserve fund. Out of a total income of £68,000 last year, the Department of Scientific and Industrial Research contributed £19,000.

Of individual researches, we may mention the research on the electric strength of thin dielectrics and varnish films. The electric strength of mica has been found to be constant up to 300° C. This value agrees with certain calculations based on recent theories. The oscillographic studies of the current and voltages which occur during a breakdown have led to valuable practical results. A research is proceeding on the deleterious effects of ionization products and coronæ (brush discharges). Two papers were presented on behalf of E.R.A. to the British Association, by Dr. S. Whitehead and Prof. W. M. Thornton respectively. The latter is also revising the tables for spark-gap calibration.

Important tests were carried out with the co-operation of the Central Electricity Board, on the Portsmouth–Reading line, on the interference produced by high harmonics in neighbouring circuits, and a report will also be issued. A number of reports on interference were presented to the Commission Mixte Internationale, and some of the conclusions put forward were incorporated in the final recommendations. The issue of a report by the Institution of Electrical Engineers on electrical interference with broadcasting brought the large-scale co-operative researches co-ordinated by E.R.A. to a close. They have been superseded by a series of investigations which aim at (1) obtaining accurate data and limits for standard specifications and (2) compiling reports upon specific matters of interest to manufacturers of electrical plant. In railway engineering research, it has been found that cadmium–copper wire shows considerably less wear than pure copper as a trolley wire material; the small quantity of cadmium present only reduces the conductivity of the wire by a small amount. Its freedom from stretching makes this alloy of copper very suitable for use as a trolley wire.

The report is published by E.R.A., 15 Savoy Street, W.C.2.

International Fisheries Research[*]

THE twenty-ninth reunion of the Conseil Permanent International pour l'Exploration de la Mer was held in Copenhagen in May 1936 under the presidency of Mr. Henry B. Maurice. The present position being unchanged, all the States now participating will continue for another five years as from July 22 of last year. Latvia is now desirous of becoming a full member.

Among the many subjects involved was the position of the various countries as regards size limits and mesh regulations (Point 7 of the agenda), the president having circulated a memorandum previously prepared by himself summarizing, so far as was possible, the present position with regard to mesh regulations and size limits.

Three special scientific meetings were held during the Council meeting of 1936, the first to discuss the physiological problems of interest to the marine biologist in his studies of the most important species of fish, the second to compare stocks of fish in the several areas in respect of age composition, the third on the measurement of submarine light and its relationship to biological phenomena. The programmes and reports of the different area committees are included in Part 1 of the *Rapports et Procès-verbaux*.

Part 2 includes the Administration Report, which was passed without amendment. A large part of this has to do with the herring. A special meeting of herring experts was held at Lowestoft on October 16–17, 1935. Besides the report with recommendations, there are papers on the herring from the Skagerak, Kattegat and Baltic, Fladen Ground, Western European waters, the Southern Bight, the southern part of the Transition Area, Faroes, Iceland and Greenland, and from Scotland, also others on race questions, populations and larvæ. M. le Gall's paper on the present state of knowledge concerning the origin and distribution of herring populations in western European waters was specially discussed.

The following recommendations were made. Any group of herring spawning in a given area at a given season from year to year should be defined as the natural 'Biological Group', and morphological characters should be used as a practical aid in the identification of these biological groups outside the area and season of spawning. Work on biological groups and other local and seasonal population should be continued. Vertebral counts of selected material should be continued, additional characters such as the number of keel scales being also studied when necessary. A co-operative study should be undertaken on the practicability of utilizing a count of separate portions of the vertebral series in such a way as to draw distinctions between morphologically distinguishable groups with a minimum of labour and material. Spawning times should be defined by stating the actual month, and in the northern area group, characters of the autumn and spring spawning populations on the north-west coast of Iceland should be investigated and compared. All countries working in one way or another in the waters of the Faroes, Iceland and Greenland should arrange for material of herring to be collected for age determinations and distribution of larval stages; fishing experiments should be carried out in the open sea between Norway, Faroe Isles and eastern Iceland to collect material in order to get information as to the exchange of population between different parts of this region; and the collecting work concerning age composition, population-characters, exact determination of maturity and distribution of larvæ should be carried out in all important areas systematically and continuously for a period of years. Samples of spawning herring from the Viking Bank should be collected and investigated as opportunity occurs; samples from western Greenland and from Labrador should be collected with the view of comparing the population characters, age composition, spawning time and growth. It is of importance for the international work that contact be maintained with the herring investigations in Russian northern waters by the U.S.S.R. Further, it was recommended that in the North Sea and Channel Area the following problems be investigated: the three subgroups of 'autumn' spawning herring of the North Sea, the degree of mixing, if any, in the winter spawning herrings of the southern North Sea and Straits of Dover, the herring of the Smalls, the mixing on the Fladen Grounds and the herring population in general in the Irish Sea; that further investigations be carried out in the Skagerak, Kattegat and Baltic as regards the 'autumn' spawning population of the Kattegat, co-operation being necessary between Denmark and Sweden, and that population investigations be carried out on the eastern coast of the Baltic, on a co-operative basis between the countries concerned.

[*] Conseil Permanent International pour l'Exploration de la Mer. Rapports et Procès-verbaux des Réunions. Vol. C. 1$^{\text{ère}}$ partie: Procès-verbaux (Mai 1936). Pp. 62. 3.00 kr. 2$^{\text{ème}}$ partie: Rapport administratif (1935–36). 3$^{\text{ème}}$ partie: Appendices. Pp 111+25. 4.00 kr. (Copenhague: Andr. Fred. Høst et fils.)

A second special meeting of experts from the Baltic countries met at Copenhagen on December 4-5, 1935, to examine more closely the question of further measures to protect the stocks of fishes in the Baltic. The meeting dealt mainly with the flounder and salmon, and recommended further protective measures.

The third part of the Report (Appendices) contains several papers, including one by F. S. Russell on "The Importance of Certain Plankton Animals as Indicators of Water Movements in the Western End of the English Channel" and "Handliste zur Sicherung der Bestimmung nordischen Plankton" by H. H. Gran, E. Hentschel and F. S. Russell. The latter paper is an attempt to list the more important plankton organisms, both micro- and macro-plankton, plant and animal, in order that it may be seen at a glance which to record in any preliminary plankton investigations. Only those species which can be identified easily are included, and if two or more important species of a genus are easily confused the genus only is given.

The Natural History of Barra, Outer Hebrides*

EDINBURGH has been enterprising and has adopted the island of Barra in the Outer Hebrides as a centre of its natural history activities. The Biological Society of its University produced eight zoologists, seven botanists and four geographers and geologists who invaded the island, camping there for the first fortnight of July.

The island is a useful size for this purpose, about 8½ miles long by 5½ miles broad. This gives only about twenty-five square miles of land, as it has a much indented coast, with many sandy bays between rocky headlands. Its central parts are about 700 ft. high with hills to the south of 1,260 ft. and 1,092 ft. The geology was already known, the surface being peat moor with rocky knolls and ridges of gneiss with intervening boggy hollows. The character of the coastal scenery is said to suggest recent subsidence, some of the inlets appearing to have been originally freshwater lochs. Heavy south-west winds dominate one side, carrying the shell-sand over the peaty soil and producing excellent grazing grounds (machair). Once completely afforested, there are now only three patches of woodland. Lastly, there are nine freshwater lochs, these containing about 0·2 per cent calcium, 0·02 per cent chlorine and pH 5·6–7·4.

Clearly, in this diversified island of Barra there was plenty of room for the botanists. To commence with, one party had to collect and determine all the species of plants dwelling there, while another set to work to see how far the vegetation had been segregated into communities. Coastal areas, moorland, loch, woodland and cultivation were recognized, and lists are given of the higher plants found in each; these are obviously incomplete, being collected in a restricted season, but serve to indicate the associations. The layman would remark that this section consists largely of Latin names, whereas the botanist would see a necessary start. The lochs are particularly interesting, one set with a rich lacustrine and a poor marshland flora and a second set with opposite characters—it is not clear how far these are due to topographical conditions. Of the lower plants there is a particularly rich moss and liverwort flora, 85 and 21 species respectively. To these must be added 27 species of pteridophytes, 42 fungi and 30 lichens—while evidently one botanist was interested in marine algæ, of which 78 species were named, here an evident correlation with the relatively warm, oceanic waters.

Inasmuch as the fauna is a consequent of the flora, it cannot be collected in any completeness without a knowledge of the latter—and in any event there are many forms which are seasonal. All we can say is that an excellent start has been made on the land fauna. At this stage it is a mere list of the species, for as the authors say, "it would be premature to discuss the animal ecology". The lists vary in value; thus Waterston's section on land and freshwater Mollusca records 51 species in Barra as compared to 64 species known from the whole Outer Hebrides and contains excellent notes on their distribution. There is an element of completeness here, as indeed there is in respect to the whole freshwater fauna. In contrast, the insect fauna probably does not record a third of Barra's species—and lists of the marine fauna are obviously out of place and of little value.

Now is there to be a sequel of a further expedition by the Edinburgh Biological Society to Barra? The preliminary work has been done and upon this the plan for a serious attack on the ecology can be based. The island must be so mapped as to show the distribution of the plant communities and the proportions of the various species in these determined. Then the animals associated with each plant community must be collected and such species as are of general distribution or are chance visitors eliminated. This will entail a study of the physiological connexions of the animals with their environments and of their numbers of individuals. The island is small enough and its parts so clearly defined that valuable ecological results seem certain. Lists of the species of animals and plants in any locality cannot form a natural history; for this science is one of life, not of death. Edinburgh has a great University and it may perhaps be invited to bring its work to full fruition, even if it means student-expeditions at different seasons extending over several years.

Proc R. Phys Soc., Edin., **22**, 241-96 (1936).

East African Rift Valleys*

J. W. GREGORY'S classical work on the rift valley in Kenya focused attention on the rift valleys of Central Africa, and the historical retrospect given by Bailey Willis at the beginning of the recent Carnegie Institution volume on the subject provides a summary of the views of the pioneers, though there are some notable omissions both in this and in the bibliography.

The work consists of two principal parts: the first giving the 'general picture' with a hypothesis of rift valley formation, and the second detailed characters of the several areas, which include the coastal region of Tanganyika and the Tanganyika plateau, Lake Victoria and the central plateau, and also the rift valleys, Lake Albert with the Ruwenzori range at its southern end, Lake Tanganyika, the Rukwa trough, Lake Nyasa, the Ruaha trough, the classical rift valley (called Gregory Rift Valley throughout the work), and Lake Rudolf. A chapter on the volcanoes is given, and shorter chapters on earthquake conditions and on gravity tests. So little space is devoted to seismology that it might be wondered why this volume is one of the series in the studies of that science until it is realized that the work forms a very suggestive basis for a seismological study, and it is probable that the seismologist will be best qualified, when more data are available, to decide whether the general hypothesis will stand. It is likely that the physicist will object to some of the theories put forward, where conceptions such as anti-gravity or levity, downdraft and suction, are given the status of scientifically defined forces acting in the crust of the earth and capable of forming the structures under consideration.

A brief outline of the main thesis is here attempted. An area of uplift where the high plateaux of Central Africa are developed is situated over an asthenosphere consisting of "relatively incompetent but solid elastic rock". By gradual heating, probably by radioactive processes, this asthenosphere becomes a molten body, or asthenolith, which is covered by the competent shell about twenty-five miles (40 km.) thick. The melting of the magma causes an expansion in volume and hence a forcing up of the central area, while various forces at the margins, which are rather convincingly described, cause the edges to sink down. The author points out that the great plateaux "exhibit a tendency to a circular form" and shows (p. 72) that "this is strikingly the fact in the case of that plateau which is most completely surrounded by rift valleys of East Africa, the Tanganyika plateau and its northern extension beyond Lake Victoria".

We are to suppose that the large central plateau is the raised cover of the asthenolith of molten magma twenty-five miles below, and that the rift valleys and troughs, and the upraised masses of Ruwenzori and Elgon(?) are round the edges, and that any escapes of magma to give volcanic eruptions also lie round the margins. This roughly fits the facts, and it must be noted that the central cover is thick enough to have prevented any eruptive or intrusive activity since Karroo times.

The details of structures which form the second part of the volume constitute a mass of information very usefully assembled together. Bailey Willis is to be congratulated on having reached the top of the rim of the great Ngorongoro hollow and found that it is not a giant crater as stated by Jaeger. He warns the reader who visits Lake Tanganyika not to be disappointed, as he was, on first seeing that mighty trough which is almost filled with water (p. 185). There is very little evidence for a central core of greenstone to the Ruwenzori range, as postulated by the author, and the basic intrusive rocks known on the mountains are far older than the uplift of the mass. There is some confusion between Mgahinga, a volcano almost as large as Muhavura and Sabinyo, and Gihinga, a small cone to the north-east.

This important and stimulating work is beautifully printed, with few misprints, while the plates (many of which appear to be from infra-red photographs and most of which are by the author) much enhance the value of the volume. It will be read by all geographers and geologists, as well as by seismologists, who are interested in rift valleys in Central Africa, and will be referred to by those who are now working in, or studying, that most impressive part of the globe.

WILLIAM C. SIMMONS.

Breeze and Clinker Aggregates

THE Department of Scientific and Industrial Research has issued a revised edition of a bulletin published some years ago on "The Properties of Breeze and Clinker Aggregates and Methods of Testing their Soundness" (Building Research Bulletin No. 5. London: H.M. Stationery Office. 6*d*. net). Since the original publication, investigations carried out at the Building Research Station have established the cause of the occasional failures of these materials and have enabled tests to be devised which are suitable for application under ordinary working conditions.

'Clinker', or well-burnt furnace residue, and 'breeze' —the name applied to the smaller and less definite residues—usually contain a proportion of unburnt fuel, which has been proved to be the cause, when these materials are used as aggregates, of cracking which develops and becomes visible in the set concrete at various periods after pouring, by reason of the swelling movements which these unconsumed coals undergo in the mass. Certain types of coal are more likely to give trouble of this kind than others and, it is stated, the extent of the action can be predicted from the physical properties of the coal from which these aggregates were originally derived. For laboratory purposes, samples of coal are distinguished by their power of removing the colour from an aqueous solution of methylene blue and by their relative moisture absorption properties, and it is suggested that the presence in the aggregate of as little as 4 per cent of a coal of the most dangerous class may be sufficient to cause failure.

Investigations made on the setting and maturing movements in breeze and clinker concretes, and on the influence of sulphur and of water content, are described, while it is also explained why these aggregates may not be used in reinforced concrete construction owing to the rapid corrosion resulting from their permeability. Of the two tests recommended, the 'pat test' is said to be reliable in the majority of cases. A standard pat is made by mixing a sample of the material under test with fine white plaster of Paris, and a normal Portland cement; if in a period of 1–4 days this exhibits certain defined symptoms of movement, the material is to be judged unsound and must be rejected.

Fossil Algæ in Boghead Deposits

BOGHEAD coal is a comparatively rare and valuable material yielding gas and paraffin on distillation. It is characterized structurally by the presence of minute 'yellow bodies', the nature of which has been a subject of discussion. An algal nature was suggested for these in 1889 by Edgeworth David, but their peculiar properties in resisting decay and compression prevented any general acceptance of this view. Since that time, reports of C. E. Bertrand and Renault, Zalessky, and Thiessen have supported the algal view, and finally P. Bertrand in 1930 came to the conclusion that the *Pila* of C. E. Bertrand and Renault was *Botryococcus* and their *Reinschia* a member of the Volvocales.

The subject has now been placed on a much surer basis by a detailed study of living *Botryococcus Braunii* and material from the muds of glacial lakes and more recent peat deposits by Dr. K. B. Blackburn, and a re-examination of the 'yellow bodies' of boghead deposits by Dr. B. N. Temperley (*Trans. Roy. Soc. Edin.*, 58, 1935–36). Dr. Blackburn has followed the alga through its many variations in form; she shows that the inner membranes of the cells are cellulose, but external to this each cell has, towards the periphery of the colony, a cellulose and pectin cap, which contributes to the general mucilage surrounding the colony, whilst towards the centre of the colony, a thick fatty thimble forms around each cell, and these constitute the general matrix of the colony. The cuticular nature of these thimbles would explain their resistance to decay. The cells are rich in oil and also contain appreciable quantities of starch.

Dr. Temperley finds that the 'yellow bodies' described as *Pila* show extremely close agreement with *Botryococcus Braunii*, the various polymorphic forms of which are recognizable in the deposits. The form *Reinschia*, formerly ascribed to the Volvocales, differs from *Pila* in the hollow form of the colonies, but the details of structure correspond so closely with those of *Botryococcus* that Dr. Temperley concludes that "there is no doubt that the various forms of *Reinschia* and *Pila* are fossil colonies of the same type of alga".

Science News a Century Ago

Medicine in Chili

"THE science of medicine has hitherto made but small advances in Chili. . . . Twenty years ago medicine was practised by men of colour and the most ignorant quacks, the hospitals were entirely under the control of the monks, and the few well informed physicians, those, namely, who had received an European education found in Lima a more lucrative field for their exertions than was offered to them anywhere in Chili. This state of things, however, no longer obtains, for the number of physicians is now even greater than necessity requires, and there is a college at Santiago at which medicine is taught, although on a somewhat compendious plan. Still there is a scarcity of educated practitioners in the country, where the healing art is chiefly exercised by matrons and old Indian women. The country people are tolerably familiar with the virtues of the rather numerous indigenous plants, but to many of them properties are attributed which the individuals in question do not really possess, and many other remedies supposed to be of great efficacy are solely indebted for the estimation in which they are held to a credulous superstition. When any particular part of the body is the seat of disease, the remedy is sought for in the corresponding part of some animal, variously prepared; thus for ophthalmic disorders the carbonized eyes of birds of prey are administered, the claws of the condor are given for gouty pains of the hands, and the flesh of the smooth-skinned lizard for scurfy affections of the skin." (*London Medical and Physical Journal*, February 18, 1837.)

The Colony of Western Australia

AT a meeting of the Statistical Society held on February 20, 1837, Lord Glenelg, then Colonial Secretary under Lord Melbourne, communicated "A Report of the Committee of Correspondence of the Colony of Western Australia". Known first as Swan River Settlement, Western Australia was formed into a province in 1829, and the towns of Perth, Freemantle and Guildford were founded the same year. The development of the colony, however, had been slow. The report consisted of nine sections written by different individuals and dealt with agriculture, live stock, shipping, commerce, population, crime, religion and other matters. The total population of the Swan River Settlements west and east of the Darling Mountains was but 1,550. Sheep farming was the principal industry, there being in the York district east of the Darling Hills about 5,000 sheep in excellent condition. The original flocks were imported from "Van Diemen's Land". The animals were a large-framed and very coarse-wooled breed, but being crossed with Merino rams, the quality of the wool was constantly improving. The merino flock consisted of about 900 pure descendants of the choice Spanish flock presented in 1791 to George III by the King of Spain. This breed had much improved since imported into the colony. The amount of wool shipped for England and the Cape of Good Hope in 1836 was 12,500 lb.

The East India Company's S.S. *Berenice*

ACCORDING to *The Times*, on February 22, 1837, the East India directors gave a dinner at the West

India Dock Tavern, Blackwall, to Captain Grant and the officers of the S.S. *Berenice*, which was being prepared to leave for India. This vessel was the first steamship for the East India Company contracted for by the famous engineer and shipbuilder Robert Napier (1791–1876), and her success had much to do with Napier being entrusted with the contracts for the earliest ships of the Cunard Company. The *Berenice* was 170 ft. long by 28·8 ft. broad and of 646 tons with engines of 250 nominal horse power. She was a wooden paddle vessel; her boilers working at a very low pressure were of copper and her engines were of the ordinary side-lever type. Leaving Falmouth on March 16, 1837, she reached Bombay on June 13, having called at Santa Cruz, Mayo, Fernando Po, Table Bay and Port Louis. Her average speed was about 8 knots.

Therapeutic Use of Odours

AT a meeting of the Medico-Botanical Society on February 22, 1837, reported in the *Lancet* of March 4, Dr. George G. Sigmond read a paper on odours. Though not now used therapeutically, the older physicians employed them, and, according to Dr. Sigmond, they might once again be found of service in medicine. Travellers, he remarked, who sleep in houses made of cinchona wood, escape intermittent fever, probably from the odour of sulphate of quinine. A similar odour has also relieved tic douloureux. In a work published by a pupil of Linnæus after the death of that eminent botanist, who, however, superintended the construction of the volume, plants were divided into seven classes according to their smells as the *aromatica*, the *fragrantia*, etc., each odour having an action peculiar to itself, and some suggestions were made for imparting odours to scentless flowers through the roots, etc.

Davenport's Invention of an Electric Motor

ON February 25, 1837, Thomas Davenport (1802–51) secured a patent for an electric motor, the first of its kind taken out in the United States. Davenport was a blacksmith of Brandon, Vermont, who about 1833, with his friend Orange Smalley, began experimenting with magneto machines, unaware of what Henry had already accomplished. By December 1834 they had made a machine having twelve permanent magnets and two electromagnets connected through a form of commutator consisting of wires dipping into mercury cups to an electric battery. By May 1835 he had substituted for the mercury cups insulated segments on the lower part of the wheel shaft, which were rubbed by contact springs made of flattened wire. His new machine he showed to Henry at Princeton, and there saw Henry's own electromagnetic engine.

On Henry's advice, Davenport showed his machine to Alexander Bache and to a group of men at the Franklin Institute, but being short of money, sold it to the Rensselaer Polytechnic Institute for 30 dollars. Encouraged by Prof. Eaton, he made a new machine adapted for traction purposes, and this was exhibited at Troy on October 14, 1835. He was joined by Ransom Cook, and new models were built and exhibited, and Davenport lodged a model and applied for a patent, but at the Patent Office fire of December 15, 1836, both model and papers were destroyed. Soon after this, however, he secured his patent of February 28, 1837, and his model is now preserved in the National Museum at Washington. The inventor, however, reaped no reward for his ingenuity and died on July 6, 1851, on a small farm in Salisbury, Vermont.

Faraday on Marshall Hall

THE *Lancet* of February 25 contains the following note on a lecture delivered at the Royal Institution by Prof. Faraday on "Dr. Marshall Hall's Discoveries in the Nervous System": "The principal feature in these discoveries appears to be the fact that in the medulla oblongata and the spinal marrow resides a function which is distinct from sensation and volition, and termed by Dr. Hall the *reflex excito-motory function*, from its generally proceeding along the nerves from the point of excitement to the spinal marrow, and being reflected from thence to some muscular organ. For this reason the seat of this class of action is called by him the excito-motory system. Müller, of Berlin, Mr. Faraday stated, has in a remarkable manner confirmed the truth of Dr. Hall's discoveries by a recent and separate investigation, although the former still confounds the nature of the function with sensation. . . . Mr. Faraday concluded by observing that Dr. Hall's views are original, all preceding physiologists having confounded the phenomena alluded to with sensation. The subject appears to have interested Mr. Faraday, as not improbably preparing the way for some future discovery relating to electricity as connected with the nervous system; for, as he said, the division of the nervous system into distinct portions was somewhat simplifying any investigation with regard to electricity, considered as a nervous agent."

University Events

CAMBRIDGE.—G. E. Briggs, of St. John's College, has been appointed reader in plant physiology.

The Raymond Horton-Smith Prize awarded to that candidate for the degree of doctor of medicine who presents the best thesis for the degree during the year has been divided between Dr. F. Goldby, of Queens' College, and Dr. J. Gray.

Mr. Thomas Dalling has been elected to the professorship of animal pathology, in succession to Prof. J. B. Buxton, Queens' College, who resigned last term on being appointed principal of the Royal Veterinary College.

Dr. R. G. W. Norrish, formerly fellow of Emmanuel College, H. O. Jones lecturer in physical chemistry, has been elected to the professorship of physical chemistry vacant by the death of Prof. T. M. Lowry.

* * *

OXFORD.—The Herbert Spencer Lecture for 1937 will be given by Dr. Joseph Needham on May 27 at 5 p.m. in the Examination Schools. The subject is: "Integrative Levels, a Revaluation of the Idea of Progress".

Prof. The Svedberg, of Uppsala, will give two public lectures in English in the Museum, Oxford, at 5 p.m. on February 26 and 11.15 a.m. on February 27. The subject is: "Sedimentation, Diffusion and Electrophoresis Technique for the Study of High-Molecular Compounds".

Societies and Academies

London

Royal Society, February 11.

N. G. Heatley and P. E. Lindahl: Studies on the nature of the amphibian organization centre. (5) The distribution and nature of glycogen in the amphibian embryo. N. G. Heatley, C. H. Waddington and J. Needham: (6) Inductions by the evocator-glycogen complex in intact embryos and in ectoderm removed from the individuation-field. Total glycogen, lyo-glycogen and desmo-glycogen have been estimated by quantitative micro-chemical methods in the amphibian embryo around the gastrulation period. Prior to gastrulation, the glycogen concentration is highest at the animal, lowest at the vegetal, pole. During gastrulation, the total glycogen decreases in amount all over the embryo, but especially markedly (30 per cent) in the material which invaginates through the dorsal lip of the blastopore. Desmo-glycogen also decreases in all regions. It is thought unlikely that desmo-glycogen can be identical with that fraction of glycogen to which the evocator may be attached in the cells. The finding that both lyo-glycogen and desmo-glycogen preparations produce successful neural inductions in the chick embryo makes this still more unlikely. The distinction between evocation and individuation has been studied by implanting desmo-glycogen preparations (containing the adsorbed evocator) into isolated pieces of competent ectoderm. Massive neural inductions are produced, but these have not the character either of recognizable parts of the nervous system or of sections of a normal neural tube. On the other hand, the cells are not oriented entirely at random. This is believed to demonstrate the effect of the homogeneous stimulus of the primary evocator. Following on the induction of neural tissue in these explants, the repulsion of overlying ectoderm and the formation of melanophores were observed. These two effects are interpreted as dependent differentiations brought about by the presence of neural tissue as such.

A. Haddow and A. M. Robinson: The influence of various polycyclic hydrocarbons on the growth-rate of transplantable tumours. A. Haddow, C. M. Scott and J. D. Scott: The influence of certain carcinogenic and other hydrocarbons on body-growth of the rat. While intra-peritoneal administration of a number of carcinogenic hydrocarbons produced considerable inhibition in the rate of growth of the Jensen and Walker tumours, a series of related non-carcinogenic compounds gave no such inhibition. One synthetic œstrogen was moderately inhibitory and another quite inactive. Inhibitory activity was also shown to a variable extent by chrysene and by 1:2-benzanthracene and certain of its derivatives (3-, 4- and 7-methyl-), the carcinogenicity of which is either very feeble or nil. In comparative experiments on body-growth, X-radiation, lead, and colchicine were found to produce a temporary interference which was followed by recovery to the normal growth-rate, with or without compensation. Although the carcinogenic hydrocarbons must be regarded as toxic substances, their growth-inhibiting action is apparently independent of toxicity in any non-specific sense. The inhibition produced by the carcinogenic compounds was extremely prolonged, even after a single injection. There is thus a correlation in compounds of this type between carcinogenicity and growth-inhibitory power. The mode of action of these substances seems to be indirect; they operate by producing a prolonged retardation of the growth of normal cells, which eventually react by a process of discontinuous variation to give a new cell race with a greatly increased fission rate.

Paris

Academy of Sciences, January 18 (*C.R.*, 204, 161–200).

Léon Lecornu: Obituary notice of Joseph Auclair.

Gabriel Bertrand and Georges Brooks: The composition of the wood of the trunks and branches of the principal French trees. Determinations of xylose, mannose and cellulose.

Serge Finikoff: (T) Configurations admitting an infinity of Calapso transformations.

Douchan Avsec: The wave forms of vortices in longitudinal bands.

Jean Hély: A synthetic theory of gravitation and of electromagnetism.

Maurice Cotte: The convergence and achromatism of centred systems of electronic optics.

Pierre Jacquet: The application of electrolytic polishing to the study of metallic deposits. The crystalline nature of the supporting metal is destroyed by the usual mechanical polishing methods; but the electrolytic method recently suggested by the author gives smooth, brilliant surfaces without altering the structure of the underlying metal. Some experimental results with copper are described.

Salomon Rosenblum, Marcel Guillot and Mlle. Marguerite Perey: The α magnetic spectra in the actinium family.

Paul Bayard. The infra-red absorption spectrum and molecular structure of pyruvic acid. From the data given, it appears that pure pyruvic acid exists almost entirely in the ketonic form, but the presence of a band attributable to the (OH) vibration proves the existence of a certain proportion of the enolic form.

Paul Laffitte and André Parisot: The influence of the velocity of detonation of an explosive on the velocity of the shock wave. The results of experiments proving that the velocity of the explosive wave and that of the shock wave increase at first with the density of the charge. This disagrees with the results of Gawthrop, and possible causes for the difference are discussed.

Fernand Gallais: The constitution of solutions of potassium iodobismuthates. These solutions possess an exceptionally high magnetic rotatory power, and utilizing this property it was found that the chief complex ion in solutions of potassium iodobismuthate was either $(BiI_6)^{3-}$ or $(BiI_7)^{4-}$, and it was not possible to decide between the two formulæ. Compounds of both types have already been isolated.

Emile Thellier: The magnetization of baked clay: application to the study of the intensity of the earth's magnetic field in the past. A method is described for deducing the intensity of the earth's magnetic field at the time the brick was baked.

Jean Feldmann and Robert Lami: The marine vegetation of Guadeloupe.

C. Rizzo: Movements of teleosts in relation to experimental lesions of the peripheral apparatus of movement and of sensation (4). Labyrinthine lesions.

Sydney

Royal Society of New South Wales, October 7.

M. D. Garretty: Some notes on the physiography of the Lake George region, with special reference to the origin of Lake George.

G. J. Burrows and A. Lench: (1) The action of lead tetrachloride on primary and secondary halogenated arsines and on tertiary arsines. (2) Note on diphenyl dihydroxy arsonium chloride, $Ph_2As(OH)_2Cl$.

O. U. Vonwiller: Interference by reflection from a concave spherical mirror. Interference bands may be observed when light is reflected at large angles of incidence from a spherical concave mirror, the result of the superposition of beams which have undergone different numbers of reflections. Two, three or more beams may contribute. An examination is made of the conditions for the occurrence of the bands and of the ranges over which those due to particular pairs of beams are observed. The band interval for a given system is $a\lambda/\theta^2$, θ being the deviation of the light and a depending on the numbers of reflections of the two beams concerned. The factors controlling intensity are investigated. A convenient and reasonably accurate method for the determination of wave-length is based on the effect.

J. C. Earl and N. G. Hills: The action of nitrous acid on amines. A comparison has been made of the behaviour of aniline and methyl aniline, respectively, with nitrous acid. The possibilities of interference by secondary reactions in the case of aniline has to be kept in view. Allowing for this the experimental results recorded indicate that the reactions are essentially similar. Dilatometric and conductimetric methods were used in making the comparison.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, February 22

Victoria Institute, at 4.30.—Alan Stuart: "Science and the Interpretation of Scripture".

Bedford College for Women, at 5.15.—Dr. Friedrich Zeuner: "Some Aspects of Evolution revealed by the Study of Fossils".*

University of Leeds, at 5.15.—Prof. F. A. Lindemann, F.R.S.: "Low Temperature Research".*

Royal Geographical Society, at 8.30.—Eric Shipton: "More Explorations round Nanda Devi".

Tuesday, February 23

Warburg Institute, at 5.30.—Prof. J. Huizinga: "The Play Element in Culture".*

Wednesday, February 24

Society for the Study of Alchemy and Early Chemistry, at 8—(at University College, Gower Street, W.C.1).—Discussion on "Alchemical and Chemical Symbols".

Royal Society of Arts, at 8.15.—Prof. W. L. Bragg, F.R.S.: "Alloys".

Friday, February 26

Institution of Chemical Engineers, at 11 a.m.—Fifteenth Annual Corporate Meeting to be held at the Hotel Victoria, Northumberland Avenue, London, W.C.2.

Geophysical Discussion, at 4.30—(at the Royal Astronomical Society).—Discussion on "Radio Observations in High Latitudes" to be opened by Prof. E. V. Appleton, F.R.S.

University of Oxford, at 5—(in the Museum).—Prof. The Svedberg: "Sedimentation, Diffusion and Electrophoresis Technique for the Study of High-Molecular Compounds" (succeeding lecture on February 27 at 11.15 a.m.).*

British Psychological Society, at 8.30—(at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1).—Prof. T. H. Pear: "Psychological Problems of Television".

Royal Institution, at 9.—Lord Horder: "Old Diseases and New".

Association of Technical Institutions, February 26–27.—Annual General Meeting to be held in the Carpenters' Hall, Throgmorton Avenue, London, E.C.2.

February 26, at 10.45.—The Right Hon. Lord Kennet: Presidential Address.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant in Mathematics and Engineering Science and Assistant in Electrical Engineering in the Willesden Technical College—The Secretary, Willesden Local Higher Education Committee, Education Offices, Dyne Road, Kilburn, N.W.6 (February 26).

Scientific Officer (Ballistic Problems) in the Air Ministry—The Secretary, Air Ministry S.2.D., Adastral House, Kingsway, W.C.2. Quote No. B348) (February 26).

Lecturer in Chemistry in the Wigan and District Mining Technical College—The Principal (February 27).

Inspector of Mines, Burma—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (February 27).

Senior Agricultural Advisory Officer for West Norfolk—The Director of Agricultural Education, Agricultural Station Offices, Sprowston, Norwich (February 27).

Pharmacist in Runwell Hospital, near Wickford, Essex—The Clerk to the Visiting Committee (February 27)

Government Chemist, Cyprus—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, London, S.W.1 (March 6).

Assistant Lecturer in Mathematics and Assistant Lecturer in Zoology in University College, Exeter—The Registrar (March 6).

X-Ray and Radium Physicist in the National Research Council of Canada—The Secretary, National Research Council, Ottawa (March 15).

Professor of Physiology in the Lady Hardinge Medical College, New Delhi, India—The Principal (April 15).

Lecturer in Domestic Science in the Gloucestershire Training College of Domestic Science, Barrack Square, Gloucester—The Secretary.

Conservation of Buildings and Landscape

THE discussion which took place in the House of Commons on February 10 on the motion of Mr. A. C. Bossom, member for Maidstone, on the destruction of beauty in town and country and of buildings of historical or architectural interest now proceeding in Britain, evoked a striking unanimity in expression of opinion from all sides. The motion had not only called upon the House to deplore the present situation and to agree as to its urgency; but it had also pressed upon the Government the need for active steps to ascertain "whether its existing powers are adequate, or whether they require substantial reinforcement". No voice was raised to repudiate responsibility, or to deny that this destruction was in the least degree anything but a serious matter of public concern; while in the final result the motion was adopted by the Government, and an inquiry promised.

In the course of the debate, it became evident that there was a general consensus of opinion that control of development, in so far as it affects the beauty of rural Britain, the preservation of structures of historic interest in a broad sense, and the protection of buildings and landscape from grossly incongruous structural associations, is in present conditions a national duty and not merely a matter of a local sense of responsibility. This also was the view, it may be mentioned incidentally, strongly urged by Sir Halford Mackinder and Sir Percy Hurd before the Council for the Preservation of Rural England on the following day.

While the House of Commons paid well-deserved tribute to the success of the Office of Works in carrying out its duties in the protection of ancient and historic monuments with the exiguous resources at its disposal, it was pointed out in debate that in the most extensive field of its operations, that of the inhabited house, its powers are restricted, and that here even more than elsewhere, its activities are impaired by lack of funds.

The inhabited house has always presented a difficult problem in this connexion. To a certain extent, no doubt, shortcomings in the action now open to public authority will be met by the legislation to be introduced on behalf of the National Trust, to which reference was made in the reply for the Government by Mr. R. S. Hudson, Parliamentary Secretary of the Ministry of Health, accompanied by an assurance of the good will and sympathy of the Ministry of Health, the Office of Works and the Treasury. The scheme, however, for which powers will be sought, as it is understood, will apply in the main to the larger and more important examples of domestic architecture, and will be of little avail for structures of lesser pretensions and the villages typical of rural Britain in its varied cultural phases, for which Mr. Marshall, member for Sheffield, stressed the importance of preservation, as a unitary whole, as examples of "an architecture wedded to the landscape in which it is situated", each of a type and characteristics peculiar to its environment.

The problem of preserving these humbler structures should not be insuperable. Recent experience in reconditioning has shown how far villages, in which buildings have already been or are about to be condemned, may be preserved at a reasonable charge, and that whole villages need not necessarily be radically changed in character or ruthlessly spoiled on a demand for sanitary reform, which is blind to all considerations but one, important as that may be. The ways of the county surveyor and the rural district council, however familiar, never cease to seem wonderful. Even in urban conditions where the call for improvement may be more insistent and financial considerations more difficult to meet, it may yet be possible to preserve historical and cultural associations, other things being equal, by the application of modern methods of reconditioning.

Of the two factors, lack of interest or knowledge and finance, which enter into the problem and appeared to weigh most with members of the House as insistently demanding the intervention of central authority, the latter, finance, demands by far the more drastic treatment. As Mr. Hudson pointed out in his reply, and as was mentioned by other speakers, training and knowledge are, or can be made, readily available for the advice of local authorities. Yet while it is true that there are numerous local societies—field clubs, natural history societies and archæological societies—distributed up and down the country, of which the members are fully competent, as the Parliamentary Secretary suggested, to educate their neighbours, anyone who is acquainted with actual conditions is well aware that the standing of these societies and the influence which they can bring to bear when action is contemplated in any given instance, varies enormously from one locality to another. The expression of instructed opinion available in these bodies needs to be co-ordinated and disseminated in such a manner that its weight will receive due recognition. For such an organized expression of opinion the machinery already exists in the various associations and federations in which these societies combine for the discussion of common interests. In certain directions and on occasion, common action is taken, at times with conspicuous success. More systematic organization with the specific needs of the present situation in view is required.

Further, would it be too much to ask, failing a systematic survey and enumeration of ancient and historic structures worthy of preservation, such as has been carried out by the Surrey County Council, and is, it is stated, to be urged on other authorities, that each town-planning scheme should include a clause safe-guarding such structures? Such a clause would show that an authoritative opinion had been obtained that no building of historic or æsthetic interest and importance had been marked for demolition, or, if any such there were, a reasoned justification for its destruction would be put forward for consideration and decision by central authority.

It is questionable if even this goes far enough. Excellent though the work of the Council for the Preservation of Rural England and similar organizations may be in creating a public sense of responsibility, no unofficial body, can view conditions so comprehensively, or speak with the authority of a central body or department, with powers delegated from the people as a whole.

Finance is obviously the real crux of the problem. Upon whom is the expense of conservation to fall? Even under existing legislation, the powers of a local authority are considerable, though, it may seem unfortunately, permissive only. The town-planning acts make it possible for the authority to intervene—but do not require that it must intervene—when the demolition of a structure of historic interest is contemplated. At once there arises the question of compensation, with all the possibilities of abuse. Nor is it practical to expect that an authority with only a low rateable value upon which to draw, will contemplate action entailing heavy expenditure, whether for purchase or compensation, with an entirely open mind. At the same time, to brand indiscriminately development of land or an urban site as merely personal greed, because such development conflicts with æsthetic ideals or archæological and historical interest, is to invite derision from those whose co-operation it is desirable to enlist.

Each instance must be judged on its own merits; and the arguments which weigh for conservation should help to determine where the financial burden should fall. When national considerations determine the issue—and this must cover the claims of associations bound up with the nation's history at large—or matters of wide general interest in the scientific pursuit of archæological and historical studies, as in the instances of the Roman Wall and the country around Stonehenge and Avebury, the burden of conservation is one which should fall on the nation's purse. A scale of grants might well be devised for the assistance of local funds, when interests more restricted in range, but nevertheless of historic, scientific or æsthetic weight, are involved and public action is demanded. On the broad issue, however, the principle should stand. As Sir Halford Mackinder said on the occasion to which reference has already been made, we and the countryside have grown together; the loss of its beauty would be the loss of half of ourselves; and its protection should be a national charge.

The Fullness of Days

My Fill of Days
By Sir Peter Chalmers Mitchell. Pp. 440. (London: Faber and Faber, Ltd., 1937.) 15*s*. net.

THE modern practice of using single words, or fragmentary sentences, bearing little or no relation to the subject-matter, as the titles, not only of novels—where it is excusable—but even of important biographical works, will undoubtedly cause much embarrassment, and even loss, to the historian and bibliographer of the future; but if ever such a title was justified, it is justified by the absorbingly interesting volume before us. It may be said at once that no man has ever lived, the fullness of whose days has been more striking and complete than those of Sir Peter Chalmers Mitchell, from the time that he made fireworks and other scientific experiments as a schoolboy, until he left the smoking ruins of Málaga, on a British destroyer on February 11, 1937. Chalmers Mitchell is a man devoid of fear—though perhaps, to quote Dr. Johnson, he never snuffed a candle with his fingers—but probably the boldest, one might say the most foolhardy event of his life, was his return to Málaga immediately after the publication of this volume, in which he gives a vivid account of Málaga in 1936 (chap. xx) and makes no concealment of his attachment to the so-called Red (Government) régime, and his activities in protecting and assisting the escape of 'Red' proscripts. What emerges most significantly from this book for 'the eye of wisdom' is a side of the author known only to his most intimate friends He reveals himself here as a poet and as an artist, capable of warm-hearted and disinterested sympathies for the oppressed, and a loving and lovable nature—rarely to be found in those who, like him, are actively disinclined to the suffering of fools gladly—as recommended by St. Paul.

Chalmers Mitchell's descriptions of scenery, for example, of the Biscayan coast, of Montpellier, and of Arles, to quote but three vivid passages, are the unconscious work of both poet and artist, nor are his pen-pictures of the celebrated men who have been his friends and colleagues, to name but a few out of very many, Ramsay, Clemenceau, Ruskin, Freeman, Minchin, Ray Lankester and Burdon Sanderson, less striking and exact—as the present reviewer, having personally known most of the subjects of his pen-portraits, is in a position to appreciate. Equal in quality and charm is his description of Oxford and its influence upon the adolescent mind, a description that will awaken echoes in the mind of every whilom undergraduate.

It is interesting to note the record that the author narrowly escaped being a son of Sir Archibald Geikie, in which case the world might have honoured a great geologist, instead of a zoologist of world-wide reputation. It is a task of extreme difficulty to pick out the salient features of a book, almost every paragraph of which arrests the attention of the reviewer, for the author writes as he talks—or lectures—in a style that is incisive and arresting, interspersed with sly flashes of humour which no Scotsman would resent being described as 'pawky'. The plan of his idealized Zoological Gardens may be said to have originated in the 'Zoo' at Hamburg, long before the days of Hagenbeck, who later became an intimate friend, adviser and colleague. At this period, he heard in Berlin the first indication of Bismarck's *Weltpolitik* (in 1884), and in that connexion we get here a lucid statement and study of the inter-relations of Great Britain and Germany He has saved from oblivion, in these pages, his article published in the *Saturday Review* (Feb. 9, 1896) entitled "A Biological View of Our Foreign Policy", in which the cataclysm of 1914–18 is soundly and clearly adumbrated.

Valuable advice is given to lecturers, founded upon the author's own vast experience, and no one who has delivered a Friday evening discourse at the Royal Institution will fail to appreciate sympathetically his mental reactions when undergoing that terrifying experience. His first enforced plunge into the science of accountancy (p. 100 ff.) sheds a significant light on the mastery of finance which he unexpectedly displayed when he became secretary of the Zoological Society.

The pages devoted to 'Weissmannism' are lucid and instructive; and it is amply apparent to what an extent his friendship with Hagenbeck encouraged him in the reform of the old Zoological Gardens, and in his views upon the treatment of animals in captivity, which led to the crowning episode of his life, the establishment of Whipsnade, the history of which must fascinate any zoologist.

The author is usefully polyglot, and he lays stress upon the influences of French literature, though doubtless many critics would meet him in the gate when he sandwiches Octave Mirbeau between Zola and Anatole France. His almost lifelong industry as a journalist has been amazing. He has been a prolific leader writer in the *Saturday*

Review, in NATURE and, above all, on the staff of *The Times*, all of which led to the important part that he played at the Ministry of Intelligence and Propaganda during the Great War, and especially to his attempted flight from Cairo to the Cape, which, from circumstances over which he had no control, may be described as a brilliant and useful failure. His description of this journey as a scientific spectator reads like an adventure story, and occupies some seventy pages of this remarkable book.

We have already referred to Chalmers Mitchell's vivid picture of Málaga in 1936, a description for which we were prepared by his long account of the conditions existing there, published in *The Times* (October 20, 1936). Where one must, we think, accuse him of hasty judgment is where he connotes brains and ill-health. He says (p. 209): "I cannot recall . . . any person greatly distinguished by the product of his brain, who was a type of good health." We would answer this blazing generalization with the question: "What about Peter Chalmers Mitchell ?"

The Epilogue will be read with close attention and with very varied reactions by a vast number of readers. The author is a convinced, almost a militant, Communist. It cannot fail to arouse the interest and the regretful appreciation of the most hardened Conservative. If only his gospel were in any degree credible the world would be profoundly modified—whether for better or for worse is a controversial matter. One may, we think, fairly say that the Epilogue is the dream of a Communist poet, crystallized—and beautifully crystallized—into a politico-utopian creed suitable for an Ideal Commonwealth.

Electron Theory of Metals

The Theory of the Properties of Metals and Alloys
By Prof. N. F. Mott and Dr. H. Jones. (International Series of Monographs on Physics.) Pp. xiii+326. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 25*s*. net.

THE great interest with which the electron theory of metals has been received by physicists is due chiefly to two reasons. The first is the practical importance of metals and their great variety, enhanced by the possibility of alloying different metals. Thus a large amount of experimental data has been collected, and offers an extensive field for theoretical investigation which, in its turn, will be helpful from the practical point of view as a guide for the classification and discussion of the material.

The second reason lies in the fact that, before quantum mechanics, metals represented one of the greatest puzzles of theoretical physics. At a time when the properties of atoms, the structure of ionic crystals, etc., were at least qualitatively understood, any attempt to explain the behaviour of electrons in metals landed one in hopeless contradictions. Therefore it was natural that when the papers of Fermi, Pauli and Sommerfeld showed that the difficulties could be overcome with the aid of quantum mechanics, the centre of interest in the theory of metals lay in these difficulties and their removal. One saw how Fermi's statistics reconciled the absence of a high specific heat of the conduction electrons with their large contributions to electric and thermal conductivity, and how the wave nature of the electron reconciled the strong forces acting on the electrons with a mean free path greatly exceeding the atomic distance. There was a large number of similar questions, all concerning the properties of metals *as a class*. During that time the other aspect of the theory of metals, the discussion of the differences between *individual* metals and the relations between the properties of any one metal, was neglected.

This group of problems has been attacked only in the last few years in a number of papers, among which those of the Bristol workers are of outstanding importance. In the excellent account they give in a new volume of the "International Series of Monographs on Physics", Prof. N. F. Mott and Dr. H. Jones very rightly emphasize this second point of view, and indeed theirs is the first book on metal theory in which the properties of individual metals are reliably discussed and explained. At the same time they do not neglect the other aspect of the subject, and give a good introduction to the general foundations of the theory of metals.

The work which they discuss, and the many original contributions to the subject they have made in the course of preparing the book, are with few exceptions based on the picture of one electron moving in a field of force. In other words, the correlation between different electrons is neglected or at least greatly simplified. This limitation is customary in the theory of metals, and is imposed by the need of avoiding mathematical complications which nobody has yet been able to overcome and which are not likely to be overcome in the near future. This 'one-electron approximation' results in a slight uncertainty in the predictions of the theory; it is most probably responsible for the failure of the theory to account for supraconductivity. The authors point out clearly where use has been made of this simplification, and which results may possibly be affected by it. One would thus not be surprised if the results agreed with the experimental evidence less well than they actually do; they seem to confirm a general rule—very comforting to the theoretical physicist—that "every approximation gives better results than it might do".

It is, of course, not possible here to give a complete list of the problems dealt with in the book, but they include a thorough discussion of the structure and the thermal, optical, magnetic and electric properties of metals. Surface phenomena, such as the thermionic emission and the photo-electric effect, are wisely omitted. Also electron diffraction is not mentioned—which is perhaps a pity, since it would have been instructive in connexion with the 'zone structure' of the electronic levels inside a metal.

On all these problems, the theoretical situation is reviewed and the empirical constants are related to the fundamental constants of the metal in question, or, as in the case of the cohesion forces and the elastic constants and the specific heat at low temperatures, calculated on purely theoretical grounds. Then the experimental data are reviewed in the light of the theoretical results.

Every mathematical proof is preceded by a short qualitative argument showing its main points, and in this way the important steps remain clear to a reader who does not want to follow the formal argument in detail. This, together with frequent cross-references and a large number of diagrams and tables, makes the book also very handy for reference to special points.

It need scarcely be said that the exposition is as clear and the mathematical treatment as simple and reliable as we have become used to expect of a book that bears Prof. Mott's name. R. P.

Reinforced Concrete

(1) Principles of Plain and Reinforced Concrete Construction

By Dr. E. Probst. Pp. xii+344. (London: Edward Arnold and Co., 1936.) 30*s*. net.

(2) Elementary Structural Problems in Steel and Timber

By Prof. C. R. Young. Second edition. Pp. xiii+315. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935). 20*s*. net.

(3) Architectural Graphic Standards:

for Architects, Engineers, Decorators, Builders and Draftsmen. By Charles George Ramsey and Harold Reeve Sleeper. Second edition. Pp. xii+284. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 30*s*. net.

(1) FOR a number of years, as professor and director of the Concrete Laboratory, Karlsruhe, as a private investigator in his own laboratory and as a practising engineer, Dr. E. Probst has studied the use of concrete, its properties and its possibilities, and the results and conclusions arising out of this work have recently been published. In the English translation, "Principles of Plain and Reinforced Concrete Construction", for which the author accepts responsibility and which may therefore be taken as authoritative, his investigations have been described and explained in an easy style and in full accord with English nomenclature and units, the notation and symbols being those adopted in the Report of the Reinforced Concrete Structures Committee (Department of Scientific and Industrial Research).

Dr. Probst takes the view that, in general, the solutions of the unexplained problems of concrete construction are to be obtained from a study of the material itself, not as an idealized structural material constituted according to preconceived theories and more or less dissociated from the purpose for which it is required, but with the steady aim of bringing design, calculation and execution into harmony with the peculiar and individual properties which the material can be shown to possess. With this purpose, the author first examines the plain concrete, noting the properties of the various cements and aggregates used and discussing their testing, grading and mixing, and the physical and chemical properties of the mortars and concretes which they can be made to form. Relative to the influences of different qualities and proportions of the materials used, of shape, of methods of curing and other causes on the final result, extensive data have been collected and explained, and suggestions given as to those most suitable for particular conditions. Passing lightly over the subject of the qualities and forms of steel in use, the author treats at length the combination of concrete and steel, citing the results of numerous tests and observations and, in addition, examining the effects of ageing, heat, electric currents and chemical action.

In the second part of the volume, the statics of reinforced concrete structures are discussed and elaborated in relation to cases of axial tension and compression and to those of bending, and the calculation of normal and shear stresses in reinforced concrete sections is explained. The internal stresses at various periods after placing and those due to repeated loading are closely examined, and are shown to differ appreciably from the previously assumed modes of distribution, thus suggesting the need for revised methods of calculation such as are here exhibited. By means of a number of examples it is shown how the equations deduced in this investigation can be applied in simple designs.

(2) Prof. Young's book, in its second edition, contains many new problems involving the design of entire structures or portions of structures in addition to all the original material which is not out-dated by present-day methods. It is, in the main, concerned with the design of steelwork in buildings, bridge spans and cranes and also gives a substantial section to timber beams, trestles and roofs. The new material introduced includes welded connexions, a floor panel using reinforced concrete joists, and several other typically modern examples.

(3) "Architectural Graphic Standards" is an encyclopædia, wholly in the form of drawings, of building construction, fittings and furnishings, and gives the usual sizes of practically every item of which an architect is likely to require data. Here also reinforced concrete is largely represented in the new matter introduced.

Zulu Society

The Social System of the Zulus

By Eileen Jensen Krige. Pp. xix +420 +12 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd.; Johannesburg: University of the Witwatersrand, 1936.) 25*s*. net.

FOR several reasons the Zulus were for long, to the British public, the typical and, notwithstanding the eccentricities of Bushmen and Hottentot, the best-known of the indigenous peoples of South Africa. Their highly organized society and their resistance to British arms, especially at Rorke's Drift in 1879, made a deep impression on the popular imagination. The high estimate of Zulu character to which this gave rise found confirmation in the fiction of Rider Haggard. Further knowledge of the number of distinct peoples to be found in South Africa and of their marked differences has not entirely obliterated the impression.

Miss Krige's account of Zulu society, though not a comparative study, gives the English public a fuller and more comprehensive picture of its essential and distinctive features than has as yet been available within the compass of a single volume. For the anthropologist she has provided an invaluable summary of previous records, classified, digested and interpreted in the light of personal investigation among the people as they are to-day. Obscurities, omissions and doubtful points have been cleared up by inquiry from those among the people themselves who are reputed to be best acquainted with tradition.

As with other native peoples of South Africa, the place of origin of the Zulu is unknown, the attribution to West Africa, which has been favoured, resting on an early Portuguese inference of little value. Their traditions suggest that they were in South Africa in the sixteenth century. The crucial period of Zulu history, however, and their dominance among South African tribes, lies in the nineteenth century. In the early years of that century, Shaka acceded to power as king, and moulded his people into a fighting unit, organized into regiments, which maintained its independence until the fall of Cetewayo in the Zulu War of 1879.

Shaka was a man of strong and ruthless character, possessed of a genius for political organization, such indeed as is not without parallel in African history, but in his instance of an exceptional order. The consolidation of the Zulu people and the extension of their power was coupled with the rise of the Matabili and other movements of peoples, which affected tribal distributions so far north as Lake Nyasa. It was not unique. Similar consolidations appear to have taken place elsewhere in Africa at about the same time, or not long after. In the present state of African research, the predisposing conditions are not clear. Similarly, the regimental organization was based on the advantage taken of the age classes common to most Bantu peoples. In these and other details of Zulu organization, Shaka showed his outstanding ability by bending them to serve his purpose of Zulu supremacy and his own personal dominance. Obviously Zulu history is not without its lessons for to-day, when it thus demonstrates the political capacities and social adaptability of the African along lines congenial to his traditions.

This and like reflections must occur to any reader interested in the African, who takes Miss Krige's book in hand. Such broader implications of the theme lie beyond her scope; but she sketches the history of the Zulu people adequately to show its bearing on the development of Zulu society. Much of the old military organization, such as the regiments, survives, although it has lost its military purpose and meaning; and checks and counter-checks devised to consolidate Shaka's power, as for example in overriding the witch-finder, are still operative.

The Nile

The Nile:
the Life-Story of a River; from the Source to Egypt. By Emil Ludwig. Translated by Mary H. Lindsay. Pp. 352 + 34 plates. (London: George Allen and Unwin, Ltd., 1936.) 16*s*. net.

IN this book a famous biographer has attempted to give a description of the course of the Nile from its sources to the sea as if it were the life-history of a person. In it the reader with no first-hand knowledge will find much interesting information about the topography, vegetation, human and animal life, and history of the Nile basin, and may think that he is reading an authoritative work by one who has seriously studied the river and travelled extensively in its basin. If, however, he is sufficiently interested to pursue the subject further and refers to standard works, his confidence in the author will be badly shaken by the many mistakes which he will discover. The book is written in flowery language, and the reader will become very weary of the personality device and its meaningless symbolism before he comes to the end.

The first portion of the book is concerned with the great Lakes Victoria and Albert and the surrounding country in which the White Nile has its sources. Some of the information produced about the region is a little surprising, as for example the natural bridge at Nimule, "such as hardly another river on earth possesses in this form, consisting of rank water plants, so strong that it bears the elephant from one bank to the other, and so powerfully rooted that when floods have destroyed it, it closes up again of itself". Nobody else has ever reported this bridge, and as an elephant weighs five tons or more, the rank water plants must have been considerable trees. Some of the remarks about evaporation are equally strange, for the author says: "As Lake Victoria is not three hundred feet deep, so that more water evaporates than is received, this constant diminution, as we shall see later, presents the Nile engineers with a very grave problem." This is an example of the lack of knowledge of the elements of natural science displayed in the book and of the inaccuracies which are of frequent occurrence. Lake Victoria has not progressively diminished in volume in the forty years over which records extend, though, like other large lakes, it has fluctuated with the variations of the rainfall.

The author continues his description of the White Nile and then describes the Blue Nile and the Atbara, with some account of the history of Abyssinia, and the Main Nile as far as Aswan, the description of Egypt being left for a second volume. Towards the end of the book he has a few paragraphs on hydrology in which he gives some figures about the volumes of water flowing in the various tributaries. As many of these figures are badly wrong, it would have been better to have omitted them.

The remarkable feature about the book is the number of errors it contains. Some, like the picture of hippopotami entitled "rhinoceros" and the statements that the hippopotamus has been seen starving to death on phantom islands of grass, and that the Atbara rises in Lake Tana, will be readily detected; others, like the statistical errors, of which there are so many, will escape the notice of the general reader and be assimilated and perpetuated, for a false statement once started can never be overtaken. The most reliable feature of the book is the maps, which are taken from another work.

It is a misfortune that a book which is written by a well-known author should be so unreliable; but in a serious description of natural phenomena there is no excuse for gross inaccuracies, and the author owes it to his own reputation as well as to his readers to make no mistakes in his presentation of facts. Perhaps the lesson may be drawn that literary ability will not make up for lack of knowledge of the subject, and we recommend this consideration to the author before he produces the second volume of the work.

H. E. HURST.

Differential and Integral Calculus

By Prof. R. Courant. Translated by Prof. J. E. McShane. Vol. 2. Pp. x+682. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1936.) 30*s*. net.

THE English edition of Vol. 1 of this work was briefly reviewed in NATURE of March 9, 1935, and the present volume is a translation, also by Prof. McShane, of the original German text which was published in Berlin in 1929. It is devoted to the more advanced parts of the calculus; chiefly to functions of several variables and their physical significance. As in the case of vol 1, this edition differs in several respects from the German. It is indeed a much larger book, for there were only 360 pages in the original. Considerable additions have therefore been made, consisting mainly of an extended chapter on differential equations; new chapters on the calculus of variations and on the complex variable, whilst a supplement on real numbers and the concept of limit has been provided at the end. It may be remarked that it seems somewhat strange that the text of a modern book on advanced calculus should have to be amplified by a treatment of the complex variable.

The course, introduced by a chapter on the fundamentals of analytical geometry and vector analysis, embraces the usual topics generally considered as advanced calculus—derivatives of functions of several variables; multiple, line and surface integrals with the theorems of Gauss, Green and Stokes; differential equations with special reference to mechanical and physical problems, etc. Chapters ii–v are each followed by a useful appendix in which the relevant theory is further elaborated.

The needs of the student are well provided for, as the book not only abounds in copious exercises, but also devotes fifty-five pages at the end to answers and helpful hints. Mention should likewise be made of the very full and valuable summary of important theorems and formulæ. The text is well developed, clearly illustrated and excellently printed.

F. G. W. B.

The Birds of Tropical West Africa:

with Special Reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria. By D. A. Bannerman. (Published under the authority of the Secretary of State for the Colonies.) Vol. 4. Pp. xl+459+14 plates. (London: Crown Agents for the Colonies, 1936.) 22*s*. 6*d*.

THE publication of Mr. Bannerman's six-volume work on West African birds has been suspended midway for nearly three years, owing to financial exigencies of the times which have affected the Colonial Governments supporting it. Happily, these difficulties have now been surmounted, and with the appearance of this volume there is prospect of the early completion of a valuable record which should place the ornithological study of the region in a strong position. The book, it may be repeated, admirably serves the double purpose of a summary of existing knowledge and an aid to further investigation. In the latter respect, great pains have been taken to assist the observer in identification. As well as the detailed description of each form, there is at the beginning of the volume an illustrated key to the families and genera, and there is also for each family a further key to the genera and species. This useful feature was included in the earlier volumes, but it is especially welcome now that Mr. Bannerman is dealing with the huge and difficult order Passeres, the treatment of which will occupy the whole of the second half of his great work. In addition to text figures, the fourteen coloured plates beautifully depict sixty-five different species.

The Modern Dowser:

a Guide to the use of the Divining Rod and Pendulum. By Le Vicomte Henry de France. Translated by A. H. Bell. Pp. xvii+139. (London: G. Bell and Sons, Ltd., 1936.) 4*s*. 6*d*. net.

THE subject of dowsing is one to which a great deal of attention has been given in France in recent years, and its range of application has been extended in many directions, chiefly in the field of biology and medicine. This little book gives an excellent summary of the main facts, but its chief value lies in the instructions given which enable the reader to experiment for himself. Contrary to the practice of most of the best English dowsers, the author makes great use of the pendulum, and most of the instructions refer to this rather than the rod. As is usual in books on this subject, the physical explanation given could not be accepted by physicists in the form in which it is given, and when the author's account of the claims with regard to distinguishing wines, finding aeroplanes, and diagnosing disease are examined, the scientific imagination is stretched to the limit. However, there is no doubt of the enthusiasm with which the study of this curious, and in some sense genuine, human faculty is being carried on in France, and it is to be hoped that further experiment will throw some light on its physical nature.

Inorganic Preparations:

a Systematic Course of Experiments. By Alexander King. Pp. xi+164. (London: Thomas Murby and Co.; New York: D. Van Nostrand Co., 1936.) 5*s*. 6*d*. net.

THE present book contains detailed descriptions of 187 preparations, and sketches of almost as many additional preparations. The accounts of the experiments are sufficiently detailed to ensure success, and references to the literature are given. The text is arranged under the headings: physical state, elements, binary compounds, acids, bases and salts, complex salts, compounds of some rarer elements, and reactions which form the basis of some industrial processes. Many of the experiments are suitable for pupils in schools and the more difficult ones for university courses. They will form a valuable supplement to the courses in analysis, which fail to teach many important aspects of laboratory manipulation. The book may be warmly recommended, and it deserves to be widely used.

The Percy Sladen Expedition to Lake Titicaca, South America

By Prof. J. Stanley Gardiner, F.R.S.

AT the International Geographical Congress held at Cambridge in 1928, Mr. Hope-Jones and Major Vallenas, representing the Sociedad Geografica de Lima, suggested that a British expedition be arranged for the investigation of Lake Titicaca in all its aspects, and proffered the support of their Society. Owing to financial conditions in Great Britain, the contemplation of such an expedition was not possible then or for some years. Finally, in January 1936, the matter was referred to the Percy Sladen Trustees, who decided to send an expedition to work on the lake during the winter or dry season (April–October) of the present year, the proposed researches meeting with the complete approval of the Royal Society and the Trustees of the British Museum. The expedition is also receiving a generous welcome from the Peruvian and Bolivian Governments.

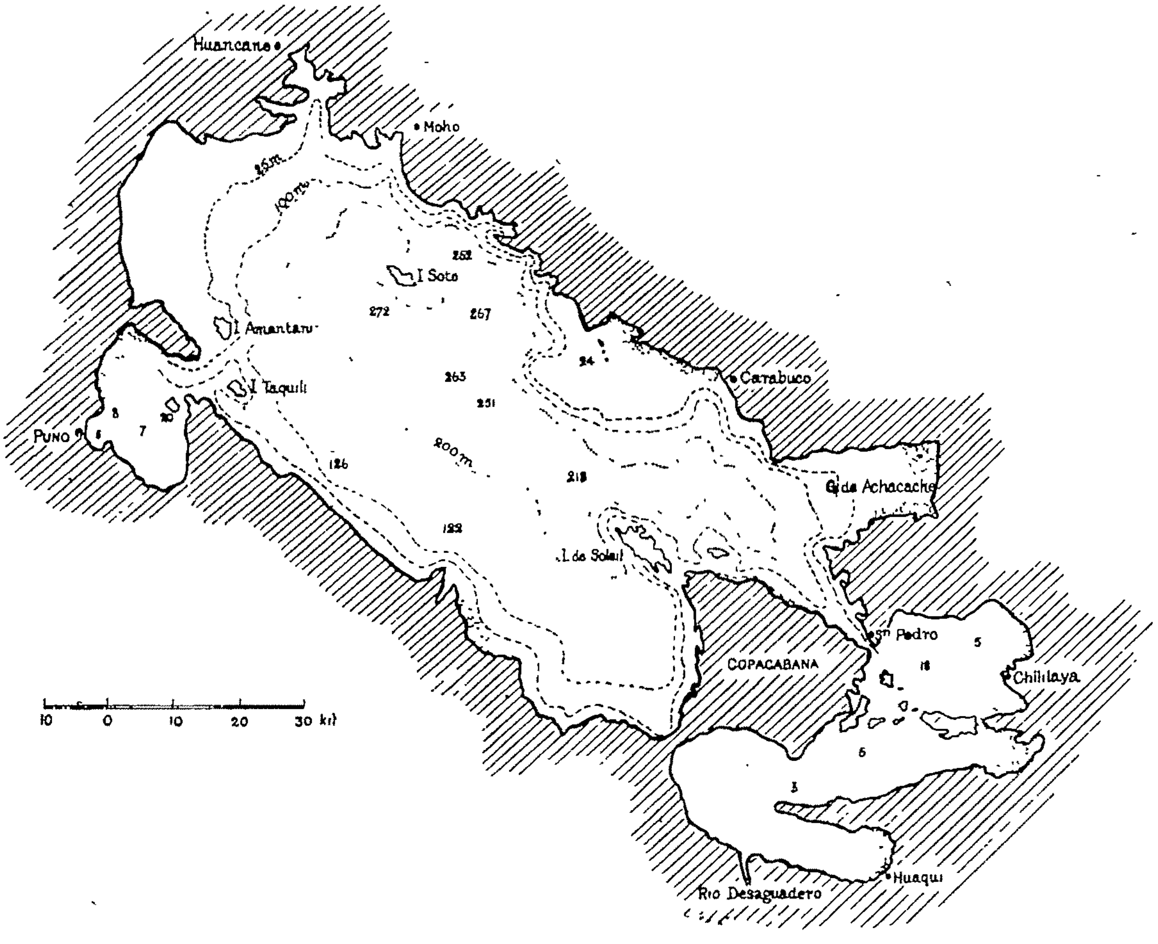

Fig. 1.
Lake Titicaca.

Lake Titicaca is situated in an area in the middle of the Andes, where these mountains branch and afterwards rejoin, and about two thirds of the lake are in Peru and a third in Bolivia. It is situated at 12,500 ft. above sea-level and covers more than 3,000 square miles, its deepest sounding at present being 273 metres. It is fed mainly by streams from the mountains, which attain a height of 22,000 ft. to the east, while the railway pass from Molliendo to the west is at 14,666 ft., the total area of this central plain being more than 100,000 square miles. The lake itself is subject to differences in level of its waters, the causes of which are not clear, since it has an outflow by the Rio Desaguadero to the shallow Lake Poopo, about 300 miles to the south. Around this is a large area of partially overgrown marsh, into which there is extensive seepage from Poopo, the whole plain having no communication on any side with the sea. On Lake Titicaca the nights are cool, often with ground frost, but the days frequently experience a temperature range of 60°–70° F. However, the temperature of the lake remains relatively constant, perhaps due to the strong winds along its length from south to north causing mixation of its waters.

The country around, almost certainly the original home from which potatoes were imported into Europe, is for the most part dry and bare of timber. It is approached by the Southern Railway of Peru, the main line of which extends north to the Cuzco region, the central part of the Inca Empire. Around it are lead and other mines, and the Peruvian Corporation, which has most generously extended its help to the Expedition, besides managing the railway and conducting business enterprises, runs a regular steamer service from Puno in Peru, a town of more than 20,000 inhabitants, to Huaqui in Bolivia. Around the lake are a few small settlements, and the Island of the Sun in the Bolivian area is the centre of an important pilgrimage.

The lake itself is evidently little affected by drainage from settlements, and agriculture in its surrounding lands is little developed. It indeed seems to be fed mainly by glacier streams of relatively constant volume and composition. It was visited by Alexander Agassiz sixty years ago, when a few amphibians, two genera of fish and some higher crustaceans were obtained. Its birds were collected by an expedition from the American Museum, and lately there has been an investigation of its biology with the view of introducing more profitable fish, as has been done into some northern Peruvian lakes. Apart from the fauna and flora, the full range of which will have to be ascertained, the lake presents a unique field for ecological study Its position suggests that it is a relatively primitive lake, and it may well belong to an 'oligotrophic' type, in contrast to the 'eutrophic' lakes of the East Indies and Central Africa. In this connexion, the question of its nitrogen cycle will be a main object of interest, the distribution of nitrates, nitrites, ammonia and organic nitrogen, the seasonal changes in the same at various depths to determine their transformations ; such researches, perhaps owing to a certain simplicity in the lake, should form invaluable data for comparison with the more complicated phenomena of the sea. Simultaneous determinations will have to be made of the quantity, composition and distribution of the plankton, which is as yet unknown. To obtain an understanding here will necessitate *p*H, oxygen, phosphate and other analyses. Further, the fauna and flora of the shallow waters of its long coast-line will have to be surveyed adequately and ecologically.

On the physical side, here is a lake with the sea-level pressure reduced to two thirds with consequent effects on wind-force. The solar radiation is greatly increased, especially at the ultra-violet end of the spectrum, which has particular biological significance. Here are two matters of which relatively little is known, and on which it is hoped that results may be obtained that will elucidate conditions in low-lying lakes. Measurements of light penetration are desirable to determine the limits in depth to which the phytoplankton can flourish. These are special subjects in the general hydrographical study of the lake and of its circulation as revealed by temperature and density observations.

The expedition as now arranged is under the leadership of H. C. Gilson, fellow of Trinity College, Cambridge, who will be accompanied by T. G. Tutin as botanist, H. P. Moon, G. I. Crawford of the British Museum, P. F. Holmes and D. M. Hall. All are graduates of the University of Cambridge, relatively young, because at these altitudes no others can, without long acclimatization, be expected to carry on the constant labour that the expedition will entail, and because to the optimism of such must be assigned the scientific attack in new directions, for which they have now been preparing for many months. They are to be joined by Dr. H. E. Hinton as a volunteer, his study being the water-living insects of the lake and streams.

The expedition leaves England on March 11, Messrs. Gilson and Hinton having proceeded in advance on February 18 to present their credentials to the Peruvian Government and to arrange for camp and commissariat on the lake, on which it is hoped to obtain six months' continuous observation. Besides the necessary scientific equipment, the expedition is taking out a motor-launch especially equipped for its daily observations, its speed of 16 knots at sea-level reduced to about 10 knots at this altitude. While the whole of the members of the expedition in respect to its objects are to a large degree interchangeable, it is anticipated that they will fall into pairs concerned with the chemical, physical and shallow water ecological observations, the plankton, fauna and flora being the concern of all. Clearly, this expedition will not be a 'joy-ride', and it is one to which the good wishes of all the scientific world will be gladly extended.

The Measurement of Time

By Prof. H. Dingle

TIME cannot be measured as any other physical magnitude is measured. Measurement is the determination of the number of 'units' contained in the assigned quantity, and the unit is defined either (as with mass and space) as an arbitrarily chosen, permanently preserved piece of the magnitude in question, or (as with temperature, electric charge, etc.) as that which produces a specified amount of an arbitrarily chosen effect ultimately measurable in terms of mass or space. But it is impossible to preserve a standard second, and time produces no effects—events occur *in* it but not *because of* it. Consequently measurement of time must be a special process.

The only practicable procedure so far conceived is the following. Choose a sequence of events (natural or artificial) between consecutive members of which there is an interval of some other (measurable) physical magnitude as well as an interval of time; then the time intervals can be defined as proportional to the corresponding intervals of that magnitude. This process involves three successive steps:

(1) Choice of the kind of measurable interval between the events.

(2) Choice of the particular sequence of events separated by intervals of this kind.

(3) Choice of the unit of measurement of those intervals.

Physics has chosen under (1) intervals of space; under (2) the successive spatial positions of an ideal body free from external forces—represented approximately by the successive directions of a specified radius of the earth; and under (3) an ideal rigid rod, represented approximately by the standard metre.

Each of these choices is in the last resort arbitrary; there is nothing in Nature to prohibit the selection, for example, under (1) of intervals of mass, under (2) of the successive masses of any particular body, and under (3) of any standard unit of mass. There are differences in convenience, of course: no sane physicist would normally define equal times as those in which a Californian redwood tree acquired equal increments of mass according to a standard piece of uranium. But so far as Nature is concerned, this and the traditional measure adopted by physics are equally valid.

Before the theory of relativity was formulated, it was thought that each of the three steps was prescribed by Nature. Time must be measured in terms of a sequence of spatial intervals; there was one unique uniformity of velocity defining the only valid sequence of spatial positions; and there was one unique standard for measuring the spatial intervals between those positions. Then came the discoveries that two rods, equal in length when relatively at rest, became unequal when in relative motion, and that in the latter circumstances it could not be determined which was moving. It followed that Nature's standard measuring rod in (3) could not be identified. Relativity saved the situation by pointing out that it was mythical, all standards being equally legitimate if used consistently. This discovery of the arbitrary character of step (3) is known as *special relativity*.

Steps (1) and (2) remained unique. This meant, first, that the unit of time must share the voluntary character of the unit of space, for since, under (1), time intervals were proportional to space intervals, any arbitrariness in the latter must appear also in the former; and secondly, that whatever choice was made under (3), the changes in space and time measurements could never convert uniform into accelerated motion, or vice versa, because, to preserve the uniqueness of (2), the units must be related so that the earth rotated uniformly. The supposed absoluteness of step (1) accounts for the common statement that time has become space. Having decided to measure time in terms of space measurement, it naturally follows that time and space measurements are related, but the relation does not belong to Nature. If intervals of mass or temperature had been chosen in (1), time would have 'become' mass or temperature. Again, the supposed uniqueness of step (2) accounts for the restriction of special relativity to uniform velocities: the equations of transformation had been determined experimentally for such velocities and the passage to accelerations was closed.

The next advance was the realization of the essential arbitrariness of step (2). Nature makes no demand that the earth shall rotate uniformly; we can choose *any* sequence of spatial positions, measure the space intervals between them by *any* standard rod, and define equal times accordingly. This discovery was *general relativity*; it destroyed the supposed absolute distinction between uniform and accelerated motion.

The effect on formal physical theory was in each case a simplification: special relativity eliminated time, and general relativity mass (or force), as independent conceptions. A velocity was no longer definable only as so many space units divided by so many time units. A velocity of 4 miles an hour was a movement through 4 miles while the earth rotated through 15°, and could be expressed as "4 miles per 15°". Space (or space-time, as it was called) measurement was thus adequate to describe velocity. A further elaboration of space measurement included force or mass, so the whole of metrical mechanics became expressible in terms of a single concept of space.

The arbitrariness of step (1) is not yet generally realized, but clearly we are just as free to choose a sequence of, say, entropy intervals as one of space intervals to define a time scale, and as a result we might expect an expression of the laws of thermodynamics in terms of a timeless entropy just as the laws of mechanics are expressed in terms of a timeless space. Two opposite extreme attitudes of physicists to this matter require attention.

In the first place, though apparently no one has explicitly noted the arbitrariness of (1), it is inherent in Milne's recent kinematical theory. Milne points out that any sequence of events whatever is valid for enumerating time instants, and this clearly gives us permission to choose events separated by intervals of any kind to provide a measure system for time. But he goes no further: having claimed freedom he takes no advantage of it, so that his claim, though perfectly just, is also perfectly useless. Instead of proceeding to advance physics by measuring some physical interval between the events chosen and defining a time scale in terms thereof, he restricts his consideration to the numbers identifying the instants themselves. The result is naturally that nothing of physical interest emerges; it is impossible even to distinguish between relative rest and relative motion until some choice of clock is made. Milne tries to define a basis of choice by postulating a 'cosmological principle', but this, being obviously beyond experimental confirmation, is metaphysical, and furthermore has not succeeded in making the distinction mentioned. Time is essentially immeasurable by ordinary processes, and you get out of its so-called measurement just what you put in. If you measure time in terms of space, time becomes space; if you measure it in terms of temperature, time becomes temperature; and if you measure it in terms of a cosmological principle, time becomes metaphysics.

At the other extreme is the position taken by the majority of physicists who, ignoring the voluntary character of (1), by implication accept as a natural necessity the measurement of time in terms of space. Probably the most emphatic expression of this acceptance is Eddington's statement ("The Nature of the Physical World", p. 74) that the second law of thermodynamics holds "the supreme position among the laws of nature". His reason is that this law alone reveals "time's arrow". But clearly this distinction is arbitrary. Having elected in (1) to measure time spatially, we can choose, and have chosen, in (2) for defining equal time intervals the particular sequence of spatial events that puts an arrowless time in mechanical laws. Thermal laws, being temporally 'out of step' with mechanical laws, then show time's arrow. But if we choose in (1) to measure time thermally, and in (2) the sequence of thermal events which puts an arrowless time in the laws of heat (for example, we might define as equal times those in which a standard body radiates equal amounts of heat or falls through equal ranges of temperature or changes by equal increments of entropy, etc.—heat, temperature and entropy measurement, of course, being defined by an arbitrary choice under (3)), time's arrow goes over into mechanics, which then assumes the 'supremacy' now assigned to thermodynamics.

We must distinguish two things:

(*a*) The *order* of events in time.

(*b*) The *intervals between* events in time.

The first is independent of measurement and is not arbitrary. The second, which alone give us our mathematical 'laws of Nature', depend on measurement which is arbitrary in the three-fold manner indicated above. For example, the statement that entropy tends to increase belongs to (*a*); the statement that the increase tends towards a finite maximum value depends on (*b*). If we define equal times as those during which a standard body acquires equal increments of entropy, there is no finite maximum value, and the entropy of that body increases uniformly through eternity.

The system of measurement to be chosen depends on the question of interest. If we ask whether terrestrial life will ever cease through failure of solar heat supply, the appropriate system must be indicated by the biologist; if rhythmic vital processes adapt themselves to solar heat supply such cessation will never occur, but if they adapt themselves to our physical system of (approximately) uniform rotation of the earth, it probably will. The former would seem more likely to be the fact. There is, however, the further consideration that life may depend on terrestrial (determined by solar) temperature more than on heat supply (though the present maintenance of the same body temperature in the arctic and tropic zones prohibits dogmatism on this point), and the fact that the sun cools comes under (*a*) and not (*b*). That is true, but there is no evidence that it is a 'fact'.

Apart from arbitrary choice, there seems to be complete equivalence between mechanical and thermal processes. Both show a one-way tendency in (*a*)—moving bodies tend to stop and hot bodies tend to cool. We do not need a special entropy clock to show which of two instants is the later; a grandfather clock will do—the later instant corresponds to the lower position of the weight. In favourable circumstances (for example, the rotation of the earth), 'uniform' motion may be eternal, and in favourable circumstances (for example, the radiation of the sun) 'uniform' radiation may be eternal. There is no evidence that the sun's temperature is falling, apart from the laws of mechanics, which presuppose fall and are therefore inapplicable: on the contrary, there is much difficulty in accounting for the fact that the sun radiates *without* observable fall of temperature. We are no more compelled to say that an isolated body would move uniformly than that it would radiate uniformly: in each case we can observe only bodies that are not isolated, and we find, first, that neither motion nor radiation is uniform, and secondly, that the nearer we approach isolation the nearer we approach a *common* uniformity of both motion and radiation.

Space prevents discussion of the possibility of re-expressing thermodynamics in terms of a thermal time measure, but there seems to be a reasonable prospect that choice of the proper thermal quantity for the purpose, and application of relativity methods of relating time with this quantity, would introduce the quantum of action, h, in a manner analogous to the introduction of the velocity of light, c, into spatial relativity. The relation of one constant to thermal processes at least partly resembles that of the other to mechanical processes. If this possibility were realized, the way would be open for a completely unified field theory. This, of course, is at present a speculation, but the three-fold arbitrariness of time measurement and the deductions drawn therefrom rest on logic and historical fact.

Obituary Notices

Prof. Max C. W. Weber, For. Mem. R.S.

DR. MAX WEBER, for many years professor of zoology in Amsterdam, doyen of late of the whole brotherhood of zoologists, died at Eerbeek on February 7, in his eighty-fifth year. He was born at Bonn on December 6, 1852, of a Dutch mother and a German father, and learned his natural history from Franz Leydig in Bonn and from Eduard von Martens in Berlin. Leydig was an excellent anatomist, who gave Weber his lifelong bent towards mammalian anatomy; von Martens, a famous conchologist, who had travelled and collected in the East, was a man of fine taste and liberal education. In 1879, Weber went to Holland, where he taught anatomy, first in Amsterdam then in Utrecht, and presently went back to Amsterdam as professor of zoology. In 1883 he took out papers of naturalization, and married Mlle. Anna van Bosse, a young botanist of his own age, who proved herself the perfect wife and helpmeet.

Weber had already made a voyage to Barents Sea, in a little schooner 75 ft. long, the *Willem Barents*, named after Willem Barents who had discovered Spitsbergen at the end of the sixteenth century and so opened the way to that rich whale-fishery in which the Dutch had a paramount share for the next hundred years. The *Challenger* had not long come home, and Weber, like many another young naturalist, was all agog to go fishing in unexplored seas with dredge and trawl. For a few years after their marriage the Webers went every summer to Tromso, he mostly to dissect whales, and she to study corallines or calcareous algæ, on which she was even then becoming the chief authority. In 1888 they went to the Dutch East Indies, where they made large and varied collections and where Max Weber took up in earnest the study of geographical distribution. He belonged to an age, and he was of late its most conspicuous survivor, when a man could take all natural history for his province, and could make discoveries in many diverse fields. In the *Ergebnisse* of this Dutch East Indian Expedition, in which many colleagues including his old master von Martens came to help him, Max Weber himself wrote on the freshwater sponges, on that queer trematode worm *Temnocephalus*, which is a parasite (and yet scarcely a parasite) on a river-crab, on the anatomy of certain Siluroid fishes, on local species of reptiles and of mammals, on the scaly coat of the pangolin and its associated hairs—which led him to think that all mammals were once scaly, and that in many the arrangement of the hairs recalled the ancestral pattern of the scales—and lastly, together with his wife, on the green and yellow algæ symbiotic (to use a word lately coined by De Bary) in *Spongilla*.

The Webers' next journey was to South Africa—it was always to some homeland of the Dutch—again to study the freshwater fauna, and in Max Weber's case to study the anatomy of *Chrysochloris* and certain other South African mammals: the results of this expedition were published in the *Zoologische Jahrbücher*. Then, in 1899, Weber, resigning his professorship and becoming professor extraordinarius, embarked (of course with his wife) on their famous Siboga expedition to the Dutch East Indies. The *Siboga* was twice as big as the *Willem Barents*, but was still a very little ship; she was of some 800 tons burthen, and carried a crew of fifteen all told. But the scientific work she did and the collections she brought home were out of all proportion to her size and the modest cost of the expedition. The splendid series of Siboga reports have been coming out under Max Weber's editorship for all these years, and are scarcely finished yet: they carry on the work that Rumphius had begun two hundred years before and that had been in abeyance ever since; and they give the *Siboga* an honourable place among the reports of the great historic voyages of exploration.

The Dutch East Indies are classic ground for the study of geographical distribution, and Max Weber had it from the first in mind to re-study Wallace's line, or whatever better boundary there might turn out to be between the Indian and the Australian regions. He was soon out of conceit with Wallace's line, which runs in the channel, not a deep one, between Bali and Lombok—"diese unglückliche Linie von Wallace", as he called it; rather does the Indian fauna begin to be impoverished in Bali, and to dwindle out in Lombok and Timor. Celebes is the great puzzle, not only as to the boundary-question but also for other questions of its own. It is an old story, but a truly amazing one, that the rich freshwater fish fauna of Sumatra, Borneo and Java, each of them with a hundred and fifty species less or more, practically disappears in Flores and Timor and Celebes: there is nothing left but one or two immigrants from the sea like *Symbranchus*, and one or two widespread fishes, tenacious of life, like *Anabas* and *Ophiocephalus*. Great families, Silurids, Cyprinids, Mastacembalids, simply disappear as we pass from Borneo to Celebes. As to what is often called the mixed fauna of Celebes, Max Weber was, I think, the first to lay stress on the great difference between the north and south halves of the island. Each half has its own population of squirrels; *Babirusa* and *Paradoxurus* and certain monkeys are confined to the north; and of sixty-four species of land-snails, only two are common to the two halves of the island. It was Max Weber who pointed out that, while Celebes occupies a deep-water area and Borneo, Java and Sumatra a shallow-water or continental one, the deep water around Celebes has a temperature of above 3°, instead of the usual 1° of oceanic bottom-temperature; there must therefore be some unknown barrier to separate the deep waters of the archipelago from the main ocean.

Conspicuous among the many Siboga reports are Max Weber's own on the fishes, marine and freshwater, and his wife's on the coralline algæ, or so-called nullipores. Mme. Weber van Bosse found these latter in vast abundance, though of few species; Stanley Gardiner had already shown their important share in the building of coral-reefs, and geologists knew their vast importance as rock-builders, even (or so we are now told) in pre-Cambrian antiquity! As to the fishes, Bleeker, who had studied them for twenty years, had made known many hundreds of species from the rich tropical East Indian fauna; but among a thousand species in all, Max Weber found a hundred and thirty-one that were new to science, and two hundred and forty more that were new to the area in question. In Bleeker's time the deep-sea fishes were all unknown, there and elsewhere, for the *Challenger* and the *Valdivia* had not begun to discover them. Max Weber dedicated his great work on the Siboga fishes to his wife—"die mir im hohen Norden, in Süd-Afrika, im indo-australischen Archipelago, und auch während der Siboga Expedition eine immer freudige und hülfreiche Reisegefährtin war". In his later years, with the help of his pupil and successor Prof. L. de Beaufort, Max Weber undertook the task of setting in order the whole Indo-Australian fish-fauna, of some three thousand species in all. Of this great and laborious work seven volumes have appeared, and the old scholar was busy with the proof-sheets until within a few weeks of the end.

In the midst of all these great undertakings Max Weber had found time to write what is in some ways the greatest of them all, his text-book of the Mammalia. We have seen how comparative anatomy was his first love; he worked for years in Amsterdam in an old and rich museum, and next door to a fine zoological garden, which gave him continual work to do. His book "Die Säugetiere", did for mammalian anatomy what Owen had done when Weber was a boy; it was first published in 1904, and a much enlarged edition appeared in 1927–28, to which Otto Abel contributed the palæontological part and Prof. de Berlet (now of Groningen) certain anatomical chapters. From the days when he first learned his anatomy from Leydig, Max Weber never ceased to work at that inexhaustible and delightful theme; and among all his other abundant work, "Die Saugetiere" stands out a monument to his industry and his learning.

Max Weber was a childless man, but he had all else that should accompany old age. He was rich in honours. He had the order of Orange Nassau, the knightly order of the Lion of the Netherlands, and several foreign decorations. He was a foreign member of many academies, including our own Royal Society.

Weber was a great figure of a man. He had both charm and dignity, and he enjoyed for many years such general admiration and esteem as are only given to the very best of men. Fifteen years ago, when he reached his seventieth birthday, a letter was sent him by a number of English zoologists. They spoke with unaccustomed warmth, saying in conclusion: "Your solid learning has upheld the great scientific traditions of your country, your investigations have influenced and stimulated many of us, your broad interests, your singleness of purpose, the simplicity of your life and your genius for friendship have set an example for us all" (NATURE, **110**, 780, Dec. 9, 1922).

D'ARCY W. THOMPSON.

Dr. R. F. Rand

RICHARD FRANK RAND, a brilliant young surgeon trained at Edinburgh, was one of the Rhodesian pioneers and served as medical officer with the pioneer column sent by Cecil Rhodes to Mashonaland in 1890. As medical officer to the Chartered Company's police, and later chief hospital surgeon at Fort Salisbury, he devoted himself specially to the treatment of malaria, the scourge of the early settlers and then not recognized as a mosquito-borne disease.

The active period of Dr. Rand's long life was spent in practice in South Africa, chiefly at Salisbury and other places in Southern Rhodesia, and his great experience of tropical diseases was an important asset to the British forces in the Boer War and later in the Great War. His last years were spent in England, and he died very suddenly at his home at Brightlingsea, Essex, in his eighty-first year on January 3.

Rand was a keen naturalist, his great hobby was live botany; he not only collected but also keenly studied his plants in the field in intervals snatched from his always exacting medical duties. His collections of specimens sent to the British Museum Herbarium were accompanied by notes of his observations on their relation to environment, life-history and especially on details of floral structure and dispersal. He was one of the earliest collectors in Southern Rhodesia, and his gifts to the Museum in the late 'nineties and the early years of the present century provided many novelties. Accounts of these and his valuable field-notes and observations were published in the *Journal of Botany*. A. B. RENDLE.

Prof. David Ellis

PROF. DAVID ELLIS, professor of bacteriology in the Royal Technical College, Glasgow, died suddenly at his home in Bearsden on January 16, aged sixty-two years. He was educated at the University College of Wales, Aberystwyth, and after graduating in the University of London in 1896, taught for some time as a science master in secondary schools. Later he proceeded to the University of Marburg where he gained his Ph.D. degree in 1902, for researches in bacteriology. On returning to Great Britain he again took up science teaching, this time in Dollar Academy, and from there he went, as lecturer in bacteriology and botany, to the Glasgow and West of Scotland Technical College, the lineal descendant of the old Anderson College, now the Royal Technical College, Glasgow. Later he was appointed professor of bacteriology in the College and superintendent of its Schools of Pharmacy and of Bakery.

For his researches in mycology, Ellis obtained the D.Sc. of London in 1905. From 1907 until 1919 he was lecturer in nature study to the Glasgow Provincial Committee for the training of teachers, and during that period he was, for many years, chief examiner in botany to the Central Welsh Board. He was an early and successful worker in the field of adult education, his popular lectures in botany attracting many hundreds of people of the type which has the desire for learning but little opportunity of acquiring a scientific training. His work covered a wide field; and in the performance of the duties associated with the Schools of Pharmacy and of Bakery he showed a marked gift for the expression of scientific subjects in simple language.

Prof. Ellis was widely known for his work on the iron bacteria and the sulphur bacteria, on each of which subjects he had published a monograph. In addition to his more recondite publications he contributed articles to the press on scientific topics and was the author of "Outlines of Bacteriology", "Guide to the Common Wild Flowers in the West of Scotland" and "Medicinal Herbs and Poisonous Plants".

Prof. Ellis's services were in demand as an expert on problems relating to the disposal of sewage, and frequently he figured as a consultant in law cases, when water pollution had led to litigation in which the interests of communities were involved. Such was his authority on this and kindred topics that he was consulted by Government departments including the Department of Health. His leisure time was divided between golf and the care of his garden, and it was while happily employed in his garden that he died. He is survived by two sons. J. P. T.

Dr. W. V. Shaw, O.B.E.

DR. WILLIAM VERNON SHAW, a member of the medical staff of the Ministry of Health, died on January 21, aged sixty-three years.

Dr. Shaw had a brilliant career at Oxford, where he gained first-class honours in the final honour school of Natural Science, and at St. Mary's Hospital. He had a distinguished career in the public medical service first as medical officer of health for the Malton and Norton rural district, and later at the Ministry of Health. He was an expert epidemiologist and did valuable work for the Ministry in the investigation of outbreaks of infectious disease in many parts of the country. His diagnostic skill particularly of smallpox was widely recognized.

WE regret to announce the following deaths:

Prof. William Campbell, Howe professor of metallurgy in Columbia University, and an authority on physical metallurgy, on December 16, aged sixty years.

Dr. W. H. Collins, consultant to the Branch of Mines and Geology of the Canadian Department of Mines and Resources, and acting director of the National Museum, formerly director of the Canadian Geological Survey, on January 14, aged fifty-eight years.

Prof. Louis Mangin, director of the Marine Laboratory of the National Museum of Natural History, St. Servan, formerly professor of cryptogamic botany in the National Museum of Natural History, Paris, aged eighty-five years.

Prof. Bindo De Vecchi, since 1930 Rector Magnificus, and since 1925 professor of pathological anatomy of the University of Florence, on December 28, aged fifty-nine years.

Prof. R. L. Weighton, emeritus professor of engineering in Armstrong College, Newcastle-upon-Tyne, on February 19, aged eighty-five years.

News and Views

Sir James Frazer, O.M., F.R.S.

AT a dinner and reception given by Mme. M. Levinskaya at 2 Leinster Gardens, W.1., on February 17 in honour of Sir James Frazer and to celebrate his attaining the age of eighty-three years on January 1 last, Prof. B. Malinowski spoke in appreciation of his contribution to the study of man. After referring to the pre-eminent position long held by Sir James among anthropologists, he said that while such pioneers in the study of the early forms of religion as Mannhardt, Tylor and others looked to animism and the belief in spirits, Sir James was the first to indicate the place and junction of magic in primitive belief and to demonstrate the significance of magical practice and ritual in man's early conceptions of the universe. Further, that what Andrew Lang some twenty-five or thirty years ago flippantly termed "the Covent Garden school of anthropology", had become the fundamental principle in a great body of anthropological investigation into such beliefs as that of the spirit of fertility, the mother goddess and the like; while what was intended to be no more than a short essay of twelve pages dealing with the Priest of Nemi had grown into the twelve volumes of "The Golden Bough". Of all Frazer's great qualities, the most marked, as well as the most immediately striking, was his transparent and single-minded devotion to the cause of truth. He had never been so wedded to his own theories as to seek to impose them upon others in such a manner as to obstruct the attainment of the truth. He had never hesitated to abandon a theory which conflicted with further examination of the facts or fresh evidence, as was shown by the development of his views on totemism. In conclusion, Prof. Malinowski pointed out that, in principle, the studies upon which Sir James had been engaged were not confined to primitive man alone; they were equally applicable to our modern civilization—an application especially needed in the conditions of the world to-day.

Native Policy in Northern Rhodesia

SOME important observations on policy, present and future, in the administration of native affairs in Northern Rhodesia were made by the Governor of that Dependency, Sir Hubert Young, when addressing the members of the East African group of the Over-Seas League at Over-Seas House on February 19. It was evident from his remarks that, while the cosmopolitan population of the mining area naturally is concerned primarily with the interests of copper, the most important industry in the country, the outlook on the native question is somewhat different in other districts. In a country in which there are one and three quarter million natives to eleven thousand Europeans, it is recognized, Sir Hubert said, that the native has a right to have work most suited to him. Presumably it would be legitimate to interpret this as meaning, in less diplomatic terms, that the development of the native along lines in harmony with his own culture is to be the aim of administration, rather than the exploitation of labour solely to meet the needs of a European industry, important though this may be. An announcement, welcome in this connexion, was that an anthropological institute is to be established. This will ensure—or at least, so it may be hoped—that native custom and cultural trends will be studied thoroughly in order to meet the needs of administration. It will certainly afford an indispensable aid in the attempt which is now being made to re-establish the native organization and the native authorities. Sir Hubert Young expressed himself as "rather a heretic" in the matter of indirect rule. In view of the difficulties of re-establishing a system which now for some years has been in process of disintegration, it will perhaps be wise not to expect too much. At the same time, in regarding it as a training only, Sir Hubert wisely emphasized a fact often overlooked, that indirect rule cannot be an end in itself.

Archæological Investigations in Western Asia

SIR LEONARD WOOLLEY, accompanied by members of his archæological expedition, left England on February 23 for Syria, where excavations will be resumed on sites in the Antioch region early in March. The personnel of the expedition includes Lady Woolley, Mr. E. A. Lane of the Victoria and Albert Museum, who was with Sir Leonard at Ur, and Mr. Murray Threipland, who was a member of the expedition last year. Work will be resumed on both the coast and the inland sites. Results from the latter will be awaited with special interest, in view of the significance of the evidence obtained last year from a preliminary examination of the site of Tell Atchana on the River Orontes, which, as Sir Arthur Evans has pointed out, when viewed in conjunction with the evidence from the other Syrian site of Ras Shamra and that from Palestine, for the first time carries the relation between this region of western Asia and Minoan Crete back so far as 1700 B.C. Further indications are not wanting that the diversion by circumstance of the preoccupations of archæologists from the Mesopotamian area to peripheral regions, which to many at first sight seemed deplorable, will have speedy and far-reaching beneficial effects. Especially worthy of note in this connexion are the recent discoveries of the Neilson Expedition of the University of Liverpool on Cilician sites at Serkeli (*The Times*, Feb. 13) and of Miss Winifred Lamb, whose report on recent developments in the prehistory of Anatolia was presented before the Society of Antiquaries on February 19.

MISS LAMB, before dealing with her own excavations on the newly discovered site at Kusura, which began in 1935, pointed out that recent archæological investigations in Anatolia had deduced from the surface examination of prehistoric mounds and the excavation of two or three large sites, that during the Bronze Age two main cultures were to be distinguished, of which one, a western, had affinities with Troy, and the second, a central and eastern culture, was marked by the principal Hittite remains. Kusura lies on the southernmost of three routes from east to west of which one extends to Troy, the second to the coast near Smyrna, while the third, with which she was concerned, traverses the upland plains south of Afyonkarahissar. The town itself, it would appear, was occupied for the first time about the end of the fourth millennium B.C. A cemetery yielded pottery markedly local in character, unlike anything found elsewhere in Asia Minor. This strongly marked local character in the culture Miss Lamb found to persist even at the end of the Bronze Age, when there were signs of Hittite influence as well as of connexions with Troy. Further evidence relating to the 'indigenous' culture and its contacts with east and west will obviously be of considerable interest, especially in view of the results obtained by the Neilson Expedition at Serkeh, where also, judging from the preliminary report, there appears to be a strongly marked local culture. This is clearly of considerable antiquity, as it underlies levels which correspond with the earliest culture of El Obeid and Arpachiyeh in Mesopotamia. The stratum in question is said to be nine feet thick and to lie at a level of twenty-five feet below the Hittite levels. Its distinguishing feature is a peculiar painted pottery and plain pottery, while obsidian and flint were in use.

Promotion of International Equity

A PRELIMINARY outline of the proposals of the New Commonwealth Society for the creation of an equity tribunal for the settlement of non-justifiable disputes between nations is contained in a pamphlet, "An International Equity Tribunal", which has just been issued by the Society. It is urged that three institutions are required: (1) a body endowed with the legislative function and with the power to effect peaceful changes in the public law; (2) a court to interpret that law; and (3) a police force to uphold the decisions of the Court and to maintain law and order. The League of Nations is considered the foundation upon which the structure of an enduring peace is to be built, and these institutions should form part of its permanent machinery. By an equity tribunal is meant an impartial or neutral body which is called upon to investigate a political or industrial dispute, and the findings or awards of which are based upon natural justice. Consequently an international equity tribunal would be capable of effecting peaceful change in the public law, including the revision of treaties, and would be empowered to arbitrate upon all political disputes which cannot be settled by negotiation and conciliation. The members of the equity tribunal would require to sever their connexion with the Governments and politics of their respective countries and devote their time exclusively to the service of the tribunal and of the League. An embryonic example of the working of an equity tribunal may be seen in the Lytton Commission, and a further stage towards the development of the tribunal system would be the creation of permanent committees by the Council or the Assembly in place of such *ad hoc* bodies.

IT is suggested that the formation of an equity tribunal with a permanent and independent status, with members elected in the same way as the judges of the Permanent Court, is likely to provide the most effective machinery for the adjudication of political disputes and the revision of treaties. Its addition to the machinery of the League would disarm the assertion of certain non-members that the League is simply a vehicle for protecting and sponsoring special interests. The tribunal would be related to the Permanent Court, possibly as an independent division, with a personnel not consisting mainly of lawyers, and enforcement of its awards in the last resort would be secured by the existence of an international police force. The pamphlet is obtainable from the New Commonwealth Society, which has established itself as one of the most active organizations working in the field of international peace. Particulars of its work and conditions of membership can be obtained from the Secretary, Thorney House, Smith Square, Westminster, S.W.1.

Organization in Petroleum Research

RESEARCH is necessary in practically every phase of the petroleum industry to-day and, in view of its importance, should be prosecuted in the most efficient and economic manner possible. In a paper read before the Institution of Petroleum Technologists on December 8, J. H. Vermuelen discussed the organization of research. The main point to which he directed attention was that although decentralization is inevitable in every petroleum company owing to its very nature, yet its technical and administrative activities should be controlled and guided by a central laboratory. The laboratory should be so designed and equipped that routine and ordinary research can be carried out at the same time as applied and pure research and, while there should be no interference between the two types of research, yet there should be ample facilities for exchange of ideas. The routine function of the central laboratory should be to collect technical and commercial data from all branches of the company, systematize it and render it available in a convenient form for reference.

AT the same meeting of the Institution, W. C. Asbury and D. A. Shepard threw further light on the organization of research by a description of methods adopted by the Standard Oil Co. (N.J.). Since its inception, sixty-five years ago, the company has been engaged continuously in research, and has had to meet the diversified interests and needs of several hundred subsidiary companies. Its technical organization has grown on lines which combine centralization and decentralization. Problems peculiar to one operating unit are studied in laboratories controlled by that unit, but in addition all operating units are served by a commonly controlled central staff organization which incorporates research and development laboratories and co-ordinates the technical, scientific and patent activities of all units. Further, it has long been the practice of the company to support research programmes in special fields in university laboratories and to give recognition to the contributions to petroleum technology made by scientific workers and technologists. This is perhaps the most striking manifestation of the necessity felt by petroleum companies for some form of decentralization and external collaboration.

Calf of Man as Nature Reserve

MR. F. J. DICKENS of Silverdale, Carnforth, Lancashire, is presenting the Calf of Man to the National Trust. This gift should prove a very valuable addition to the island bird sanctuaries of the British Isles. The Calf, with the rocks to the south of it and Chicken Rock Light, have provided invaluable facilities for bird migration study, and as it is proposed to have the property managed by a committee of ornithologists and Manxmen, there is a unique opportunity for erecting another ringing station or bird observatory of the Isle of Man and Heligoland type there. Covering some 616¾ acres, more than four hundred of which are healthy pasture, and including steep cliffs, a marsh, farm, ponds, a dam, and a glen, the Calf of Man as a bird reserve would preserve the nesting sites of some thirty species of bird including such birds as the chough which, declining in Cornwall and Devon, is increasing in the Isle of Man, the peregrine falcon, the shag, puffin, guillemot, razorbill, raven, kittiwake, rock-pipit, etc. There is a farm where a few house-sparrows, starlings, and blackbirds find a living, and wrens inhabit the caves. On migration, many warblers visit the Glen, etc., and forty-eight species of birds have been noted at the Chicken Rock Lighthouse (so named by sailors from the abundance of the storm-petrel or Mother Carey's chicken off that low rock). There may no doubt be need for some scientific control of the bird numbers, as in recent years the greater black-backed, lesser black-backed and herring gulls have increased their nesting areas, and these rapacious birds are often a danger to more interesting, but less vigorous, species. The flora has not been worked so thoroughly, but some three hundred or more plants occur, including the yellow-petalled 'ochrocyanea' variety of wild radish near the farm, wild hyacinth in a curious marshland habitat near the landing Sound, and sundew.

Bird Migration and Air Currents

AT the annual conference of the International Faculty of Sciences, held in London on January 29–30, Capt. B. Acworth presented a paper entitled "New Light on Bird Migration". But the paper contains nothing of importance that was not set down lucidly and with similar diagrams in his "This Bondage" in 1929. There is the same useful insistence upon the effects of wind currents upon the movements of birds, and alas, the same errors are repeated. For example, Capt. Acworth insists that the permanent winds of the tropics form impassable barriers; that consequently "the species of birds found in particular temperate zones must have had *separate origins*"; and that these facts "seem to demolish . . . the theory of evolution as it affects the common origin of birds." But surely the fact that every autumn and spring in the Old World and the New birds do actually cross, as a matter of routine, the "impassible barrier" of the equatorial currents demolishes the whole argument. Again, the exact knowledge of the writer of the Book of Exodus in describing how "the east wind brought the locusts" is contrasted with the ignorance of biologists, anatomists and embryologists; but records of insect migrations show that the wind is not the directive factor in a large percentage of cases. Lastly, "*seasonal* winds have always ensured the translation of birds to parts of the world agreeable to the essential needs of the appropriate species", which, if it means anything at all, means that wind and no biological factor has settled the agreement between birds and their environment.

Agriculture in Tanganyika

THE annual report of the Department of Agriculture in Tanganyika for 1935 has now been published (Dar-es-Salaam: Government Printer, 1936). From the economic point of view, the past five years have been the most critical in the history of the Territory, and 1935 can be regarded as the culminating point of the effort to place it in a position of economic security. The volume of total exports attained has never before been approached, in spite of the fact that record figures for most crops had been reported during the four previous years. In the year under review, records for the export of the three premier industries, sisal, cotton and coffee, have been achieved, while high figures are again reported for ground-nuts, bees-wax and sesame. Copra alone has yielded disappointing results. The soundness of the policy of increasing production in a territory which has not reached the limits of development seems to have been vindicated, as the standard of living and purchasing capacity of the native peoples have been markedly improved, and also a rise in the value of exportable commodities obtained. As regards non-native agriculture, the excellent price secured for sisal-hemp stimulated the rejuvenation of estates, re-equipment of factories and a general re-organization of the industry. Much too large a proportion of planters, however, still rely on a one-crop policy, and the adoption of a more diversified farming is advocated. Native development is making sound progress, successful concentration of population now being possible in districts which quite recently were poverty-stricken tsetse areas. Questions of irrigation and natural water supplies play a vital part in African life, and important developments are already in hand following the recommendations of the special inquiries completed during the year under review.

Progress in Grass Drying

AT the second Congress of Mechanised Farming held at Rhodes House, Oxford, on January 5–8, when recent developments were described, a paper by Mr. E. J. Roberts on "A Year's Progress in Grass Drying" excited much interest. A résumé of this paper is published in *Engineering* of February 5. The author points out that whereas there were only six driers in operation in 1935, there were 46 by the end of the 1936 season. The engineering difficulties in connexion with drying plant have been successfully overcome. This is confirmed by papers at the Congress giving the experience of users. We know that inventors are busy developing new methods and rapid progress in this direction will doubtless soon be made. For the year just closed it is expected that the production will be 10,000 tons. In the United States for the same period, it was 50,000 tons. In countries abroad the usual practice is to dry the grass in large centralized units. In Great Britain, in general, only small localized units are used. This is a pity as it is not the most economical method. In a paper read at the conference by Prof. J. A. Scott Watson, it was shown that the remaining problems are to bring down the cost of the drying plant, the fuel cost and the labour cost and to increase the output. Mr. Roberts in his paper stated that one large drier evaporated 9 cwt. of water with 1 cwt. of coal for a short period and worked at a normal figure of 8 cwt. Smaller driers give efficiencies of 3¼–5½ cwt. of water per cwt. of coke. If we take the calorific value of the coal to be 14,000 B.Th.U. and that of the coke to be 13,000 B.Th.U., the advantage lies greatly in favour of the large drier.

Testing Broadcasting Receivers

AT an informal meeting of the Wireless Section of the Institution of Electrical Engineers held in November 1935, Dr. R. L. Smith-Rose opened a discussion on the methods of examining the performance of wireless sets used for the reception of broadcasting. No specification was then available of the standards of performance at which it was desirable to aim in the production of such receivers. Quite recently, however, the Radio Manufacturers Association has published a "Specification for Testing and Expressing Overall Performance of Radio Receivers", and a discussion on this specification was opened by Mr. Stuart Hill at a meeting of the Wireless Section of the Institution of Electrical Engineers held on February 3. The above specification is in two parts, dealing respectively with electrical and acoustic tests. The first part describes laboratory methods of measuring the sensitivity and selectivity of a receiver, and also its susceptibility to noise and the performance of its automatic volume control. The second part describes the corresponding methods of measuring frequency response, acoustic sensitivity, hum and acoustic output. In each case the proposed methods of expressing the results are described and illustrated by means of typical graphs included in the specification.

THE discussion at the Institution indicated that the initiative shown by the R.M.A. in producing this specification is very generally appreciated, although some criticism was offered on matters of technical detail. In so far, however, as Mr. Hill stated, the specification has been drawn up by manufacturers for manufacturers, its useful purpose is somewhat limited at the present time. Furthermore, it does not contain a suggested standard of performance, and this might very usefully be added after consultation with representatives of the users of such receivers and of the B.B.C. and other Government departments interested in the matter. In fact, the time would now seem to be opportune for such a body as the British Standards Institution to take up the subject by setting up a representative committee for the purpose of drafting a specification dealing not only with methods of testing, but also with the standards of performance to be attained by the various types of modern radio receiver. Such a standard specification has long been needed; it would be of great benefit to the radio industry as well as to the general public; and the labours of the drafting committee will now be considerably lightened by the pioneer work already accomplished by the Radio Manufacturers Association.

Standards of Radio Frequency

MODERN electrical measurements are conspicuous for the fact that the frequency of alternating currents can be measured to a very high order of accuracy. In order to provide a standard of frequency for scientific and technical workers, the National Physical Laboratory undertakes the emission of two types of frequency of reference from its own radio transmitting station. One of these is in the form of a modulation frequency of one kilocycle per second superimposed on a carrier wave of 396 kilocycles per second, while the other is a simple carrier wave of frequency 1,780 kilocycles per second. The programme incorporating the first frequency is emitted on the second Tuesday of each month at 10.40–12.00 G.M.T., while the second is emitted on the first Tuesday in March, June, September and December at 21.00–22.00 G.M.T. The modulation frequency employed in the first programme is derived from one or other of two oscillators, which are maintained in continuous operation at the National Physical Laboratory. One of the oscillators is an electrically maintained tuning fork vibrating at its natural frequency of 1 kilocycle per second; while the other is a quartz ring oscillator generating a frequency of 20 kilocycles per second, with the necessary attachment for selecting the required frequency of one twentieth of this value. In both cases, the accuracy with which the frequency is maintained is one or two parts in 10 million, but during each emission the exact frequency is measured at the Laboratory, and the correct value is announced at the end of the programme. For the second standard frequency emission, a separate quartz crystal oscillator is employed; in this case, no correction is announced, the frequency emitted being accurate to within one part in a million. A revised programme giving full details of these transmissions can be obtained on application to the Director, National Physical Laboratory, Teddington, Middlesex.

Lead Sheaths of Electric Cables

LEAD is a very suitable metal for providing a watertight covering to an electric cable buried in the earth. The weight of the lead sheaths made per annum in Britain alone is 64,000 tons. Taking into account the much larger quantity that must be used in the many cable factories throughout the world, it will be seen that an improvement in the technique of the manufacture of lead sheaths is one which seriously concerns both users and manufacturers. Of recent years, much thought has been given to this problem and very many patents have been taken out for improvements. In a paper by Dr. P. Dunsheath, read to the Institution of Electrical Engineers on December 3, a method for the continuous extrusion of lead sheaths over cables is described which is being widely adopted by manufacturers. Hitherto, the extrusion of the lead has been done by the ram of a hydraulic press. In Dr. Dunsheath's method, the pressure required to extrude the lead is obtained by means of a motor-driven screw member. In 1929 the first lead pipe was extruded by a continuous process, and the development has continued steadily up to the present. A defect of cable sheaths made on hydraulic presses is the inclusion in the finished pipe of welds between separate faces of metal, which at some stage in the process have been exposed to the air and therefore become slightly oxidized. Provided sufficient time is allowed to elapse and sufficient pressure applied at a sufficiently high temperature, two separate masses of lead will weld together completely into one homogeneous mass if the faces are clean and free from oxide.

Air Raid Precautions and Air Disarmament

A PAMPHLET entitled "Defence that is no Defence", by Dr. C. E. M. Joad, issued by the National Peace Council, directing attention to the inadequacy of the Government proposals for defence against air raids and the impossibility of devising any adequate protection against simultaneous attack by gas, explosive and incendiary bombs, quotes the warning against this barbarous perversion of science and industry in the tendency to accept the use of aircraft for unrestricted bomb and gas attack on civilized populations uttered by leading scientific workers when the Government schemes were first introduced. Subsequent events have only confirmed the prediction that acceptance of this position must rapidly lead to the breakdown of civilized life. Dr. Joad, while emphasizing the futility of the measures so far proposed by the Government and also the difficulty of its position, urges that the Government should work strenuously for abolition of the bombing aeroplane and for disarming in the air and placing civil aviation on an international basis, as affording the only security against destruction of our cities by attack from the air. He also urges a policy directed towards the removal of economic tensions which are endangering peace, and suggests a definite lead from Great Britain in regard to access to raw materials and equalizing of opportunities for trade which might be provided by an extension of the mandates system, the lowering of tariffs and removal of economic barriers.

Scientific Management and Economic Problems

IN an address to the Engineers' Study Group on Economics on January 19, Major L. R. Urwick spoke on the contribution of scientific management to the solution of present economic difficulties. He outlined the development of the principles of scientific management from the pioneer work of Charles Babbage and F. W. Taylor to such recent manifestations as "Stakhanovism" in Russia. Scientific management means essentially not the multiplication of efficiency experts but the adoption by both employers and employed of a new mental outlook, based on exact measurement and not on opinion, and more interested in increasing the output of industry than in haggling about its division. Resistance to Taylor's ideas had largely been due to those of his followers who had adopted his methods piecemeal while neglecting the underlying philosophy. Scientific management has spread much faster on the productive side of industry than on the distributive, or in finance, and the machinery of Government has also profited far less than it should have from the available knowledge of management problems. The first part of a chapter on "The Division of Labour and the Pricing System" has recently been forwarded in draft, and the chapter on "Money and Banking" has been discussed at a recent meeting of this Group.

Analytical Control of Foods and Drugs

Extracts from the annual report of the Ministry of Health and abstracts of reports of public analysts upon the analytical control of foods and drugs for 1935 have been issued as a separate pamphlet (Sale of Foods and Drugs. H.M. Stationery Office, 1936. 3*d*. net). No less than 143,831 samples were analysed by public analysts in England and Wales, of which 7,972, or 5·5 per cent, were reported against. The number of samples of milk examined was 78,674, of which 5,798 samples were reported to be adulterated or not up to standard. Several samples of canned products were found to be contaminated with tin, lead, copper or zinc. A few samples of sugar contained sand, and one of icing sugar rancid fat and dead flies. Adverse reports were made on a number of 'cream' cakes and pastries on the ground that the filling consisted wholly or partially of fat other than milk fat, and a number of 'chocolate' rolls and cakes contained no chocolate. The reports of the public analysts are abstracted in a series of tables.

National Institute for Research in Dairying, Reading

IN the annual report for 1935 of this Institute, which has recently been issued, the research and other activities are summarized. The research work includes such varied subjects as winter feeding of young dairy cattle and artificial insemination of cows, investigations on the chemical composition of typical milk and of taints of milk, the lactic acid bacteria and cheese-ripening studies, and on pasteurization and tubercle bacilli in milk. Cases of contagious abortion among the Institute's herd of cows gave an opportunity for investigating *Brucella abortus* infection. Bacteriological testing of milk samples and market milk investigations have also been carried out, and the phosphatase test for efficiency of pasteurization has been re-examined. The financial condition of the Institute is considered, and an appeal is made for further funds to enable an extension of the work to be made.

Oxford and Present Needs in Science

Referring to the leading article in Nature of February 20 under this title, a correspondent writes as follows: "As some readers may not be familiar with the names given to certain buildings in Oxford, it may be helpful to state that the 'Ashmolean Museum' now means the Museum of Art and Archæology, chiefly classical, established in Beaumont Street in 1890, whereas the 'Museum of the History of Science' means the ancient scientific collections in the Old Ashmolean Building, which was the only science museum from 1683 until 1860. In this building Ashmole's old museum room is now full to overflowing of historic instruments and specimens; and money is needed for its extension. The changes contemplated in the various scientific departments of the University make it more than ever necessary to provide for the preservation of things of historic value that might otherwise be scrapped".

Early Man in Minnesota

Prof. A. E. Jenks, of the University of Minnesota, reporting recently on "Minnesota man", a female skeleton found in ancient lake deposits in 1931, attributes to it an age of approximately 20,000 years, and regards it as the oldest specimen of early man to be found in America. The teeth had all erupted, with the exception of the wisdom teeth, but as the long bones appear to be still immature, the age of the girl was probably about fifteen years. The teeth are larger than normal in prehistoric man. In summing up the characters of the skeleton, Prof. Jenks, it is stated by Science Service, regards it as *Homo sapiens*, of an early type of evolving Mongoloid, forecasting the aboriginal American, especially the Eskimo, rather than the modern Mongol. It has been computed that the Lake Pelican deposits, in which the skeletal remains were found, antedate those of the glacial Lake Agasiz by some two thousand years, thus warranting this increase in the age usually admitted for early man on the American continent.

Sanitary Aviation in Soviet Russia

The sanitary aviation service maintained by the Red Cross and Red Crescent Society of the U.S.S.R. is fast becoming a regular institution for medical aid, particularly in outlying regions of the Union. Sanitary aeroplanes are kept in readiness in all parts of the Union to answer urgent calls for medical aid. In 1936, more than 400 patients were carried by air to hospitals and more than 500 specialists were taken by air to various places where they performed some fifty major operations and treated about four thousand seriously ill persons. In 1936 also, the sanitary aeroplanes of the Red Cross and Red Crescent Society carried more than 2,000 kilograms of medical supplies to different points of the Union.

Biochemistry in the U.S.S.R.

We have received the first five numbers of the first volume of a new Russian journal, devoted to biochemistry. It is entitled *Biochimia*, and is edited by A. N. Bach and W. A. Engelhardt. The papers are in Russian, but each is provided with a summary in English or German. The average size of each number is about 120 pages. The papers deal with work on vitamins, enzymes and other biochemical problems. The journal should enable workers in other countries to gain some idea of the work which is being carried out in Russia in biochemistry.

Comets

A new comet was discovered by Dr. F. L. Whipple at Harvard on February 7. Its magnitude was 12 at the time of discovery, and it was described as diffuse with a central condensation, and a tail less than 1° in length. Dr. Whipple computed the following parabolic orbit:

$$\begin{array}{lll} T & 1937\ \text{Jan}\ 22{\cdot}070\ \text{U.T.} & \\ \omega & \left.\begin{array}{rr} 111^\circ & 27' \\ 127 & 4 \\ 41 & 4 \end{array}\right\} & 1937{\cdot}0 \\ \Omega & & \\ i & & \\ q & 1{\cdot}6610 & \end{array}$$

It is now about 1·5 units from the earth, which it is approaching, but it is not likely to become a conspicuous object. Mr. Simizi in Japan detected Daniel's Comet, 1909 iv, 1937 *a*, on January 31. Its magnitude was 13 and it was diffuse without any central condensation. Mr. Hirose computed an orbit the elements of which are given below. It is receding from the earth, and is now more than 1·4 units distant.

$$\begin{array}{l} T\ 1937\ \text{Jan.}\ 27{\cdot}940\ \text{U.T.} \\ \left.\begin{array}{lrr} \omega & 6^\circ & 1' \\ \Omega & 70 & 19 \\ i & 19 & 50 \end{array}\right\}\ 1937{\cdot}0 \\ q\quad 1{\cdot}587 \\ \text{Period}\ 6{\cdot}825. \end{array}$$

The Night Sky in March

During March, the duration of night in the latitude of London decreases by nearly two hours. On March $21^{\rm d}\ 1^{\rm h}$ the sun enters the sign Aries (Spring Equinox). The moon is new on March $12^{\rm d}\ 19{\cdot}5^{\rm h}$ and full on March $26^{\rm d}\ 23{\cdot}2^{\rm h}$. No bright stars are occulted during the month, but the following disappearances may be noted: 108 Tauri (mag. 6·2) on March $18^{\rm d}\ 19^{\rm h}\ 39{\cdot}0^{\rm m}$ when the moon is 6 days old, and *e* Leonis (mag. 5·1) on March $25^{\rm d}\ 21^{\rm h}\ 54{\cdot}4^{\rm m}$, the moon being 13 days old. The planet Venus, which does not set until about $22^{\rm h}$, is a striking object and reaches its greatest brilliancy on March 12; the area of the illuminated crescent is then 0·28 that of the whole apparent disk. Mercury, being in superior conjunction with the sun on March 16, is not accessible to observation. Mars rises at about midnight and is about 1½° preceding the third magnitude star, β Scorpii. The planet brightens during the month from $+0{\cdot}4^m$ to $-0{\cdot}3^m$, its greatest brightness being reached in May. Jupiter, of stellar magnitude $-1{\cdot}6$ to $-1{\cdot}7$, will be found low down in the morning sky. Saturn, being in conjunction with the sun on March 16, is above the horizon almost wholly in daytime. On March 8, Neptune (mag. 7·7) in Leo is in opposition; the planet's distance from the earth will then be nearly 2,714 millions of miles. The zodiacal light may be looked for on clear evenings after sunset at the beginning and end of the month. On or about March 3 and March 30, the night sky may also be scanned for any appearance of the aurora; auroras were observed 27 and 54 days earlier in northern England and Scotland respectively, and this 27-day sequence may possibly be continued in March. In any event, auroral displays may now be looked for generally on account of the active state of the sun, and there is also a higher frequency of magnetic disturbances at about the equinoxes. The following positions at 0^h U.T. of Comet Whipple (1937 *b*) are given in Circular No. 636 of the *Bureau Central des Télégrammes Astronomiques*:

	R A.		Dec.	
	h	m	°	′
March 4	13	49·9	+45	42
„ 8		54·3	47	25
„ 12		58·3	49	6
„ 16	14	1·8	50	44

Announcements

The new ultra-centrifuge in the Department of Biochemistry of the University of Oxford will be inaugurated at 4 p.m. on February 27. The Vice-Chancellor of the University, the president of the Royal Society and Prof. The Svedberg, of the University of Uppsala, will be present.

At the annual general meeting of the Quekett Microscopical Club, held on February 9, the following officers were elected: *President*, W. E. Watson Baker; *Vice-Presidents*, E. A. Robins, J. T. Holder, Dr. C. Tierney, and Chetwynd Palmer; *Treasurer*, C. H. Bestow; *Secretary*, W. S. Warton; *Reporter*, A. Morley Jones; *Librarian*, W. E. Stone; *Curator*, C. J. Sidwell; *Editor*, W. P. Sollis. *New Members of Committee*: F. C. Grigg, N. I. Hendey, A. E. McClure, F. E. J. Ockenden, C. C. Swatman.

At a meeting of the president and fellows of Harvard College in Boston, held on January 18, it was voted "that the thanks of the President and Fellows be sent to Sir Robert Hadfield for his beautiful and welcome gift of a picture appropriately commemorating in this University the University of Oxford, with which during a period of three hundred years Harvard has enjoyed close associations; and that the picture, with the accompanying gifts of books, scientific papers and other mementos, be gratefully accepted and duly recorded in connection with the recent observance of the Tercentenary of Harvard College". (A note on the picture in question, which gives an unusual view of Oxford from the Sheldonian Theatre, appeared in NATURE of December 12, p. 1005.)

In conjunction with its annual general meeting in May 1938, the Iron and Steel Institute is to organize a symposium on "Steelmaking". Particular attention will be given to acid and basic open-hearth processes. Further information can be obtained from the Secretary, Iron and Steel Institute, 28 Victoria Street, London, S.W.1.

A David Anderson-Berry Gold Medal, together with a sum of money amounting to about £100, will be awarded in July 1938 by the Royal Society of Edinburgh to the person who, in the opinion of the Council, has recently produced the best work on the nature of X-rays in their therapeutical effect on human diseases. A similar award will be made every three years. Applications for this prize are invited. They may be based on both published and unpublished work and should be accompanied by copies of relevant papers. Applications must be in the hands of the General Secretary, Royal Society of Edinburgh, 22 George Street, Edinburgh 2, by June 1, 1938.

The Annual Malaria Control Course for Laymen will be held at the Ross Institute of Tropical Hygiene, Keppel Street (Gower Street), London, W.C.1, commencing on June 21, at 10 a.m., under the direction of Sir Malcolm Watson, director of the Institute. The course lasts five days, and is designed for planters and mining engineers, but it will be of interest to all (including missionaries) who are proceeding to the tropics. Application to attend the course should be sent in as early as possible to the Organizing Secretary at the above address. Admission is free.

The Medical Society of Vienna will celebrate the centenary of its foundation in conjunction with the Union for Postgraduate Instruction on May 19–29.

The next congress of the Society of German Men of Science and Medicine will be held at Stuttgart in 1938.

A national medical council on birth control has been formed in the United States to control and supervise medical policies of the American Birth Control League, and to initiate, encourage and carry out appropriate scientific research in the medical aspects of birth control.

The American Association for the Study of Goitre offers the Van Meter Prize of 300 dollars and two honourable mentions for the best essays on experimental and clinical investigation of the thyroid gland. The award will be made at the next annual meeting of the Association, which will be held at Detroit, Michigan, on June 14. The MSS., which should not exceed 3,000 words, must be presented in English, and a type-written double-spaced copy sent to the secretary, Dr. W. Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than April 1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 376.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Effects of Traces of Metallic Ions on Films at Interfaces and on the Surface of Water

IT appears advisable at this time to direct the attention of workers in the field of surface chemistry to recent work on the effects of minute traces of metallic ions on the behaviour of monomolecular films on the surface of water, since serious consideration of such results brings into question some of the data published on monomolecular films, particularly those data on films formed by substances with acidic groups in the molecule, spread on a neutral or basic aqueous layer.

Early in 1935, while at the Johns Hopkins University, one of us (R. J. M.) noticed an apparently abnormal behaviour of monomolecular films of palmitic acid on fresh distilled water. A heavily paraffined brass trough and a film-balance of the Langmuir type were used. It was found that when water was distilled directly from a quartz still into the trough, and a force-area determination made on the palmitic acid within a few hours after the distillation, quite expanded *liquid* films were obtained ($a_0 = 25{\cdot}0$ A.^{2}), which collapsed at relatively low pressures. If, however, the water were allowed to stand overnight in the trough, or if the distillate had been first caught in glass vessels, the usual *solid* condensed films ($a_0 = 20{\cdot}5$ A.^{2}) were obtained. The effect of the glass vessel was correctly attributed to minute traces of calcium ions, but the contamination of zinc and copper ions from the paraffined trough was unfortunately overlooked. The peculiar behaviour of palmitic acid had been noticed earlier by Adam[1], who also was at a loss to account for the difference between what he called 'old' and 'fresh' distilled water. Due to the press of other work, the experiments were not continued further at the Johns Hopkins University, but have been resumed at the University of Chicago, where the troughs now in use are plated with gold, rhodium, or both, while the newer apparatus is being constructed of quartz.

Such effects have been known for years, as in the remarkable action of calcium ions on the interfacial tension between solution of oleic acid in benzene and sodium hydroxide solutions, found by Harkins and Zollman in 1925[2]; these effects are due to the formation in the film of various mixtures of the organic acid with its sodium and calcium or other similar soaps. The phenomenon was discovered by Bancroft and Clowes[3] in their work on the inversion of emulsions.

Recent work by Langmuir, Schaeffer and Miss Blodgett[4] has apparently identified the curious results of Myers with the formation of mixed copper and zinc soaps, caused by solution of the brass trough, though heavily paraffined. Langmuir has also indicated that minute traces of calcium ions convert stearic acid films into calcium stearate, as a result of which the area per molecule is 20 sq. A. as compared to a very large area on dilute sodium hydroxide. Also, they find that the films are solidified upon the addition of calcium, a fact noted earlier by Harkins and Zollman.

While Langmuir has *implicitly* emphasized the effect of dissolution of the brass trough upon the characteristics of monomolecular films, it appears worth while to point out the great significance of these effects of minute traces of metallic ions in some of the published or unpublished work on monomolecular and polymolecular films.

First, it seems reasonable to expect similar startling differences in the behaviour of films when proteins, lipoids and similar substances are examined. Thus, in the interpretation of published work, it is necessary to qualify conclusions regarding the behaviour of fatty acids, lipoids and proteins, when films of these substances have been examined near the neutral point or on the basic side of their isoelectric point, unless troughs of quartz or similar material have been used, and chemicals, free from bivalent or trivalent impurities, have been employed. In particular, unless suitable precautions have been taken, such films should be referred to not as 'stearic acid' or 'protein', but as "mixed copper and zinc (or calcium) stearates", and 'mixed proteinates'.

Secondly, in the future, research workers who examine films of molecules which contain acidic groups should operate in quartz, or at least *very* heavily paraffined glass troughs. Further, salts used in the substratum should be exceedingly pure, in order that the phenomena which are observed may not be caused by spurious quantities of bivalent or trivalent ions. In view of the expensive nature of quartz and the ease with which metal apparatus may be fashioned, we have undertaken, together with an extensive study of these ionic effects, a study of various electrodeposited metals to determine whether troughs other than quartz may be used without error. Preliminary experiments conducted by us have indicated that under certain conditions even paraffined glass vessels may contaminate solutions contained in them. At Cornell University, Nutting, Long and Harkins are beginning work with troughs made wholly of paraffin.

Thirdly, it may very well be that the negative results of many experimenters who have tried to correlate surface activity with other variables, such as hydrogen ion concentration, have been caused by the formation of insoluble calcium or copper compounds due to the presence of traces of these ions in the substratum. All studies on interfacial tensions in systems containing substances of this character must be qualified due to the presence of calcium ions from the glass apparatus employed. It is quite possible that there will be found a remarkable difference in the contact potentials of films, when great care has been exercised to remove these interfering ions.

In fact, only when strongly acid solutions have been employed, can we be reasonably certain that the presence of calcium or similar ions in the substratum has had no influence on the behaviour of the film. Gorter[5] has found large differences in the area per molecule of ovalbumin films when sodium or calcium ions are present in the substratum. From other papers of Gorter, in which a glass trough was used, it appears reasonable to conclude that this work was also done in glass.

Glucolysis without Phosphorylation in the Chick Embryo

DURING the course of last year, a preliminary communication[1] in these columns gave an account of experiments on the chick embryo in the first week of its development, which suggested that glucolysis proceeds in these young tissues without phosphorylation. We wish now to give further details strongly indicating that this is so.

As was there reported, the embryo exhibits a marked substrate-preference, attacking glucose and mannose, but not glycogen or the phosphorylated hexoses. When phosphorus-transporters such as adenylic acid or cozymase are added to embryo (intact or *Brei*) in presence of glycogen or hexosediphosphate, a certain breakdown of these substrates may occur, but it is always small, transient, and not regularly demonstrable. Nevertheless, aldolase (zymohexase), which converts hexosediphosphate into triosephosphate, is present in as active a form in the chick embryo as in mammalian muscle extract. Hence triosephosphate accumulates steadily so long as the experiment lasts. The failure of the embryo to carry hexosediphosphate breakdown further than this cannot be remedied by addition of cozymase and pyruvate; it must therefore be due to lack or inefficiency of the enzyme system effecting the change.

However, all the enzymes concerned in the breakdown of phosphoglyceric acid are present in the embryo. Dephosphorylation of phosphopyruvic acid by adenylic acid is found in full strength in the earliest stage examined (23rd hour), before the neural folds have closed. The Parnas reaction, however, occurs in full strength only from the 43rd hour (beginning of cardiac activity). Only creatine phosphate, never arginine phosphate, is formed. Esterification of glycogen can at no stage be demonstrated. All the enzymes of phosphorylation which could be demonstrated in the embryo at all could be had in cell-free extract, in sharp contrast to the glucolytic system proper. This fact is important when conclusions on glucose breakdown are drawn from the behaviour of extracts of muscle or brain.

The rate of glucolysis itself, on the other hand, cannot be affected by the addition or removal of any of the phosphorus-transporters. Nor could any esterification of glucose be observed in a wide variety of conditions. The relation of fluoride concentration to inhibition is also different according to the system studied. Thus at $M/200$ sodium fluoride, the conversion of phosphoglyceric to phosphopyruvic acid is completely suppressed, while the glucolysis of the same *Brei* at the same time is only 40 per cent inhibited. Inhibition by *dl*-glyceraldehyde is powerful and specific; it is not shown by other aldehydes (for example, propionaldehyde, pyruvic aldehyde, etc.). By dialysis of embryo *Brei*, glucolysis may be inactivated. It may then be restored up to 80 per cent by the addition of rather large amounts of glutathione (cf. the work of Geiger[2] on adult tissues), larger amounts than are required for the reactivation of methylglyoxalase. Further, if glucose and synthetic methylglyoxal, in sufficient amounts to saturate the enzymes, are suddenly given together to a fresh embryo *Brei*, the subsequent summation of lactic acid formation which occurs is almost perfect. Methylglyoxal, as obtained by chemical synthesis, is therefore not an intermediate in embryonic glucolysis.

The two routes of breakdown may be further elucidated by the combined use of hexokinase (the enzyme of yeast which phosphorylates glucose), and fluoride or glyceraldehyde. In all cases, inhibition by these substances is of the same order whether hexokinase is present or not. Glucose could never be shunted into the phosphorylation route, even by the addition of hexokinase to embryo *Brei* in which the cell integrity had been abolished.

All these facts, and those summarized in the previous communication, are brought together by the hypothesis that in the chick embryo there are two separate routes of carbohydrate breakdown:

(i) A non-phosphorylating glucolytic mechanism, very active, and closely bound to the cell-structure, in which
  (*a*) glutathione is necessary;
  (*b*) methylglyoxal, dioxyacetone and glycerol are not intermediates.

(ii) A phosphorylating mechanism closely similar to that in muscle, dealing with glycogen and hexosediphosphate, but of low activity because deficient at four distinct places:
  (*a*) the enzyme esterifying glycogen;
  (*b*) the enzyme system dismuting triosephosphate with pyruvate to phosphoglyceric and lactic acids;
  (*c*) lack of adenylpyrophosphate;
  (*d*) lack of cozymase.

It would thus appear that in early embryonic development the phosphorylation machinery has not yet been fully laid down, and it is of interest that a similarly incomplete system has been described for some tumours[3]. Whether the non-phosphorylating glucolysis here described is the same as that suspected[4,5] in adult tissues such as brain, heart muscle, etc., remains for further investigation.

Lastly, attention may be directed to a correlation which seems to exist in embryo, brain, tumour, etc., between (i) relatively high anærobic glycolysis,

(ii) preference for glucose as substrate without the addition of hexokinase, (iii) sensitivity to glyceraldehyde inhibition, (iv) inefficiency of phosphorylation, (v) the Pasteur effect without the Meyerhof cycle.

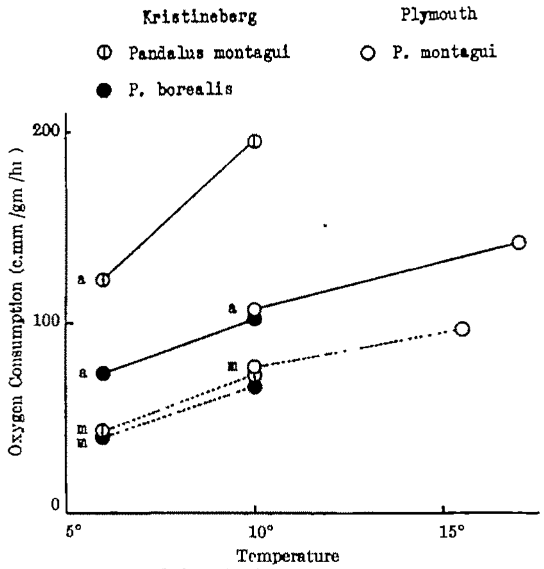
Rate of Tissue Metabolism of Marine Cold-blooded Animals in Different Latitudes

IN previous communications to NATURE[1] the activities and metabolism of arctic and English marine invertebrates were compared. It was shown that English species consume more oxygen, at the temperatures at which they live, than nearly related arctic species at the lower temperatures of their habitats. Since the locomotory activities of the English species are apparently no greater than those of their arctic cousins, the hypothesis was proposed that the greater oxygen consumption of the former is due to a greater non-locomotory metabolism. We have now tested this hypothesis for prawns living in the two waters by measuring the oxygen consumption of thin isolated muscles as well as that of the whole animals. The dorsal extensor muscles of the abdomen were used.



a, whole animals; *m*, isolated muscles.

Fig. 1.

Fig. 1 shows that *Pandalus borealis* from the cold water at Kristineberg[1] and *P. montagui* from Plymouth fully bear out the hypothesis. The oxygen consumption values for the whole animals fall on a single curve rising with temperature, and those for the muscles fall on another single curve parallel to the first. At every temperature the excess oxygen consumption of the whole animals over that of the muscles is the same.

But for *Pandalus montagui* from Kristineberg the situation is not so clear. Fig. 1 shows that while the oxygen consumption of its isolated muscles is almost identical with that of the muscles of *P. borealis*, the oxygen requirements of whole animals of the former species are almost double those of the latter. This suggests greater activity. Indeed the oxygen consumption of whole animals of *P. montagui* at the low temperatures of Kristineberg is seen to be as great as, or greater than, that of the same species at the higher temperatures of Plymouth.

In other ways, too, *Pandalus montagui* from Kristineberg behaves as a different physiological variety from the same species at Plymouth. The heart and scaphognathite rates at Kristineberg and at Plymouth show differences parallel to the oxygen consumptions of the whole animals in the two localities. Moreover, the Kristineberg variety will not survive an aquarium temperature above 11°, whereas the Plymouth form can be kept alive at 17°.

These results will be published in the *Proceedings of the Zoological Society*.

Effect of Ultra-centrifuging on the Egg of *Ascaris megalocephala*

EGGS of *Ascaris megalocephala* (= *equorum*) var. *monovalens*, like those of *Ascaris suum*[1], may develop normally after being subjected in the uncleaved condition to great centrifugal forces over long periods.

However, cytological examination of eggs which have been kept in the air turbine ultra-centrifuge at 150,000 times gravity until after control eggs have undergone several cleavages, shows that the nucleus has divided, but no cleavage of the cytoplasm has occurred. If one cleavage has been suppressed, there are four centrosomes and four chromosomes in the egg cell at the next metaphase (Fig. 1). In most of such cases the chromosomes are undiminished, but frequently diminution has occurred (Fig. 2). Such tetrapolar mitoses usually result in four cells, in all of which chromatin diminution has taken place before the next division is completed. Very rarely, the cleavage planes are so oriented that one of the resulting cells contains most of the material from the animal pole of the egg; chromatin diminution may take place in this daughter cell but not in the others. If two cleavages have been suppressed, there are eight centrosomes and four nuclei (eight chromosomes) in the egg cell. When such eggs are in metaphase, all the chromosomes have undergone diminution. In a few late prophases, however, all the chromosomes appear to be undiminished.

It seems clear that Boveri's explanation[2] of chromosome diminution, although valid in its reliance on cytoplasmic rather than nuclear control, is inadequate for the observations reported here. The mere presence of an inert material which either prevents (or causes) diminution can not account for the fact that it may take place in eggs when cleavage has been suppressed, although nuclear divisions and, presumably, other changes have occurred. It is these other changes which take place independently of cleavage but ordinarily correlated with it, to which attention must be turned in seeking an explanation; therefore, the following hypothesis is suggested: Chromatin diminution in *Ascaris megalocephala* is caused by the formation of 'diminisher', D, during the early cleavages of the egg. This 'diminisher' is produced from a cytoplasmic substance, S, which is more concentrated at the pole (which normally gives rise to somatic cells only), than at the anti-pole (which normally gives rise to both somatic and germinal cells). S changes to D slowly, but, before the concentration of D can become critical, the first cleavage usually occurs, thus segregating the greater portion of $S \rightarrow D$ into the polar cell (AB) which is destined to undergo chromatin diminution when it divides or at the next following division of its two daughter cells (A and B). The smaller portion of $S \rightarrow D$ is passed into the antipolar cell (P_1), but, before the concentration of D becomes critical, the cell divides (into P_2 and $EMSt$), most of $S \rightarrow D$ going into one of the daughter cells ($EMSt$) which undergoes chromatin diminution, the other (P_2) remaining undiminished.

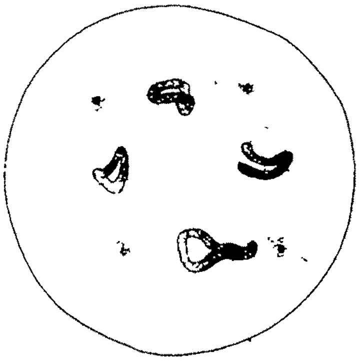

Fig. 1.

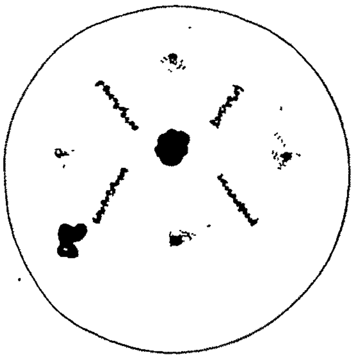

Fig. 2.

This differential partition of $S \rightarrow D$ is repeated until there is none, or at any rate, not enough, left in the primordial germ cell to cause chromatin diminution. Neither S nor D are to be identified as any visible inclusion in the cytoplasm. The process $S \rightarrow D$ is not disturbed by centrifuging, so that when the first cleavage has been suppressed by centrifuging, the concentration of D may become sufficient to cause diminution before the multipolar cleavage segregates the greater part of $S \rightarrow D$ into one (or more) cells. Even when such cleavage does take place, diminution usually follows in the four (or, less frequently, three) cells which result. If both the first and second cleavage are suppressed, diminution usually takes place in the uncleaved egg.

Diminution, then, is an example of chemo-differentiation; the rate of formation of the 'diminisher' depends upon the different concentration of the material producing it, in various regions of the cell. During cleavage, these regions are isolated by cell division, so that the process may occur in one daughter cell and not in the other.

This investigation was aided by grant from the Rockefeller Foundation for research in cellular biology.

An Air-borne Plant Virus

In a recent publication[1], an account is given of an unusual plant virus which is found in the roots of normal-looking plants of different species growing in the insect-proof glasshouse under conditions usually considered proof against virus infection. It is shown that this virus is water-borne to the soil, whence it reaches the roots of the plants.

The fact that the virus could still be detected in the roots of tobacco plants growing in autoclaved soil and watered only with boiled tap water, suggested that there was an alternative method of spread for the virus. Experiments were therefore planned to find out if the virus was also air-borne. Three types of suction apparatus were employed to test the air of the glasshouse. The first two were unsatisfactory, and gave negative results. The third type, designed by Mr. J. P. Doncaster, consisted of an electric pump connected by rubber tubing to six gas-washing bottles placed in different parts of the glasshouse. Each bottle contained a pad of moist cotton wool through which the air of the glasshouse was drawn. The cotton wool was tested for virus at 48-hour intervals by rubbing it on to the leaves of the French bean (*Phaseolus vulgaris*), which is an extremely sensitive test plant for the virus. This method was more successful, and, in three separate experiments, the virus was isolated from the cotton wool pads.

It is not perhaps surprising that such a minute virus (average particle diameter, 20–30 millimicrons), and one capable of withstanding complete desiccation, should be present in the air of the glasshouse. The interesting fact is rather that the virus should be able to spread by this means, without the aid of an insect vector or any apparent wound in the host plant. The smallest quantity of virus which reaches the soil seems eventually to enter the roots of a plant growing therein.

This discovery of an air-borne plant virus may possibly throw light on the mode of dissemination of other plant and animal viruses which are spread by some means at present unknown.

I have much pleasure in acknowledging the valuable assistance given me by Mrs d'Oliveira in carrying out these experiments.

Cultivation of *Histomonas meleagridis* from the Liver Lesions of a Hen

'Blackhead' (entero-hepatitis), a widespread and generally fatal disease of turkeys, was attributed to a protozoon, *Amœba meleagridis*, by Theobald Smith[1]. Later, Tyzzer confirmed its presence in cæcal lesions and renamed it *Histomonas* (gen. nov.) *meleagridis* Smith[2]. Although there is no difficulty in infecting young chickens experimentally with *H. meleagridis* (Tyzzer[3]) the disease produced is not severe, and the chickens soon recover clinically, though they may remain 'carriers', passing Protozoa in their fæces, for long periods. Theobald Smith[4] saw *Amœba* (= *Histomonas*) *meleagridis* in liver sections from diseased fowls, and Tyzzer[5] found similar lesions in a two-year-old hen. Although Drbohlav[6] and afterwards Tyzzer[7] cultivated *Histomonas meleagridis* from the cæcal discharges of experimentally infected chickens, all attempts to cultivate the parasite from diseased tissues from either turkeys or chickens failed (Tyzzer[7]).

Hitherto, the disease had been considered rare in mature fowls, but during the past year it appears to have occurred in several localities in England amongst laying stock, and in chickens on the farm belonging to one of us (H. P. B.). On December 3, 1936, we received a Rhode Island Red hen from a farm in Shropshire. Examination revealed focal necrosis of the liver and cæcal lesions which were macroscopically and microscopically similar to those occurring in turkeys suffering from 'blackhead'. Material taken with aseptic precautions from the necrotic areas in the hen's liver was inoculated into a tube containing an inspissated whole-egg slope covered with inactivated horse-serum diluted 1 : 8 in Ringer's solution to which a little solid, sterile rice starch had been added. Other similar tubes were inoculated with cæcal contents and scrapings. On incubation at 37° C., *Histomonas* appeared within 24 hours in the tube inoculated from the liver lesions. This strain of *Histomonas* from the liver is now in its twelfth subculture and is growing excellently on the above-described medium and on other media. In addition to *Histomonas*, the cultures contain a mixture of bacteria. These may be contaminants introduced when the primary inoculation from the liver was made, or, more probably, bacteria present in the lesion. Although according to Smith[4] bacteria are rare in liver lesions of turkeys killed at the height of the disease, they are not unknown, and they are not rare in smears made from the liver a few hours after death. It is possible that the presence of compatible bacteria has made the cultivation of the parasite possible. Cultures were made from the liver lesions of three turkeys, but these remained sterile bacteriologically and were negative for *Histomonas*.

The above-described strain of *Histomonas* from the hen's liver ingests starch and bacteria, and both flagellate and amœboid forms occur. It appears similar morphologically to the strains isolated from cæcal discharges by Tyzzer[7].

In the tubes inoculated with cæcal content and scrapings from the cæcal wall of the hen, *Blastocystis*, *Trichomonas* and *Chilomastix* appeared, but *Histomonas* was never seen; the growth of *Blastocystis*, however, was very heavy.

Effects of Colchicin and of *Viscum album* Preparations upon Germination of Seeds and Growth of Seedlings

THE investigations of A. P. Dustin and his school[1–5] have revealed an elective and extremely powerful karyokinetic action of the alkaloid colchicin upon the cells of certain specific organs and, in general, in all the germinative zones of animals, as well as upon the malignant tumours of the same. Dustin has also shown that this karyokinetic impetus is followed by an equally energetic karyoclasic effect upon the same tissues, and that this effect is specially marked in tumour cells, which are ultimately caused to collapse to a great extent under the influence of this alkaloid.

In a previous communication[6], I have given an account of the effects of several *Viscum album* preparations—containing as one of their active principles the alkaloid viscalbin (Leprince)—on plant tumours of the crown gall type (phytocarcinomata) which regressed and collapsed to a very marked extent when treated with these preparations.

In the preliminary experiments outlined in this note, I have investigated, at the suggestion of Prof. A. P. Dustin, the extent to which a parallelism can be found between the reactions observed in animals treated with colchicin and between the responses of plants treated with the same substance. I have also tried to ascertain whether these responses can be stimulated or inhibited by simultaneous applications of different preparations of *Viscum* according to their content of the above mentioned alkaloid.

Pure line Wilhelmina wheat, kindly given me by W. H. Parker of Cambridge, was germinated on filter paper in Petri dishes. 3–5 ml. of aqueous solutions of colchicin (Merck) or a dialysate of *Viscum* (Zyma)—free from the alkaloid viscalbin—or the pressed sap of *Viscum*, rich in viscalbin (kindly prepared and preserved in an atmosphere of carbon dioxide according to my prescription, by Zyma, Ltd.; Nyon), or a combination of one or the other of these *Viscum* preparations with colchicin were added daily to the Petri dishes. The technique used was otherwise the same as that described in previous communications[7,8]. No tables and measurements can be given here, but the following remarks are based both upon these and the general behaviour of the seedlings throughout the experimental period.

The experiments have shown that, in the concentrations used, colchicin exerts at the beginning of its application a definite stimulating effect on the rate of development of the roots and root-hairs. This effect is followed in 5–8 days by a very marked depression of the growth-rate of the roots, and in another day or two their growth is completely arrested. The growth-inhibiting influence of colchicin on the shoots begins even earlier. Synergetically, a *dialysate* of *Viscum* (containing no alkaloid) added to colchicin had, from the beginning to the end of the experiment, a more powerful growth-inhibiting action than the same quantities of either dialysed *Viscum* or colchicin, being applied separately. The simultaneous administration of colchicin and of the *pressed sap* of *Viscum* (containing the alkaloid viscalbin) had no such effects, and actually increased, in one of the concentrations used, the total weight of the shoots as compared with that of the seedlings treated with either *Viscum* sap or colchicin alone. Similar observations were made as regards the relative growth-rate of the roots.

The most specific effects of colchicin appear to consist, however, in (1) a bulbous hypertrophy of the root-cap, indicating an enhanced activity of the caliptrogen; and (2) a bulbous hypertrophy of the coleoptile and the thickening of its walls, accompanying the lignification of certain parenchymatous elements. The resistance thus presented by the coleoptile to the elongation and breaking through of the shoot also appears to cause the mechanical compression of this last, resulting in a bulbous deformation of the bases of the shoots.

These findings are further supported by the cytological examination of the regions affected, and appear to give, in the present state of the investigations, evidence of a parallelism between certain specific responses of plants and of animals when treated with colchicin.

The final interpretation of these observations must depend, however, upon further work.

Gamma Ray Excitation by Fast Neutrons

THE emission of gamma rays from substances traversed by fast neutrons was at first studied by Lea[1], using neutrons produced by bombarding beryllium with alpha rays. The subject was also studied by Kikuchi, Aoki and Husimi[2], using homogeneous neutrons from the deuteron-deuteron reaction. The same experiment has been repeated more accurately and using more elements than before, the result being shown in Fig. 1. [On account of the difficulty of finding space below the atomic number axis for the symbols of all the elements examined, a few only have been inserted as a guide.—Ed. NATURE.]

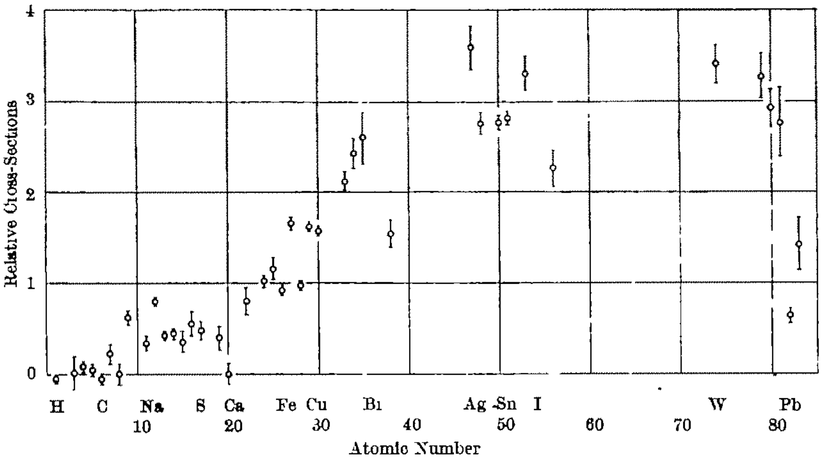

Fig. 1.

The experimental procedure was the same as before. In the present case, however, any substance near the neutron source was removed as far away as possible to suppress the secondary gamma rays which constitute a part of the background radiation to the counter, and also to avoid the possible change of energy spectrum of initially homogeneous neutrons.

In Fig. 1, the ordinate indicates relative atomic cross-sections, which were determined by the intensities of gamma rays from radiators so thin that the absorptions of neutrons and the emitted gamma rays were negligible. The cross-sections have not been corrected for the efficiency variation of the counter with the energy of gamma rays. The wall of the counter was made of aluminium, 3 mm. in thickness. In all cases, no gamma ray was observed after the neutron irradiation ceased.

Fig. 1 shows that the sudden jump of the cross-sections at Z (atomic number) $= 9$ is conspicuous, but discontinuities near $Z = 17$ suggested formerly can scarcely be recognized. It is quite interesting to note that the points are distributed roughly on a smooth curve which ascends in the region of lower atomic number and becomes horizontal at $Z = 50$, and probably falls again above $Z = 80$ (that is, in the region of radioactive elements). The deviations of points from this smooth curve are far in excess of the experimental errors.

These gamma-rays may be emitted by nuclear excitation by the 2·4 m.e.v. neutrons used, although we have no positive proof of this. Scarcity of secondary electrons with energy more than 2·4 m.e.v. is a strong support for this hypothesis.

The dependence of the cross-sections on the atomic number shown in Fig. 1 is different from that of absorption scattering cross-sections of fast neutrons obtained by Dunning[3]. From this fact we know that the emission of gamma rays is only part of the result of absorption and scattering of fast neutrons by nuclei. There may exist many other types of interaction; for example, disintegration of nuclei or the emission of β-rays from substances traversed by neutrons, which was reported by Kikuchi, Aoki and Husimi[4]. Absorption cross-sections of fast neutrons were determined by Collie and Griffiths[5], who detected neutrons by induced radioactivities by fast neutrons, and they obtained a constant value for several elements including copper, lead, etc. It is probable that these absorptions result from gamma ray emission, but the gamma ray excitation cross-sections in Fig. 1 are not constant for these elements. However, it must be taken into account that the energies of the neutrons are different in this case and from that of Collie and Griffiths.

It is natural to relate the emission of gamma rays to the production of slow neutrons by heavy nuclei. Collie and Griffiths observed that lead produces about the same number of slow neutrons as copper when reduced to the same number of atoms, but the cross-section for gamma ray excitation of lead is distinctly smaller than that of copper. The energy determination of emitted gamma rays is very interesting in this respect.

A detailed report of this work will be published shortly in *Proc. Phys. Math. Soc. Jap.*

Mechanical Tracer for Electron Trajectories

THE paths of electrons in vacuum devices have been in recent years objects of intensive study. The problem involves in general the solution of a partial differential equation for the field, and if the field is known, the solution of an ordinary differential equation for the motion of the electron. The first problem is usually solved experimentally, by constructing a large-scale model of the device, which is immersed in an electrolyte, and exploring the field with a probe. The second step is either to construct the electron paths by some graphical method in a map of the potential lines, or to introduce the data derived from probe measurements into certain approximative differential equations, as developed by H. Busch, W. Glaser, O. Scherzer *et al.*

An apparatus has been designed which makes it possible to trace the electron paths without mapping the potential field, and without calculation. Its principle, in the case of space-charge free electrostatic fields and plane electron paths, is as follows:

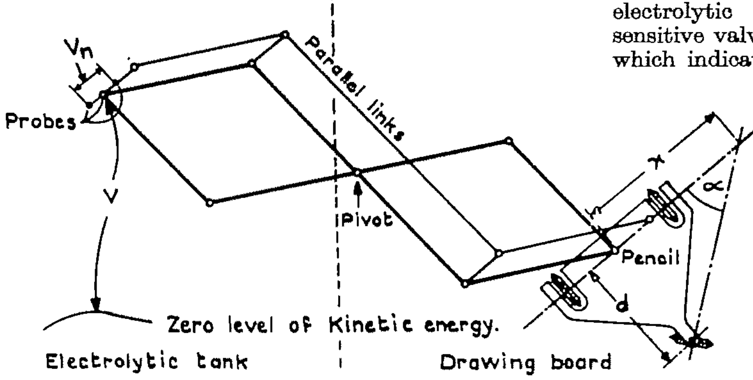

Fig. 1.

The curvature radius of the electron path is $r = 2V/E_n$, where V is the potential drop in which the electron has acquired its energy and E_n the field intensity normal to the path. In the electrolytic model the electron is represented by a probe and V is its potential with respect to the zero level of electron energy. E_n is measured by side probes, placed closely at either side of the main probe, at equal distances. The connecting line of these probes is kept always perpendicular to the path by the mechanism shown in Fig. 1.

The pencil tracing the electron path on a drawing board is carried by a trolley with three sharp-edged wheels. The pencil is connected with the main probe by means of a pantograph, and the trolley is linked with the side probes in such a way that their connecting line is always parallel to the leading wheels of the trolley, and therefore perpendicular to the path.

The trolley is steered by its third wheel, which can turn around a vertical axis. If the steering angle is α, the curvature radius of the pencil trace is $r = d \cot\alpha$. The pencil draws the true electron path if $\tan\alpha = k.V_n/V$, where V_n is the voltage between the side probes and k is a constant of the device. This steering angle is determined without any calculation by a special bridge, shown in Fig. 2:

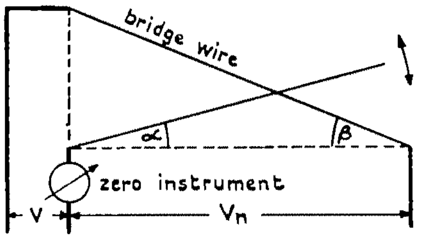

Fig. 2.

This bridge is set to zero if $\tan\alpha = \tan\beta . V_n/V$. If $\tan\beta$ is made equal to k, the steering angle is found by balancing V on a second bridge and simultaneously balancing the 'tangent bridge'. This angle is transmitted to the steering wheel automatically by means of a differential gear and parallel links. The trolley is moved on in small steps, keeping the bridges in balance all the time, and the pencil traces the path of the electron (or of any other charged particle).

In order to obtain the high accuracy required in electron-optical work, an improvement has been introduced in the bridge method as hitherto used in electrolytic model experiments. An extremely sensitive valve-wattmeter is used as zero instrument, which indicates zero, not if the slider of the bridge which indicates zero, not if the slider of the bridge has the same potential as the probe (a condition which cannot be fulfilled in general), but if the voltage vector between them is perpendicular to a fixed voltage chosen as 'base'. Thus one time-component of the potential vectors is sorted out. This has the advantage that it not only reduces the random error to negligible proportions, but also eliminates at the same time the systematic error, introduced by the polarization capacities at the electrodes.

The first apparatus of this particular kind has recently been completed in the Research Laboratories of the British Thomson-Houston Co. Ltd, Rugby. I wish to acknowledge my grateful thanks to my colleagues in the Research Laboratory, and to Mr. H. Warren, chief of the Laboratory, and the directors of the B.T.H. Co. Ltd. for permission to publish this note.

Condensation Coefficients of Various Substances

THE ratio of the number of gas molecules *condensing* on a surface per second to the total number *incident* on the surface may be defined as the 'condensation coefficient' (*f*) of the gas at the surface. It has usually been assumed that this coefficient has the value unity; in other words, that every gas molecule striking the solid surface remains attached to it for some time before returning to the gas phase.

Some years ago, however, it was shown[1] that the condensation coefficient of water vapour at a liquid water surface and that of ethyl alcohol vapour at the corresponding liquid surface were considerably less than unity ($f = 0{\cdot}036$ for water), and recently Lennard-Jones and Devonshire[2], having examined the problem of condensation at a crystal surface theoretically, have shown that values of *f* less than unity are sometimes to be expected.

I have now measured this coefficient for (*a*) iodine vapour at the surface of an iodine crystal, (*b*) naphthalene vapour at the surface of a naphthalene crystal, (*c*) camphor vapour at the surface of a camphor crystal, and (*d*) benzoic acid vapour at the surface of a benzoic acid crystal.

The results are shown in the accompanying table, which also includes the values of *f* for the liquids examined earlier and that for mercury as determined by Knudsen[3].

Substance	Condensation coefficient
Iodine	1·0
Naphthalene . ..	1·0
Benzene	1·0
Carbon tetrachloride .. .	1·0
Mercury	1·0
Synthetic camphor .	0·17
Benzoic acid . .	0·29
Water	0·036
Ethyl alcohol ..	small

Owing to the powdery surface of the solid benzoic acid, the true surface area must be greater than the apparent area. In obtaining the value of *f* given above, no allowance was made for this, so that the true value of *f* must therefore be smaller than that given.

It will be seen that, while *f* is equal to unity for iodine and naphthalene, it is comparatively small for camphor and benzoic acid. It is also to be noted that all those substances examined the molecules of which have a zero dipole moment have a condensation coefficient of unity; on the other hand, the substances the molecules of which have large dipole moments have small values of the coefficient *f*.

Molecular Distillation of Petroleum Lubricating Oils

IN some preliminary distillations of lubricating oils carried out in this laboratory, we have encountered results quite contrary to those anticipated, and as we believe them to be unlike any results hitherto reported, we deem them worthy of notice, even at this early stage of our investigations.

So far, the distillation of two oils, a Scottish shale oil and a Persian oil, using a specially designed molecular still, has been carried out. This still is based on the principles set forth by Hickman and Sanford[1]. The temperature control, and to some extent the pressure regulation, were not very constant (the temperature varied ± 3° C.), but even so the results are consistent. The most striking result, allowing for the lack of good temperature control, to our minds, is the inversion that has taken place in the change in the physical properties as we go up the temperature scale. Thus, instead of the first fractions showing low refractive indices and densities, they actually gave figures higher than those of the original oil, with gradually descending values from fraction 4 as the temperature is raised. The accompanying table makes this clear.

MOLECULAR DISTILLATION OF SHALE OIL NO. 55
(ALL CHARACTERISTICS AT 25°)

Fraction	Density	Refractive Index	Refractivity	Viscosity (centipoises)	Temperature (approx.)
Original oil	0·8935	1·5039	0·5640	51·86	
1	0·8961	1·5092	0·5682		40
4	0·9070	1·5151	0·5679	33·29	59
6	0·9018	1·5109	0·5665		60
10	0·8929	1·5038	0·5642	50·21	65
15	0·8805	1·4950	0·5622	66·25	95
Residue	0·8996	1·5064	0·5629	228·6	

We, ourselves, are specially interested in the carcinogenicity of these molecular distillates as compared with the products obtained by use of solvents. For example, all samples of petroleum oils we have treated with alcohol have provided residues of lower carcinogenicity than the original oil, but while index and density were always lower, viscosity was sometimes higher than that of the original oil. All these experiments have a bearing on the important question of the interrelation of index and viscosity to activity on injection, and thereby carcinogenicity when applied to the skin.

Variable Magnetic Moments of Cobaltous Compounds

IN the course of an investigation on the magnetism of cobalt compounds, we have found a notable difference between the magnetic moments of the blue and violet forms of *bis*pyridylcobaltous chloride, ($Co2PyCl_2$). The violet form, which is stable at room temperature, was first prepared in 1894 by Reitzenstein[1]; the blue form was obtained in 1927 by Hantzsch and Schlegel[2] by dissolving the violet form in chloroform and precipitating the substance by dilution with ligroin. The blue form can also be prepared by heating the stable form to 120°; it is unstable at room temperature and reverts to the violet form in a few days. Much work has been done on the absorption spectra, molecular weight, and conductivity of these substances[3].

Fahlenbrach[4] measured the susceptibility of solutions of cobaltous chloride ($CoCl_2$) in pyridine; below $-20°$ the $1/\chi, T$ curves were linear and gave $\mu_{\text{eff.}} = 5{\cdot}0$ Bohr magnetons over a range of dilutions. These red solutions probably contain $[Co6Py]^{++}$. From $-20°$ to $+35°$ the solutions were violet and the $1/\chi, T$ curve was not linear. Above 35° the solution was blue but the slope of the $1/\chi, T$ curve varied with dilution, and it was clear that a change in the magnetic moment of the carrier was taking place.

By using the pure solid compounds with two molecules of pyridine, we have found a large difference in moment between the two isomerides. The stable violet form gives at room temperature $\mu_{\text{eff.}} = 5{\cdot}34$. The blue form, prepared by heating to 120° for a few hours and cooling rapidly with solid carbon dioxide gave in successive experiments $\mu_{\text{eff}} = 4{\cdot}62$, $4{\cdot}58$ when measured at 20°. The true value may be slightly lower since conversion to the violet form soon caused a marked increase in moment, which rose to 5·3 in a few days.

The magnetic moment of most of the elements of the first transition series is close to that predicted for electron spin only[5,6]. Bivalent cobalt compounds are an exception to this rule and usually possess moments greater than that predicted for an electron spin of 3/2, namely, $\mu_{\text{eff.}} = 3{\cdot}87$. Some orbital component seems to be conserved and the degree of conservation may depend upon the symmetry of the environment of the magnetic atom[7]. If the violet form has the structure $[\text{Co4Py}]^{++}(\text{CoCl})_4^{=}$ then the cobalt atoms have a more symmetrical environment than in the unionized structure $[\text{Co2PyCl}_2]$, which may represent the blue form. This interpretation leads, however, to difficulties in connexion with the magnetism of other cobalt complexes which will be described elsewhere.

Dissociation of N_2^+

WITH reference to communications on valency and electronic structure published in this journal from time to time[1], we wish to direct attention to the spectrum of N_2^+ and particularly to the term $(C)\ {}^2\Sigma$ (3·52 e.v. above $(B)\ {}^2\Sigma$) found by Watson and Koontz[2] some time ago. This term, being the second excited level of ${}^2\Sigma$ type, is produced by the excitation of the unpaired $3s\sigma(2p)$ electron of the ground state $(X)\ {}^2\Sigma$, to the group $3d\sigma(3s)$.

The extrapolation of the vibrational levels shows that in this state N_2^+ dissociates into atoms one of which is excited by 11·28 e.v. (or 10·20 e.v. if the cubic term of the equation is employed). This value agrees perfectly well with the energy of excitation of nitrogen from its ground state $2s^2\ 2p^3\ {}^4S$ to the level $2s^2\ 2p^2\ 3s\ {}^4P$ (= 10·20 e.v.) which is indeed the lowest term in which N possesses a $3s$ electron. The energy of dissociation or formation of the molecule in this state is about 50 per cent bigger than that for the ground level. This shows that a more stable chemical linkage is produced in N_2^+ if the unpaired electron is removed to the next shell by excitation, the conditions being very similar to those in NO, discussed earlier[1]. There is, however, one significant difference. In NO the unpaired electron is in a promoted, or antibonding group. In N_2^+ the odd electron is a non-promoted or bonding electron.

This constitutes the first example which unambiguously shows that a single unpaired electron does not act as bonding but weakens the linkage, even if it is in a bonding orbital. Further, the large increase in dissociation energy as the molecule is excited from $(X)\ {}^2\Sigma$ to $(C)\ {}^2\Sigma$ state, directly contradicts the general identification of non-promoted with bonding and promoted with antibonding electrons. This evidence and other experimental results, which are mentioned earlier, are to our mind incompatible with the latter hypothesis.

A more detailed discussion will be given in connexion with considerations on the applicability of the Birge–Sponer method of vibrational extrapolation in a forthcoming paper, in the *Proceedings of the Indian Academy of Science* (Bangalore).

Recent Auroræ and Magnetic Disturbances

WITH reference to the displays of aurora on January 7 and February 3, reported in NATURE of February 13 and 20, pp. 277 and 318, the following further details may be of interest. The aurora of January 7 was noted by an observer in the vicinity of Preston, who reported seeing it between 19h. and 19½h. U.T. On this occasion, the magnetic records of Stonyhurst Observatory show a moderate disturbance between 18h. and midnight, the most notable movements being a fall of 27′ in westerly declination between 19h. 15m. and 19h. 32m., followed by a sharp rise of 28′ between 19h. 32m. and 19h. 42m., whilst horizontal force rose by 140γ between 19h. 22m. and 19h. 34m. and then fell by 180γ between 19h. 36m. and 19h. 43m. It may be noted that on this occasion the minimum value of *D* almost coincided with the maximum value of *H*. On February 3, however, these conditions were reversed, the minima in *D* and *H* being almost, but not quite, coincident in time. On this occasion, declination fell by 70′ between 18h. 58m. and 19h. 12m., whilst horizontal force fell by 225γ between 18h. 56m. and 19h. 09m., each element rising by corresponding amounts in the next ten minutes.

From fifty accounts received from observers of the aurora on the latter occasion, there can be little doubt that the most brilliant part of the display occurred during the easterly swing of the declination magnet. Of the fifty observers, eight first noted it between 18h. 40m. and 18h. 45m., and seven gave the end as 19h. 25m. or 19h. 30m., whilst no fewer than twenty-five reported first seeing it between 18h. 55m. and 19h., and twenty-nine gave the end as 19h. 10m. or 19h. 15m., the rest giving intermediate times for the first and last observations. It seems clear that whilst some observers noted the fainter glows near the beginning and end, the majority saw only the more vivid portions of the display. Two observers first noted it at 18h. 57m., two others note an increase in brilliance at 18h. 58m., one gives the end as 19h. 12m., and one other the duration as from 18h. 57m. to 19h. 12m.

This circumstance, of the display being chiefly during an easterly swing of the declination magnet, seems to apply also to the single local observation of

January 7, and a similar coincidence was noted by me in an observation of the aurora on December 20, 1930. On January 7 last, Mr. Craig in northern Scotland noted conspicuous features between 19h. 30m. and 19h. 45m., and a rapid decrease within a few minutes of the latter time, and it is worthy of note that another sharp fall of 14′ in declination was recorded from 19h. 35m. to 19h. 45m., after which minor oscillations occurred.

These observations seem to indicate that the aurora is chiefly manifest whilst a current of negatively charged ions is traversing the upper atmosphere in a direction with a south to north component. If the direction is north-east, the horizontal force would fall concurrently with the declination; whilst if it is north-west, the opposite condition would hold. It would be most useful if observers of the aurora would make careful note of the times when important changes take place, and especially of the time when the phenomena fade out. To get the time of actual commencement of a display is more difficult, as it will in general have been in progress for some time before being noticed. As the same disturbed region of the sun to which both the recent displays must be attributed will be on the central meridian on February 26, and was at the time of writing (February 20) showing a spot just inside the eastern limb, there is a possibility of a recurrence of the phenomena after the 27-day interval, on March 2, and it will be well worth while to keep a look-out on that evening, and on the preceding and following ones. It may be mentioned that the night sky was observed to be unusually bright with auroral light on February 6, 23h.—24h., February 9, 21h., when clouds prevented further observation, and on February 10, 23h.—24h., on all of which occasions moderate magnetic disturbances were in progress.

Stonyhurst College Observatory,
Near Blackburn.
Feb. 20.

Points from Foregoing Letters

THE presence of traces of calcium, copper and zinc affects considerably the properties of surface films, and Dr. R. J. Myers and Prof. W. D. Harkins consider that the results of many previous experiments reported in the literature (apart from those carried out in strongly acid solutions) are likely to have been vitiated by such contamination. They advise future investigators to use quartz or very heavily paraffined glass troughs, and to make sure that all salts are exceedingly pure.

Further experiments supporting the view that the oxidation of glucose to lactic acid can proceed in the chick embryo without the intermediate mechanism of phosphorylation are adduced by Dr. J. Needham and H. Lehmann. In this reaction, glutathione is necessary. The ordinary phosphorylation mechanism of carbohydrate breakdown operating in muscle through the intermediary of hexosediphosphate, is but of low activity in the chick embryo.

Prof. H. Munro Fox and C. A. Wingfield have measured the oxygen consumption of isolated muscles of prawns from different latitudes to test the hypothesis that the greater oxygen requirements of English compared with arctic invertebrates, each at the temperature of their habitat, is due to a higher non-locomotory metabolism in the former.

Diagrams showing the effect of ultra-centrifuging on the eggs of the horse round-worm are submitted by Dr. R. L. King and Prof. H. W. Beams. The authors connect the diminution observed in the size of the chromosomes with the suppression of cleavage walls, and postulate the presence in the cytoplasm of a ‘diminisher’ causing diminution of chromatin.

Dr. Kenneth Smith describes the discovery of an air-borne plant virus. This is the first time a plant virus has been shown to spread in this way.

Drs. H. P. Bayon and Ann Bishop report the cultivation *in vitro* of the protozoon *Histomonas melagridis*, from the liver of a diseased chicken showing symptoms similar to those occurring in turkeys suffering from ‘blackhead’. This disease is generally attributed to *Histomonas*, but the parasite has not yet been found in the liver of turkeys nor has it hitherto been successfully cultivated *in vitro*.

Relative cross-sections of 41 elements for gamma ray excitation by 2·4 m.e.v. neutrons have been determined by H. Aoki. The cross-sections plotted against the atomic number are distributed roughly on a smooth curve which rises with atomic number in the region of lower atomic number and probably descends again when the atomic number exceeds eighty.

An apparatus for tracing the paths of electrons in electrostatic fields is described by Dr. D. Gabor. The tracing pencil is moved mechanically on a drawing board, according to indications derived from probe measurements in an electrolytic model. Special precautions are taken to avoid the error introduced by polarization phenomena.

The unusual behaviour of certain petroleum lubricating oils on distillation is described by R. Lyth, who finds that the fractions first distilled have higher densities and refractive indices than the fractions that distil at higher temperatures.

A difference in the magnetic moments of the violet and the blue forms of *bis*pyridylcobaltous chloride has been found by E. D. P. Barksworth and Prof. S. Sugden, who indicate its relation to the symmetry of environment of the magnetic atom.

A discussion of the correlation of the ground level and the second excited level of the molecule N_2^+, Dr. R. K. Asundi and Prof. R. Samuel state, shows that an unpaired electron weakens a chemical bond even though it is in a non-premoted or bonding orbital. They consider this as a further experimental proof against the identification of non-premoted and bonding electrons, and therefore as an argument in favour of Heitler and London's pair-bond theory of valency.

L. Havas finds that colchicin (the active principle of the autumn crocus) exerts at first a stimulating effect upon the rate of development of the roots and root-hairs of wheat seedlings, followed by inhibition. The effect of mistletoe preparations (with and without the active principle viscalbin), separately and in conjunction with colchicin, are described.

Research Items

Control of Secondary Sexual Characters in Birds

MUCH information regarding the secondary sexual characters of birds, their alteration by experimental means and their bearing on the theory of evolution is given in a summary by Dr. Emil Witschi (*Scientia*, 60, No. 11). Many cases of male and female plumage in birds and their alteration by injections or castration are cited. The variety of conditions indicates that male and female plumage types are not necessarily always secondary sexual characters. In some species, plumage types are controlled by genetic factors, in others by hormones from different glands. Gonad hormones appear not to influence seasonal dimorphism. The hypophysis releases small quantities of gonadotropic hormones during sexual inactivity and large quantities in the breeding season. Ovarian hormone inhibits the development of cock plumage, but thyroid hormone appears to do the same. Ornamental plumages render the individual less fit for ordinary survival, but sexual selection cannot be considered the cause of the basic variations from which sex dimorphism has arisen; nor does it throw any light on the complicated hormonal and genetical control mechanisms. It is suggested that the change from hormonic to genic control may have happened through the hormones acting as messengers from soma to germ plasm.

Primitive Arthropods

THE Cawthron Lecture for 1935, delivered by the late Dr. R. J. Tillyard, has recently been published by the Cawthron Institute, Nelson, New Zealand. The subject of the lecture, "Tracing the Dawn of Life further Backwards", is one of special interest since it embodies the results of recent palæontological discoveries among the ancient rocks of the Adelaide series. These were the outcome of many years of work by the late Sir T. W. Edgeworth David, and the rocks in question form the Proterozoic series of Australia. They are stratified deposits supposed to have been laid down in Pre-Cambrian times. Among the fossils disclosed, none is more remarkable than those described by David and Tillyard as belonging to the Arthrocephala. This name is given by them to a new Arthropod class which included creatures with four moveable head segments each bearing appendages. The address is accompanied by two plates which represent restorations of these creatures, and are taken from the original memoir lately published by the two writers mentioned.

Melanophores of the Paradise Fish

THE melanophores of the paradise fish, *Macropodus opercularis*, show two different phases in their reactions to light. The primary phase, according to G. Tomita (*J. Shanghai Sci. Inst.*, Sept. 1936), lasts from their first appearance in the embryo until the eyes have begun to function. In darkness the animals are pale, and in bright light they are dark. The expansion of the melanophores is related to the intensity of the light. The functioning of the eyes is followed by the secondary phase, in which in darkness or in light the fish are pale or dark to correspond with their surroundings, but the reaction becomes slower with increasing age. The destruction of the eyes in the early larvæ has no effect on the reactions in the primary phase, but later larvæ in the secondary phase when so treated revert to the primary phase. Similar reversion is exhibited also by the newly born young of *Lebistes reticulatus*, *Gambusia affinis* and *Xiphophorus helleri*.

Pest and Plant

UNDER this title, Messrs. A. G. Bebbington (Empire Cotton Growing Corporation) and W. Allan (Department of Agriculture, Northern Rhodesia) have a very interesting discussion (*Empire Cotton Growing Rev.*, 14, Jan. 1937) of a thesis previously enunciated in the *Review* by Sir Albert Howard that "insects and fungi are not the real causes of plant diseases and only attack unsuitable varieties or crops improperly grown". Against this dictum, Messrs. Bebbington and Allan marshal convincing evidence, from their experience in Northern Rhodesia, of cotton crops in which the damage from bollworm and stainer attack is clearly the greater as the suitability of the locality for the crop increases, as also the care expended in its cultivation. They show also that with one stainer, *Dysdercus fasciatus*, the governing factor in determining its ravages on cotton is the extent of the fruit crop available on its chief host plant in that locality, the tree *Thespesia rogersii*. With the other stainer, *D. superstitiosus*, the story is more complicated, because it has a series of short-lived plants as its hosts and these vary in different regions, so that the incidence of attack varies in the same season from region to region. In all cases, however, both with bollworm and stainer, they produce remarkably strong evidence that, whilst neglected and poor crops of cotton struggle through to harvest with little damage from these pests, side by side with them well-grown plants, instead of yielding good crops, may be nearly ruined by their depredations.

Dermatophyte Fungi

A CASE of maduromycosis, a fungus disease affecting the legs of human beings, has recently been described from Canada by Drs. R. M. Shaw and J. W. Macgregor (*Canadian Med. Ass. J.*, 33, 23–28; 1935). A clinical history of the disease, which is known as 'madura foot', is given, and the causal fungus has been identified as *Monosporium apiospermum*. Dr. Eleanor S. Dowding also examined the fungus, and her account follows that cited above (*ibid.*, 28–32). The mycelium has the swellings and 'racquet hyphæ' typical of many dermatophytes, and its conidiophores are undifferentiated from the other hyphæ when submerged in the medium. They have a typical erect habit, often with tapering sterigmata, when borne aerially. A species of *Geomyces*, isolated from soil in Alberta, though similar to some of the fungi causing maduromycosis, was found to be non-pathogenic. Dr. Dowding and Dr. H. Orr have also studied the peculiar 'mosaic fungus' which appears in certain tissues parasitized by ringworm fungi. They consider that it is due to the breakdown of the dermatophyte fungus *Trichophyton gypseum*.

The Sudbury Nickel Irruptive

In his third paper on the life-history of the great Sudbury intrusion-complex, W. H. Collins describes the evidence bearing on the age relationships of the 'younger granites' to the 'nickel irruptive' (*Trans. Roy. Soc. Canada*, (4), 29; 1936). Dr. Collins and his co-workers have been unable to reach positive conclusions as to the relative ages of the rocks under investigation, though in the case of the Murray granite there are good grounds for the inference that it intruded the norite of the nickel irruptive. The Creighton granite, however, presents many puzzling features. Locally the norite becomes fine-grained against the granite and at one place stringers of a black chilled equivalent of the norite penetrate the granite for five feet. On the other hand, a stringer of granite was found extending from the main granite-mass into the chilled norite; moreover, a series of crooked and branching dykes of porphyritic granite, up to eight feet across where they leave the Creighton granite, has been traced for forty feet into the norite. After a careful discussion of all the possibilities, it is concluded that the apparent contradiction can be accounted for only by the hypothesis that the Creighton granite, though really older than the nickel irruptive, was mobilized by heat and pressure so that it was enabled to flow into cracks developed in the cooling norite. Collins is unable to support this hypothesis by many well-authenticated examples of the same phenomena Reference may therefore be made to the fact that at the top of the Portrush Sill (near the Giant's Causeway) several occurrences have been found by N. Harris of veins of mobilized hornfelsed Lias which pass downwards into the chilled margin of the Sill from the roof. Other veins in the dolerite of the Sill consist of syntectic rocks derived from the hornfelsed Lias by metasomatism and transfusion due to the action of magmatic emanations from the dolerite magma (Nature, 138, 984, Dec. 5, 1936).

Recent Earthquakes at Helena (Montana)

The destructive shocks of October 18 and 31, 1935, have directed attention to the earthquakes of the sparsely inhabited State of Montana. Mr. F. P. Ulrich has given (*Bull. Seis. Soc. America*, 26, 323; 1936) a brief description of these earthquakes, and has also compiled a list of all known shocks since 1805. Semi-destructive earthquakes occurred on December 10 and 11, 1872, and December 20, 1908, and a destructive earthquake, felt over about 300,000 square miles, on June 27, 1925. After a period of inactivity, the recent series began on October 3, 1935. On October 12, a semi-destructive earthquake was felt at least 200 miles from its centre. It was followed on October 18 and 31 by destructive earthquakes, between which 506 slight shocks were felt, the total number in the series up to the end of March 1936 being 1,794. The two great earthquakes were felt over an area of at least 200,000 square miles. Visible waves were reported by several observers. After each destructive earthquake, the ground at Helena was left crossed by stationary waves, the distance from crest to crest being 24–28 in. and the maximum depth 2–4 in.

Negative Ion Formation

F. L. Arnot has found that in mercury vapour negative ions are frequently formed by a positive ion extracting two electrons from any negatively charged electrode to which they are driven. The resulting negative ion is repelled from the electrode. A new paper by Arnot (*Proc. Roy. Soc.*, A, 158, 137) extends this work to hydrogen, nitrogen, oxygen and carbon dioxide. In all these cases negative ions were formed by the new process described above. Only monatomic ions were found in hydrogen and nitrogen, oxygen gave monatomic and diatomic ions, carbon dioxide gave CO_2^-, CO^-, O_2^-, O^-, and C^-. No negative ions produced by electron attachment could be observed, though this process has in the past been assumed to account for negative ion formation. The probability of conversion of positive to negative ions increases with the incident kinetic energy of the ion incident on the surface. For 180-volt ions it lies between 10^{-3} and 10^{-5}. The energy distribution of the positive ions rebounding as negative ions from a nickel surface has been measured, and the 'accommodation coefficient' defining the fraction of the kinetic energy of the ion lost on collision with the surface has been determined. This coefficient is not single valued, but has a most probable value such that the positive ion after reflection retains a few volts energy. In the case of hydrogen, there are two maximum values of the accommodation coefficient.

Scattering of Protons by Protons

M. A. Tuve, N. P. Heydenburg and L. R. Hafstad (*Phys. Rev.*, 50, 806) have made a careful study of the scattering of protons in hydrogen gas The protons were obtained from a high-voltage accelerating tube driven by an electrostatic generator with special arrangements for steadying and measuring the accelerating voltage, which was varied from 600 to 900 kv. The scattered particles were counted by an ionization chamber and linear amplifier. The results are compared with Mott's formula, which assumes the inverse square law of force. At 600 kv. the numbers observed at all angles are about two thirds of the Mott values. At higher voltages, the angular distribution is markedly different from that given by the formula, and the authors were able to assure themselves that the anomaly was real and not instrumental. The field around the nucleus must differ strongly from the inverse square field at distances of the order 10^{-13} cm. A paper by G. Breit, E. U. Condon and R. D. Present (*Phys. Rev.*, 50, 825) investigates the nuclear field by wave mechanical methods, and shows that the observations agree with scattering by a 'potential wall' in which the symmetrical de Broglie wave is distorted in a way corresponding to an attractive force overpowering the Coulomb forces at short distances. The magnitude of the interaction determined agrees with that used by Bethe in the calculation of mass defects of light nuclei. It appears to be identical with the proton-neutron interaction as determined from the scattering and absorption of slow neutrons.

Absorption Bands in the Spectrum of ψ-Isocyanine Dyes

Dr. E. E. Jelley recently reported (Nature, 138, 1009; 1936) that 1 : 1′ diethyl-ψ-cyanine chloride exhibited a characteristic narrow absorption band and a fluorescence of wave-length very close to that of the absorption band, when it was precipitated from aqueous solution. This he considered to be due to the existence of the substance in a transitory molecular state, intermediate between the dissociated and crystalline states. Scheibe, Kandler and Ecker (*Naturwiss.*, 25, 75; 1937) find such an absorption band and accompanying fluorescence in aqueous solutions of 1 : 1′ diethyl-ψ-isocyanine chloride of certain concentrations, and believe it to be due to a reversible polymerization of ions of the dye. In support of this view they quote the fact that there is a considerable increase in the viscosity of the solution in the concentration range in which the narrow absorption and fluorescence occur. The polymerization is completely reversed by raising the temperature by about 30°. The phenomenon is much affected by dilution, when viscosity, absorption and fluorescence disappear together. In heavy water the position of the absorption band is the same as in ordinary water. The absorption spectrum of the dye when adsorbed on various surfaces such as glass, quartz, gypsum and mica has been examined, and whilst the narrow band is obtained in all cases, its position is slightly different from that of the band observed with aqueous solutions. The fluorescence is also slightly shifted. Freshly split fluorspar and polystyrol do not adsorb the dye.

Secretions of Essential Oils in Plants

IN a report presented at the Annual Conference of the International Faculty of Sciences held in London on January 29–30, Prof. J. Politis discusses recent work in his department in the National University, Athens, on the morphology and physiology of certain plant glands. Glands on the leaves and, to a less extent, on the stems of the true artichoke (*Cynara Scolymus*) are responsible for the characteristic bitter taste. The gland originates from a single epidermal cell. The cell divisions taking place during development are described in detail, and the mature gland is figured. The characteristic bitterness of *Jurinea mollis* is found to be due to secretions from glands located on the stem, leaf and under-surface of exterior petals and bracts. Their origin, development and mature structure are also described and figured. Glands have also been found on the cardoon (*Cynara cardunculus*). Reference is made to the physiology of the secretive process, and micro- and macro-chemical tests of the substance secreted are given in detail. No further clues to their chemical nature have so far been obtained, however, but the author considers these bitter substances are essential oils which have been derived from glycosides by enzyme action.

Pure Oleic Acid

ALTHOUGH oleic acid is perhaps the most common of the naturally occurring fatty acids, the pure acid is still one of the rare chemicals. Oleic acid always occurs in fats and oils associated with saturated acids and usually with varying amounts of linoleic acid and acids of higher unsaturation. The methods of purification usually start with olive oil and proceed through the purification of the lead and barium soaps, and they are extremely tedious. J. B. Brown and G. Y. Shinowara (*J. Amer. Chem. Soc.*, 59, 6; 1937) show that oleic acid of high purity may be obtained by direct crystallization of the acids of olive oil from acetone. The saturated acids are removed by precipitation at − 20°, and the remaining unsaturated acids are crystallized from acetone at − 60° four or more times, this treatment being followed by a partial crystallization of the resulting products from acetone at − 35° to remove small amounts of palmitic acid not taken out in the original treatment at − 20°. The three specimens obtained, distilled at 15 mm. pressure, all melted at 13·0°; the iodine numbers were 89·63–90·04, and refractive indices n^{20} 1·4585–1·4586.

'Marmite'

THE Marmite Food Extract Co., Ltd., London, E.C.3, has recently issued a booklet describing the medicinal uses of its well-known preparation, 'Marmite'. This autolysed yeast extract contains in 1 gram about 30 units of vitamin B_1 and is also a good source of vitamin B_2. Marmite has been found of value in diseases caused by a deficient intake of the B vitamins such as beriberi or pellagra, or when they are incompletely assimilated, as in alcoholic polyneuritis. Insufficiency of vitamin B is also associated with many vague conditions of ill-health, especially those accompanied by gastro-intestinal symptoms: whilst an increased intake is required during pregnancy and lactation. Sufficient evidence has accumulated during the last few years to demonstrate that Marmite possesses anti-anæmic properties. It has been found of value in tropical macrocytic anæmia, in the pernicious anæmia of pregnancy and in the anæmias associated with cœliac disease, sprue, malaria and hookworm infestation. It has also been used successfully in the treatment of certain cases of Addison's pernicious anæmia, probably because it acts as a source of the 'extrinsic' factor: it does not contain a substance of the nature of the liver active principle. The booklet contains a table of the recommended dosage in the different conditions for which Marmite is indicated.

Shape of Road Aggregate

IN *Road Research Bulletin* No. 2 (London: H.M. Stationery Office. 6*d.*) a novel research is described to discover a method of classifying the shape and measuring the dimensions of the material that is placed as a covering on the surface of roads. Rightly or wrongly, surveyors and road engineers have thought that flaky and elongated material is undesirable for road construction. Although there are no records of actual failures that can be directly attributed to flaky material, there is a widespread unanimity of opinion that this material is unsatisfactory. In the British Standard Specifications for rolled asphalt, for example, it is stated that the stones have to be "angular and not flaky", thus hinting that flaky material is inferior. The Department of Scientific and Industrial Research and the Ministry of Transport have co-operated in preparing the bulletin under notice. The shape characteristics of broken stone and other similar materials have been measured and practical applications of the methods devised from the results have been considered. In view of the fact that the degree of flakiness permissible in an aggregate must depend at present on the judgment of the engineer, and since, in practice, deliveries will normally be compared with 'approved samples', no limits governing the maximum percentage of long and flaky material acceptable have been suggested. It is pointed out that flakiness in a crusher-run aggregate commonly varies with size. This fact, which is obviously of importance, is generally overlooked.

British Industries Fair

THE range of scientific exhibits, or of exhibits having some specific scientific interest, at the Olympia section of the British Industries Fair, was this year wider than ever, and it becomes increasingly difficult, if not indeed impossible, each succeeding year to attempt anything like an adequate survey of the exhibits likely to be of direct interest to scientific workers or to other readers who have an interest in scientific matters. All that can be attempted within the necessarily limited space is to direct attention to certain novel features of this year's exhibits. Perhaps one general observation that may be made is that, as the years go by, one is increasingly aware of how scientific instruments, at one time only of academic or quasi-academic interest, are steadily invading the domain of industry and finding industrial applications not even dreamt of until recently.

The chemical industries were, as usual, well represented, and showed an extraordinarily varied range of products. A large section of the exhibit of Boot's Pure Drug Co. Ltd. was devoted to a biological display, showing in particular a complete X-ray outfit for assaying vitamin D preparations, such as 'Decrose' (glucose with calcium glycerophosphate and vitamin D). They showed, as new products of particular interest to medical men, 'Ovostab' and 'Luteostab', prepared from the active principles of the female reproductive organs. Among their exhibits, British Drug Houses, Ltd., showed, in the hormone group, 'Anahæmin', which is the anti-anæmic principle of liver. It is issued as a solution in ampoules and rubber-capped vials. The Gas Light and Coke Co. exhibited a 'Premix' emulsion, a slow-breaking emulsion of tar, adapted for treating clean-graded road aggregates in an ordinary concrete mixer, producing a material which can be laid cold and gives a non-skid road surface of great durability. On the stand of Thorium Ltd. were samples of electromagnetically concentrated monazite sand from Travancore, South India. This sand contains about 9·5 per cent of thoria and 60 per cent of other rare earths. It is the raw material for the production of thoria and thorium salts, especially the nitrate.

Among the new developments in the British chemical industry during the past year attention may be directed to the preparation of crystalline soda by a new process, the commencement of commercial production of oxalic acid and the manufacture of metallic magnesium. The development of oil from coal processes has continued, and an entirely new angle in this development is the production of methanol instead of petrol. Interesting developments in the dye-stuffs field are the introduction of a new range of dye-stuffs for leather, for which advantages are claimed, and of a new range of dye-stuffs for the direct dyeing of acetate rayon.

Coming to the scientific instruments section of the Fair, one may note what has been noted before, namely, the enormous advantage obtained from a combined exhibit and also, alas, the continued absence of some firms whom anyone familiar with British scientific instruments would expect to find represented. Nevertheless, great credit is due to the organizers of this section of the Exhibition for a most impressive and widely varied display. Chance Bros. and Co. Ltd. produced a striking effect by exhibiting under strong illumination a broken mass of optical glass as it leaves the pot. There was this year perhaps an even better display than usual of microscopes, photographic lenses, epidiascopes and cameras. In addition to their usual massive model, Ross Ltd. exhibited a classroom epidiascope. This instrument is designed for small classroom work and is very portable. It has a 500–watt lamp, and the change-over from episcope to diascope is instantaneous. The maximum 'throw' of the picture is about twenty feet. Charles Baker showed an 'introscope', an instrument for inspecting the interiors of boiler tubes, ship shaftings, oxygen bottles and aeroplane spars, etc. By means of this instrument, it is possible to illuminate and examine microscopically surfaces which cannot easily be inspected in other circumstances. The instrument is made in lengths from 2 feet up to 33 feet.

A remarkable camera was shown by W. Vinten, Ltd. This camera takes 3,000 pictures per second and holds 400 feet of film, which is exhausted in 2½ seconds. The movement is continuous and at top speed reaches 120 miles per hour, the spool centres rotating at 15,000 revolutions per minute. There is a battery of 38 lenses, mounted on a rotating disc which runs at very nearly the same speed as the film. This camera is being used, among other purposes, for the study of important experiments in high-speed engines.

Among the chemical balances shown by L. Oertling, Ltd., there was a prismatic reflecting microbalance, which gives direct readings to 0·001 mgm. on the scale at the top of the balance case. It is claimed that this is the only balance in the world to read direct to 0·001 mgm. The capacity of the balance is 10 gm. and it is being much used in cancer research and in other problems of micro-chemistry. Kalee Ltd. exhibited a new production, namely, a high intensity reflector arc lamp, for use in cinematography. It is claimed that this lamp provides maximum illumination with comparatively low current consumption. Among the distinguishing features of this lamp may be noticed the embodiment of a short-focus, elliptical mirror. This provides for light collection from a wide angle, and has a further virtue that it dispenses with the use of the usual condenser lens for the focusing of the light on the film. Very thin carbon rods are used, and the mountings for the carbon rods are similarly reduced in size, so as to give the minimum interference with the projected light. The revolving sector is placed between the mirror and the projection lens system, instead of in front of the lenses, and thus helps to reduce the quantity of light entering the lenses with detrimental heating effects. On the stall of Theodore Hamblin, Ltd., an exhibit of novel interest was a binocular polarizing pool gazer. It is well-known that, when a fisherman looks at the surface of a pool of water, light from the sun and sky is frequently reflected from it as a dazzling glare, which prevents objects in the water from being seen. By the use of the polarizing binocular, these reflections are eliminated, and the pool gazer has a clear view of what lies beneath the surface. One must not forget to direct attention to the great developments that have been made within the last year in the applications of 'Perspex', the synthetic product having the appearance and most of the properties of glass, without its defects, to which reference was made last year. A new method has been devised of making optical lenses from this material (see NATURE, February 20, p. 336), and it will be a matter of much interest to watch how far it can be used in optical instruments of precision.

On the whole, one's impression is that those industries which may be regarded as more or less specifically scientific are in step with the general advance of industry and, in particular, alive to the opportunities created for new and, in some cases, striking developments.

Figures of the Earth and Moon

A RECENT paper by Dr. Harold Jeffreys (*Mon. Not. Roy. Astro. Soc.*, **97**, 1; 1936) deals with some well-known articles by de Sitter (*Bull. Astr. Soc. Neth.*, **2**, 55; **4**, 129. Also *K. Akad. Wetens. Amst.*, **17**). De Sitter assumed hydrostatic stress in the earth's interior, and computed the ellipticity and related constants from the precessional constant. On comparing the results with the motion of the moon's node and perigee, the greater part of which can be explained by Brown's theory, there is a balance depending upon the figures of the earth and moon. The former was taken by de Sitter to be calculable from his theory, and the small balance he attributed to the moon's ellipticities. As Jeffreys points out, however, the assumption of hydrostatic stress in the interior does not agree with other data. For example, accepting his solution, the probable error of the difference between gravity at the poles and at the equator is 1 milligal (0·001 cm./sec.^{2}), but Heiskanen's ellipticity of the equator alone gives a variation of 38 milligals at the extremes. In addition, the relativity correction was applied by de Sitter with the wrong sign, a fact which he pointed out to Jeffreys about five years ago, and this produced errors in some of the constants.

Jeffreys deals with the problem in a very thorough manner, certain geophysical information being now available which was unknown to de Sitter, and arrives at some interesting results. Although de Sitter made use of erroneous data which rendered his theory of the figure of the earth a little unsatisfactory, nevertheless the main ellipticity effects do not show much departure from his theory. The ellipticity of the earth is found to be 1/296·38 ± 0·51, and the corresponding gravity formula is

$$g = 978{\cdot}051\ \{1 + (0{\cdot}005282 \pm 0{\cdot}000006)\sin^2\varphi - 0{\cdot}000007 \sin^2 2\varphi\}.$$

He thinks that the accuracy of the formula is genuine so far as the term in $\sin^2\varphi$ is concerned. Other formulæ may suffer from greater inaccuracies because the methods of analysis may fail to allow for other terms.

Dealing with the moon, Jeffreys finds that the ellipticity of the equator is only about one-sixth that of the disk, and from this he concludes that when the moon solidified it was in a state of free rotation, the period being 3·5 days. In "The Earth" (second ed., pp. 228–9) he finds that the moon last adjusted itself to the hydrostatic state when its distance from the earth was about 87,000 miles, and its period of revolution and rotation 6·3 days. However, as he points out, the solution providing 3·5 days is only an *ad hoc* hypothesis. La Place's suggestion that the excess ellipticity may be due to random changes during solidification is probably as near the truth as Jeffreys's hypothesis. Obviously further research will modify some of the results which have been attained.

Hydrides of Boron

IN the December issue of the *Berichte der deutschen chemischen Gesellschaft*, Dr. E. Wiberg reviews at considerable length the experimental evidence from which the structure of the puzzling hydrides of boron may be deduced. That considerable difficulty has been encountered during the last decade in formulating the electronic structure of these compounds will be apparent from the fact that such unsatisfactory devices as singlet linkages, polyvalent hydrogen, a co-ordination number of five for boron, electronic septets, even the sharing of *K*-electrons, a new but unexplained kind of 'electrostatic-electromagnetic' valency and inequality of the two boron atoms, have all been requisitioned at various times in order to find plausible explanations of the existence of the simple compound known, perhaps wrongly, as boroethane, B_2H_6.

Recent work has thrown new light upon this problem, which has been greatly simplified. The author brings forward both chemical and physical evidence to show that, instead of ethane, one should rather regard ethylene as the carbon analogue of diborane (boroethane), since it possesses an unsaturated character; but the analogy should not be pushed too far, since the boron hydrides are also acids. Their acidic character has been rather concealed by the fact that their salts are very easily decomposed by water, but they combine with ammonia to form true salts. Thus diborane combines with two and tetraborane with four molecules of ammonia to form salts, which are electrolytes when dissolved in liquid ammonia although water decomposes them. That they are indeed ammonium salts rather than ammines is shown by the fact that an ammoniacal solution of borontrimethylmonoammine is non-conducting. Thus diborane is a dibasic, tetraborane a tetrabasic acid, and they may be formulated thus: $H_2[B_2H_4]$ and $H_4[B_4H_6]$.

The unsaturated character of these hydrides has been proved by both spectroscopic and chemical evidence. Thus diborane and ethylene give similar absorption bands, where ethane shows none at all, in the region between 210 and 186 μμ. Moreover, when shaken with alkali amalgam, the boranes react additively with the alkali metals thus:

$$B_2H_6 + 2K = 2K^+[B_2H_6]^{--}.$$

A molecular weight determination deduced from measurement of its diamagnetic susceptibility shows that the borane molecule has not been ruptured into simpler molecules in this reaction. The resulting potassium salt can be sublimed unchanged at about 400° C., so that the bivalent negative *ion* $B_2H_6^{--}$ with an ethane-like structure is much more stable than the unsaturated 'ethylenic' molecule B_2H_6, for which the formula $2H^+ [BH_2 : BH_2]^{--}$ must now be adopted.

The unsaturated character of diborane accounts also for its reactions with water and with hydrogen chloride, since in both cases the additive products which are first formed split off hydrogen to produce a new unsaturated product; this then reacts further in the same way until we arrive at boric acid or boron polyhalides as final products. Some of the intermediate compounds have even been isolated. Similarly, the formula of tetraborane is written thus:

$$4H^+ [BH_2 : BH{\cdot}BH : BH_2)^{----}.$$

Two different groups of hydrides have been recognized, corresponding with the general formulæ B_nH_{n+4} and B_nH_{n+6}. At present, only the first members of each group have been investigated experimentally, but in both cases the chemical evidence has been supported by that based on measurements of parachor, dipole moments, magnetic properties and ultra-violet absorption spectra.

Plankton Research and Sea Fisheries

A RECENT publication by R. E. Savage and R. S. Wimpenny ("Phytoplankton and the Herring", Part 2 (1933 and 1934), *Min. Agric. Fish., Fishery Invest.*, Ser. II, **15**, No. 1 (1936), pp. 1–88. London: H.M. Stationery Office, 1936. 4*s*. 6*d*.) gives detailed information on the plankton conditions in the southern North Sea and their relations with the herring fishery in the years 1933 and 1934. This is a continuation of work already begun in 1921 and follows on a previous report for the years 1921–32.

The year 1933 was remarkable for unusually dense patches of the diatoms *Rhizosolenia styliformis* and *Biddulphia sinensis*. The former is associated with the current system in the neighbourhood of the south-west Dogger Bank Swirl; and the unusual degree of production in 1933 appeared to owe its origin to a strong incursion of oceanic bottom water, from the north, rich in nutrient salts. The arrival of the East Anglian herring shoals was delayed by these diatom patches in October 1933. A remarkable condition is recorded in May 1933, when a large area was covered with masses of the diatom *Coscinodiscus concinnus* to a depth of four feet, in which several guillemots and puffins were found floating dead. This was apparently being eaten by fulmar petrels.

Increasing attention to detail in this long-continued plankton programme is producing indications of new lines for research. The relation between the distribution and drift of the plankton with the water circulation is gradually being disclosed, as well as certain interrelationships between the phytoplankton and the zooplankton which call for further observation. Notable among these is evidence that higher proportions of the eggs and young stages of plankton animals are to be found within the diatom patches than in the surrounding areas. Adult plankton animals and herrings also appear to be massed against the edges of the phytoplankton patches. Evidence is forthcoming that the distribution of the young stages of the animals may be associated with the high oxygen content of the diatom patches.

The authors intend to investigate this problem further, but whatever be the true significance, it is clear that this continued routine research is developing on expanding lines which will lead to a better understanding of the biology of the plankton in the future. The work is carried on throughout in close collaboration with the hydrographers.

University Events

LONDON.—The title of professor of biochemistry in the University has been conferred on Dr. A. C. Chibnall in respect of the post held by him at the Imperial College—Royal College of Science.

The title of emeritus professor of mining geology in the University has been conferred on Prof. C. G. Cullis, on his retirement from the University professorship of mining geology at the Imperial College—Royal College of Science.

Dr. F. G. Gregory has been appointed as from October 1 to the University chair of plant physiology tenable at the Imperial College—Royal College of Science. Since 1931, he has been assistant director of the Research Institute of Plant Physiology at the Imperial College.

The following have been appointed fellows of King's College: Prof. F. A. P. Aveling, professor of psychology since 1931; Miss Agnes S. Paul, lecturer in classics since 1932; Col. G. S. Szlumper, assistant general manager of the Southern Railway, and a vice-president of the Engineering Branch of the Old Students' Association; Mr. S. J. Worsley, academic registrar and acting principal of the University.

Prof. Raymond Pearl, professor of biology in the School of Hygiene and Public Health of Johns Hopkins University, has been appointed Heath Clark lecturer for the year 1937.

The degree of D.Sc. in mathematics has been conferred on A. C. Offord, of University College, and that of D.Sc in physiology on Miss M. M. A. Murray, a recognized teacher at Bedford College.

OXFORD.—Prof. A. G. Tansley, Sherardian professor of botany and fellow of Magdalen College since 1927, is retiring under the age-limit as from July 31, 1937. Applications for the vacant professorship should reach the Registrar by April 17. The Board of the Faculty of Biological Sciences has recommended that the new professor should be primarily an ecologist.

The Nuffield professors, Prof. H. W. B. Cairns, Balliol, and Prof. R. R. Macintosh, Pembroke, and also Dr. S. Zuckerman, Christ Church, have received the degree of M.A. by decree.

Science News a Century Ago

Tunnels and Health

THE following extract is taken from a report issued on February 21, 1837, by Dr. John Ayrton Paris, Dr. Thomas Watson, Mr. William Lawrence, Mr. R. Phillips and Mr. W. Owen Lucas on the Primrose Hill Tunnel on the London and Birmingham Railway, which they had examined in order to ascertain the probable effect of such tunnels upon the health and feelings of the passengers: "We found the atmosphere of the Tunnel dry, and of an agreeable temperature, and free from smell; the lamps of the carriages were lighted; and in our transit inwards and back again to the mouth of the Tunnel, the sensation experienced was exactly that of travelling in a coach by night, between the walls of a narrow street The noise did not prevent easy conversation, nor appear to be much greater in the Tunnel than in the open air. Judging from this experience and knowing the ease and certainty with which thorough ventilation may be effected, we are decidedly of the opinion that the dangers incurred in passing through well constructed Tunnels are no greater than those incurred in ordinary travelling upon an open railway or upon a turnpike-road; and that the apprehensions which have been expressed that such Tunnels are likely to prove detrimental to the health, or inconvenient to the feelings of those who may go through them, are perfectly futile and groundless." This report was not published in a contemporary medical journal, but is to be found among the reports in the library of the Royal Society of Medicine

A similarly favourable report was issued the same day by Dr. John Davy and Dr. R. W. Rothman, and on February 19 by Dr. James Williamson on the Tunnel on the Leeds and Selby Railway.

Alexander Burnes in Sind

AT a meeting of the Royal Geographical Society held on February 27, 1837, a paper was read by Captain (afterwards Sir) Alexander Burnes (1805–41) on his exploration of Scindè (Sind). After describing the River Indus, and the character of the surrounding country, Burnes gave an account of the people. The inhabitants, he said, were chiefly Mohammedans, about one fourth being Hindus. Syúds and fakirs were respected to veneration; many doubtless were virtuous, but the bulk he feared were hypocritical fanatics. The mendicants were more numerous than in any other country in Asia. They could scarcely be called beggars, for they demanded tribute in crowds and by threats and with great arrogance. The Government was despotic and oppressive; trade and agriculture languished under it.

It was the disordered state of Scinde which led to the expedition of General Sir Charles Napier (1782–1853) in 1842 and the annexation of the province.

Clarke's Electrical Measuring Instruments

WRITING on February 28, 1837, from the Laboratory of Science, Lowther Arcade, London, to William Sturgeon, the founder of *Sturgeon's Annals*, E. M. Clarke said: "As almost every scientific inquirer is at present directing his attention to the construction of electric batteries, and as in my opinion there is no correct measurer of their relative merits, I beg leave to submit to the notice of your very numerous readers two instruments which I have constructed for that purpose."

The first of the instruments Clarke described he called a thermo-electrometer. It consisted of a length of platina wire about 1/90 in. in diameter stretched between two terminals supported on the upper edge of a scale marked in feet and inches. The current flowing from the battery was measured by the length of wire made red in darkness, or burned.

The second instrument was described as an electro-gasometer, the current being measured by the amount of gases given off when the current was passed from one platina plate to another in water. This instrument Clarke said he had constructed "from having seen a very imperfect one at the Royal Institution made out of a two-necked bottle with platina electrodes passing through the holes drilled in the graduated glass tube". Descriptions and sketches of the instruments are given in vol. 1 of *Sturgeon's Annals*.

An Investigation into Animal Magnetism

A CERTAIN M. Berna having set forth claims regarding animal magnetisms somewhat akin to those previously made by Friedrich Anton Mesmer (1734–1815), the author of the doctrine of animal magnetism, or mesmerism, the Royal Academy of Medicine, Paris, appointed a commission under the presidency of M. Roux to inquire into the claims of M. Berna. The first of the meetings of the commission took place on March 3, 1837, and the commission reported to the Academy in August 1837. The report was printed in the "Annual Register", 1837. In the concluding paragraph it said that with reference to M. Berna's claims: "Those facts which he promised to show us are all known to you; you know as we do that they are anything but conclusive in favour of the doctrine of animal magnetism, and that they can have no relation either with physiology or with therapeutics."

Education at Oxford

A LEADING article in the issue of the *British Annals of Medicine* for March 3, 1837, contains the following comment on contemporary medical education at Oxford: "Our readers cannot fail to have drawn some ominous conclusions from the facts detailed in the correspondence relative to Oxford, which has appeared in our pages. It is a fact, we believe, undeniable that several years ago the classes at that University were well attended, in the usual acceptation of the term, that of late the attendance has been gradually decaying and now threatens to convert the professorships into sinecures; that is, to take the professors away from Oxford, for we think this must soon occur if the signification of the term professor is not altered; as hitherto, at every university at home and abroad, so far as we can learn, the title of professor is alone bestowed on those who engage in the active duties of teaching literature and science. Even at present it does not appear that one half of the professors at Oxford ever lecture at all. These are melancholy facts, it may be admitted, but how are they to be remedied? A remedy can only be found by the agency of the professors themselves or by the agitation of those who are aggrieved. The former would effect the most speedy cure; their united complaint would not fail to be listened to by the Legislature. The Government could institute an inquiry by means of impartial agents."

Societies and Academies

London

Royal Society, February 18.

E. N. da C. Andrade and R. C. Parker: A standard source of sound and the measurement of minimum audibility. A source of sound has been constructed of which the energy output can be measured in absolute units. The air in a tube is maintained in vibration by means of a loudspeaker unit attached to one end: the other end is open, and serves as the source. The energy output is found by measuring the length of the traces of smoke particles at an antinode, the method being thus a very direct one. One of the difficulties is to ensure that a given current flowing through the speaker unit shall always produce the same amplitude. The source was calibrated in terms of the current supply by determining the currents corresponding to various measured amplitudes at fixed frequencies. It has been used to determine the least pressure variation detectable by the ear, under conditions free from background noise and unwanted reflections.

C. J. Milner: The magneto-resistance effect in cadmium at low temperatures. Apparatus is described for measuring the increase of electrical resistance of specimens of cadmium, at low temperatures, in magnetic fields up to 26 kgauss. At temperatures above 20° K., Kapitza's observation, that for strong fields a linear variation of resistance with field strength replaces the initial square law, was confirmed. At helium temperatures a new effect was found. In addition to the linear effect mentioned, a square-law increase was observed, producing a very large increase of resistance in pure specimens. The increase of resistance could be represented as $a.H^2 + b.H$, where b is constant, and a is inversely proportional to the residual resistance of the specimen. a is constant at the lowest temperatures, but falls rapidly above 4° K. to negligible values; b varies only slightly with the temperature. The a-effect is absent when the magnetic field is parallel to the current, and the curve then shows a saturation effect, at helium temperatures. It would seem that the a-effect has previously been observed, though not recognized, in other metals of the non-cubic groups: but that the effect is absent or much smaller in the cubic metals, copper, silver, gold and aluminium.

Edinburgh

Royal Society, February 1.

James Kendall: Ions and isotopes. No separation of isotopic ions was obtained by running a solution a considerable distance along a series of tubes; hence ionic mobility is fundamentally dependent upon *volume*, not upon *mass*. Many difficult separations, however, such as pairs of rare earth elements or radium from barium residues, were readily achieved by ionic migration. A slight separation of the isotopes of mercury by fractional electrolysis was obtained in 1923. Work on hydrogen was begun in 1930, but pure 'heavy hydrogen' was first isolated in America two years later.

A. Graham: Ciliary currents on the gills of some Tellinacea (Lamellibranchiata). The relationship between the lamellibranch *Solecurtus* and the Tellinacea, evident on morphological grounds, is stressed by the arrangement of the frontal ciliary tracts on the outer gills, which in both groups beat towards the ctenidial axis instead of to the free margin of the gill as normally. This supports the interpretation of the outer gill of Tellinacea as homologous with the supra-axial extension of other lamellibranchs and that of *Solecurtus* as a reduplication of the same structure.

Paris

Academy of Sciences, January 25 (*C.R.*, 204, 201–304).

Emile Borel: The imitation of chance.

Antonin Gosset and Léon Binet: The increase of the proportion of glutathione in the liver by treatment with sulphur compounds.

Jean Baptiste Senderens: The catalytic decomposition of halogen-substituted acetic acids, in liquid systems. Details of the decomposition products of trichloracetic, tribromacetic and dichloracetic acids when heated below their boiling points with various catalysts. The nature of the reaction varied with the catalyst; thus trichloracetic with thoria gave phosgene, hydrochloric acid and carbon monoxide, while with activated carbon the products were carbon dioxide and chloroform.

Maurice Gignoux and Franck Bourdier: The Rhodanian fluvio-glacial formations in the neighbourhood of Bellegarde (Ain) and the neo-Würmian ice period.

Marc Courtand: Left curves of the fourth order.

Max Eger: Canonical systems of an algebraical variety.

Jean Louis Destouches: Spaces with finite character.

Louis Pasqualini: The conditions of convexity of a V_p-1 variety of $p-1$ dimensions immersed in Euclidian space R_p of p dimensions.

G. Avakumović: Theorems relating to Laplace integrals on convergence boundaries.

Ny Tsi-Ze: The so-called circular transversal vibration of a hollow quartz cylinder.

Léon Beschkine: Corrections to be applied to the general theorems utilized in resistance of materials when the displacements are not negligible.

Emile Sevin: Cosmic radiation and the stars of the principal series.

Jean Cichocki: The latent energy of solid solutions.

Jules Géhéniau: The production of electromagnetic waves by means of neutrinos.

Albert Grumbach and Pierre Vidal: A new method of preparing semipermeable membranes. The copper ferrocyanide membrane is formed by a special technique on a glass filtering plate, after the pores of the latter have been reduced by deposition of gelatinous silica.

Marcel Pauthenier and Charles Martin: The limiting electric charge of very small particles.

Jean Crussard and Louis Leprince-Ringuet: Study with the large Bellevue electromagnet of the passage through screens of the particles of cosmic radiation.

Mlle. Suzanne Veil: Some batteries with unlike electrodes.

Mlle. Marguerite Perey: The spectra of barium and strontium.

Pierre Barchewitz: The absorption spectra of amines in the near infra-red. (6000–95,000 A.)

Georges Déchene: The extreme ultra-violet emitted by electrical discharges in air under reduced pressure.

T, Nicolas Panay. The continuous flame spectrum of potassium.

Paul Soleillet : The mean duration of life of the zinc atom in the state 2^3P_1 and the method of total absorption. Discussion of the interpretation of the experiments of W. Billeter.

Mlle. Yvette Cauchois : Weak emissions in the *L* spectrum of rhenium (75).

Pierre Auger, Paul Ehrenfest, jun., André Feorn and André Fournier : The angular distribution of hard corpuscular cosmic rays.

Jacques Errera and Pol Mollet : The (OH) band of monomolecules of alcohol in the region of 3μ.

Mme. Marie Freymann : The absorption spectra in the near infra-red of mixtures of amines and alcohols. The formation of ammonium compounds.

René Delaplace : The thermal conductivity of unsaturated hydrocarbons at low pressure.

Hubert Forestier and Richard Lille : The variation of the catalytic power of ferromagnetic bodies at the Curie point. Studies based on the reaction $CO_2+H_2=CO+H_2O$ in the presence of various ferromagnetic oxides as catalysts. The variations of the catalytic activity of the three oxides used were shown to be related to the electronic phenomenon at the Curie point.

René Perrin and Jean Lamberton : Contribution to the study of the equilibria between metals and slags. Discussion as to the applicability of the law of mass action to metals in contact with slag.

Emile Cherbuliez and Mme. Anna Herzenstein : The detection and estimation of colloidal sulphur and of polysulphide sulphur in sulphurous waters.

Georges Darzens and André Levy : New researches on the condensation of dichloracetic ester with ketones and aldehydes by magnesium amalgam.

J. D. H. Donnay and David Harker : The generalization of the law of Bravais.

B. Choubert : Graphical expression of regional metamorphism.

Franck Bourdier : New observations on the extension of the ancient glaciers in the lower valley of the Isère.

Gérard Waterlot : The age of the folds and faults of the Cambrian massif of Rocroi.

Louis Dubertret : Fragments of tectonic breccia at the surface of the green Syrian rocks.

Henry Hubert : Observations of detail on the bar of Dahomey.

Pierre Gavaudan : The final condition of the nucleole during mitosis and its general relations with the thymonucleic chromatin.

Theodor Solacolu and Démètre Constaninesco: Tumours with neoplacic characters formed on plants by the action of β-indolylacetic acid.

René Souèges : The embryogeny of the Dipsacaceæ. The development of the embryo in *Scabiosa Succisa* L.

Alfred Balachowsky : The experimental rupture of the diapause in the caropcapse or 'vẹr des pommes' (*Laspeyresia pomonella*).

Gabriel Guignon and Mlle. Anne Raffy : The influence of the points of heating presented by the wings of diurnal Lepidoptera exposed to solar radiations on the power of flight of these insects.

Mladen Paić : The identification of the pigment elaborated by the diphtheria bacillus.

Maurice Doladilhe : A property of the viscous protein of syphilitic sera. It is shown that the substance imparting to a syphilitic serum characters of flocculation enabling it to be differentiated *in vitro* from a non-syphilitic serum, is localized in the viscous protein.

André Boivin and Mme Lydia Mesrobeanu : The nature and biological properties of the toxins produced by the Shiga bacillus and by the Flexner bacillus.

Cracow

Polish Academy of Science and Letters, December 7.

S. K. Zaremba : Remarks on the approximate integration of differential equations.

K. Koziel : Gibbs's formulæ for the ratios n_1 and n_2 of the areas of triangles.

A. Kotecki : New fluctuation bands in the spectrum of cadmium vapour.

Mlle. A. Wrzesinska : Influence of the concentration on the distribution of the intensities in the photo-luminescence spectrum of glycerol solutions of trypaflavine.

S. Dobinski and J. Wesolowski : The coefficient of viscosity of liquid selenium. The viscosity-temperature curve does not show the irregularities found some time ago by Pelabon in his study of the electrical conductivity of selenium. Liquid selenium belongs to the second class of associated liquids according to Andrade's theory of viscosity.

L. Marchlewski and Mlle. R. Grünbaum : Absorption of the ultra-violet rays by certain organic substances. (42) Datiscetin, morin and quercetin.

Mme. J. Dyakowska : Researches on the velocity of the fall of pollen of several species of trees.

S. Krzemieniewski and J. Kovats : Action of iron and of molybdenum on the fixation of nitrogen by *Azotobacter*.

Mme. Z. Malaszynska-Suchoitz : Cytological researches on the tegumentary glands of the crayfish, and considerations on the role of the plasmatic structures.

R. Towarnicki : Structure of the hooked apparatus in the anterior part of the body of the larva of the blowfly (*Calliphora vomitoria*).

Rome

Royal National Academy of the Lincei

(*Atti*, 23, 721–806 ; 1936).

W. Blaschke : Contribution to integral kinematics.

G. Zwirner : Integration of a matrix according to Volterra.

G. Lampariello : A theorem of statics of van den Dungen.

B. Finzi : Dispersion of a vortex in a plastic medium.

E. Frola : Certain integrals capable of resolving the dynamic problem of bent beams (1). The equation $(C(x)y'(x)')=-\lambda\,M(x)\sin\,y(x)\,;\,y(0)=y(1)=0(2)$.

G. Krall : Vibrations induced by inert and lightened loads which are in motion on a bridge.

L. Gialanella : Meridian observations of Jupiter and of Vesta in 1935.

L. Castelli : Equivalent widths and central intensities of absorption lines in the solar spectrum at the centre and at the edges.

G. C. Wick : Diffusion of slow neutrons.

P. Guareschi : Calculation of latent heats of evaporation.

G. Centola : Structure of acetyl cellulose soluble in acetone, or 'cellite'.

F. Penta : Fossil carbon in the Mesozoic of Longobucco in Calabria.

G. Landra : The tricocicloforus of Sergio Sergi and its first application. The use of this instrument for measuring dimensions of hair in anthropological studies is described.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, March 1

Museums Association, at 5.—Peter Holm: "The Old Town: a Folk Museum in Denmark".*

University of Leeds, at 5.15.—Prof. A. H. Gibson: "The Use of Working Models in Engineering".*

Royal Geographical Society, at 5.30.—G. C. Schluter: "On Safari in East Africa" (Geographical Film).

Swiney Lectures on Geology, at 5.30—(at the Imperial College of Science, Exhibition Road, South Kensington, S.W.7).—Dr. Frederick Walker: "Ice Ages" (succeeding lectures on March 3, 5, 8, 10, 12, 15, 17, 19, 22 and 24).*

King's College, London, at 5.30.—Dr. W. A. J. M. van Waterschoot van der Gracht: "The Sub-Surface Structure and the Sediments of the Great Basin of North-Western Europe (including the North Sea and Eastern Lowlands of England)" (succeeding lectures on March 2 and 3).*

Royal Society of Arts, at 8.—F. I. G. Rawlins: "The Physics and Chemistry of Paintings" (Cantor Lectures. Succeeding lectures on March 10 and 15).

Tuesday, March 2

Royal Society of Arts, at 4.30.—R. E. H. Baily: "The Anglo-Egyptian Sudan."

Gresham College, London, E.C.2, at 6.—A. R. Hinks, F.R.S.: "Studies of the Solar System" (succeeding lectures on March 3, 4 and 5).*

Institution of Civil Engineers, at 7—(at the Royal Geographical Society, Kensington Gore, S.W.7).—Symposium on "Research in Connexion with Motor Vehicles".

Wednesday, March 3

Institution of Electrical Engineers (Wireless Section), at 6.—Commander F. G. Loring, W. L. McPherson and W. H. McAllister: "A Survey of Marine Radio Progress, with Special Reference to R.M.S. *Queen Mary*".

Thursday, March 4

Royal Society, at 4.—Discussion on "Beta Transformations of Atomic Nuclei", to be opened by Prof. C. D. Ellis, F.R.S.

University College, London, at 5.30.—Prof. K. von Frisch: "The Sense of Hearing in Fishes".*

Chemical Society, at 8.—Prof. H. S. Raper, F.R.S.: "Some Problems of Tyrosine Metabolism".

Friday, March 5

Royal Society of Arts, at 4.30.—Dr. E. J. H. Mackay: "Excavations at Chanhu-daro".

Society of Public Analysts and Other Analytical Chemists, at 5.45—(in the Chemical Society's Rooms, Burlington House, Piccadilly, W.1).—Annual General Meeting.

Prof. G. Barger, F.R.S.: "The Alkaloids of Ergot".

Bedson Club (Armstrong College, Newcastle-upon-Tyne), at 6.30.—W. T. Astbury: "The X-Ray Interpretation of Protein Structure" (Thirty-seventh Bedson Lecture).

Geologists' Association, at 7.30—(at University College, Gower Street, London, W.C.1).—Annual General Meeting.

P. McIntyre: "Between the Forth and the Tay".

Royal Institution, at 9.—Prof. G. I. Finch: "Electron Diffraction and Surface Structure".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Lecturer in Chemistry, Biology and Physics in the Doncaster Technical College—The Secretary, Education Offices, Doncaster, Yorks. (March 5).

Assistant Curator in the Plymouth Museums and Art Galleries—The Town Clerk, Municipal Buildings, Plymouth (March 9).

Principal Teacher of Mining in the Batley Technical College and the Huddersfield Technical College—The Director of Education, Education Offices, Batley (March 9).

Consulting Physicist at the Royal Northern Hospital, Holloway, London, N.7—The Secretary (March 12)

Assistant Keeper (Industrial Engineering) in the Science Museum, South Kensington, London, S W 7—The Director (March 15).

Regius Professor of Materia Medica in the University of Glasgow—The Private Secretary, Scottish Office, Whitehall, London, S W 1 (March 31)

Sherardian Professor of Botany in the University of Oxford—The Registrar, University Registry, Oxford (April 17).

Lecturer in Geography in University College, Rangoon—The Secretary, Universities Bureau of the British Empire, 88a, Gower Street, London, W.C.1.

The Civil Population and Air Attack

SINCE the issue of the circular to local authorities in Great Britain by the Air Raids Precautions Department in July 1935 urging them to co-operate in schemes of passive defence, public attention has been continuously engaged with this subject, but despite the growing activities of the Department it cannot be said that public opinion is at all happy upon the question. It is increasingly aware of the concern with which informed scientific and technical opinions regards the proposed measures, and the decision of the Government to transfer the shell-filling and other explosives supply departments of Woolwich Arsenal to four centres in the west and north of the country, which are regarded as less vulnerable to air attack, tends to increase rather than to dispel alarm.

While many local authorities have accepted the suggestions of the Government in regard to the organization of air raid precautions and defence, and many large firms are giving the matter active consideration, other local authorities have only accepted the suggestions so far as they relate to the training of fire brigades or police, while a few have refused to co-operate. At first sight, this latter attitude appears somewhat indefensible. The precautions professedly are purely humane in their intention and effect. The five handbooks already issued by the Department outline comprehensive schemes dealing with protection against gas, either in the way of first-aid services, the establishment of the requisite preliminary organization in large commercial or industrial firms and the like, precautions for merchant shipping and methods of decontamination of materials. It is common sense to take every reasonable precaution against so appalling a danger, however remote the probability may be. When the danger is one that can be aggravated so seriously by panic, the support of measures likely to promote order and discipline in the event of attack may reasonably be urged as a public duty.

While this is so, and while it is obvious that effective safety measures cannot be improvised at a moment's notice, a body of opinion, strongly supported by some scientific workers apparently qualified to express views on this subject, has offered important criticism or objection to the proposals on at least four grounds. These objections are summarized in a series of reports which from time to time since August 1935 have been distributed by the National Peace Council, and the present position has been summarized in No. 27 of these reports, by Dr. A. F. W. Hughes, issued in December last.

In the first place, the plans of the Air Raid Precautions Department are regarded as inadequate both in degree and in kind to afford protection for the people from air attack. The main measures of defence advocated are those against gas attack, and the most important criticism is that the danger from gas attack is far less than from attack by high explosive and incendiary bombs, from which there is no protection whatever except properly constructed shelters either underground or with a heavily reinforced roof. The main defence suggested by the Department is that of a gas-proof room with windows and chimney blocked, and to be used for no other purpose. It is obvious that only a minority of the population will be able to set aside a room specially for this purpose. Of the remainder, many live in crowded areas, sometimes in houses insufficiently protected against the weather. Although officials of the Department have publicly admitted the inadequacy of the ordinary house to provide any shelter at all, in October last, Commander Franks, of the Department, was still advising those who could reach their homes to take shelter in them. Moreover, although expert opinion to some extent appears to believe in the possibility of creating bomb-proof buildings as well as gas-proof structures, the need of research in this field has been admitted freely, notably by the Parliamentary Secretary to the Ministry of Health, who stated in July last that an influential committee had been set up to advise on the Air Raid Precautions Handbook "Structure Precautions against Bombs and Gas" which is in preparation. Experiments are still required to establish data in regard to the effect of various types of bombs and gas, and also the resisting power of the miscellaneous materials used in a modern building Even the possibilities of air-conditioning as a defence against gas have as yet scarcely been explored.

These facts in themselves are sufficiently disturbing. The efficiency of the gas mask has also met severe expert criticism. Apart altogether from the psychological difficulty of inducing unskilled workers to wear them—a difficulty with which the industrial chemist is only too familiar—or the attendant discomfort, there is the practical problem of devising a mask effective against any gas which the enemy might possibly use. Without such knowledge, use of a gas mask may be quite ineffective and even engender a false confidence. On the other hand, while that very confidence, whether well founded or not, may help to sustain morale and diminish casualties by avoiding or diminishing panic, the fact should not be overlooked that air raid drill and practice with gas masks may have an effect on the health of the population quite opposite to that intended. The use of the mask may, in fact, engender hysteria and nervous strain that may more than outweigh all the advantage gained against panic.

The second main ground of criticism of the proposals is that they are an essential part of war preparation and have as their avowed object not directly the saving of life or the prevention of suffering, but the strategic necessity of maintaining the public morale and so decreasing the danger in war time of a craving for peace. There is little room for doubt that Government policy in Germany and in Italy is fairly open to this charge, but so far in Great Britain there is little evidence to disentangle this criticism from opposition to the Government defence policy really based on political grounds. At least it can be urged that those who take this view should show that the drawbacks to the gas mask proposals, for example, outweigh its advantages on psychological, apart from technical grounds. There is scarcely any evidence that the whole outlook of the people of Great Britain is other than fundamentally pacific, and those who bring this charge against the Government policy would have a much stronger case if they also attacked that section of the Press which consistently fosters a war mentality and pillories all constructive effort for peace.

None the less, it must be admitted that the third objection to the precautions policy of the Government that, whatever their intention, the precautions cannot fail to create a war mentality which is in itself the most mischievous danger to peace, undoubtedly holds some truth. The nation, however reluctantly, has accepted the Government's defence policy, but is still far from the frame of mind which regards war as inevitable. It would be foolish, however, to ignore the tendency of the whole tenor of recent events in Europe to encourage the mental outlook which will accept conflict as a welcome release from the strain of suspense. It is only too easy to slip insidiously and unconsciously from mere repugnance to war to acquiescence in it on the principle of knowing the worst rather than remain in suspence.

What is equally untoward is the check which the intensification of preparations for war has given to almost all effort designed to deal with the fundamental problem of the elimination of the causes of war. The important discussions which have taken place in the daily Press regarding the future of the mandates system, raw materials, population and the German colonial claims, are only a few examples of directions in which impartial investigation or research is required to provide a satisfactory basis for settlement or to demonstrate the speciousness of merely partisan or propagandist arguments. Despite Sir Samuel Hoare's statement at Geneva in August 1935 regarding an impartial inquiry into raw materials and colonial questions, no steps have apparently been taken to implement the inquiry. The whole spirit of the present defence measures has apparently paralysed such effort. No single action of the Government, however, could do more to disarm the foregoing criticism of its air defence proposals than an emphatic demonstration in some such way of its willingness to make constructive contributions to the elimination of the causes of war by the initiation of these or similar inquiries which might diminish international friction.

Positive action of this type would also offer a weighty reply to the fourth main ground of serious objection to the air raid precautions in which most scientific workers are agreed, that the precautions conceal the truth that there is no possible protection of civilian population from air attack other than the abolition of bombing from the air. Those who realize the limitations of a policy of evacuation or even of the replanning and rebuilding of great cities with an eye to defence against attack by air, as in the Middle Ages they were built against attack under different defence conditions, carry a heavy responsibility if they fail to inform public opinion of those limitations.

Only so can we secure that widespread and intelligent public support for proposals such as the control of national air forces, the organization of an international air force or of effective collective security upon which alone the future safety of civilization appears to depend. Nor can we reasonably doubt that, if the public once realized how limited is the protection available even for those who can afford it, there would be forthcoming that large volume of informed public opinion which, while realizing the inevitability at the present moment of pressing on with measures for national defence, would insist that simultaneously no effort was spared to explore every possibility of international understanding and co-operation in the search for the causes of war itself.

Papuan Pygmies and Art

(1) Walkabout:
a Journey in Lands between the Pacific and Indian Oceans. By Lord Moyne. Pp. xxvi + 366 + 97 plates. (London and Toronto: William Heinemann, Ltd., 1936.) 18*s.* net.

(2) Art and Life in New Guinea
By Dr. Raymond Firth. Pp. 126. (London: The Studio, Ltd.; New York: The Studio Publications, Inc., 1936.) 10*s.* 6*d* net.

(1) THOSE interested in Pacific affairs may recall the unusual and stimulating collection of ethnographical specimens, predominantly from New Guinea, exhibited by Lord Moyne in his London house last summer. His volume, "Walkabout" (Pacific 'pidgin' for travel beyond the tribal territory), records the experiences of the expedition upon which this fine series of objects was collected and also tells us something of the animals brought back to the Zoological Gardens at Regent's Park, London, and of the difficulties of getting them there. But while the collecting of animals and ethnographical specimens was one of the major objects of the expedition, its chief aim seems to have been to study a group of relatively light-skinned pygmies who were said to inhabit the foothills on the north-eastern slopes of the Bismarck Range in Mandated Territory.

The volume sets out in vivid fashion how far the party were successful, and the misfortunes (they came near being something worse) endured in carrying out the programme, in which they succeeded to the extent of bringing home a magnificent series of photographs of pygmies taken by Lady Broughton. These photographs and their discussion constitute the backbone of the book, and the discovery of the Aiome pygmies is no doubt the most important result of the voyage. These pygmies differ entirely from the darker riverain natives, as they do from those of the Aiome foothills, who are still darker than the River people. Twelve males measured by Lord Moyne had an average stature of 54½ in. (extremes 52½ in. and 58 in.), while three women varied from 50½ in. to 53 in. The photographs show that they vary greatly in facial characters, nevertheless certain generalizations can be made:

> "Their upper lips were fleshy, projecting and sometimes everted, with rather pendulous lower lips and receding chins. Brow-ridges were not noticeable. The noses generally were straight and broad, the roots being clearly marked The ends of the nostrils were set square and not diagonally, the bulbs being made to stand out by a bird's quill or as many as four fine sticks cut from the fronds of a sago-palm and worn right through the septum."

Like other New Guinea pygmies, they are skilful gardeners, and it seems impossible to bring their culture into close alliance with any of the Indonesian pygmy groups with which we are acquainted. Who then are these New Guinea pygmies? Are they local groups of 'Papuans' of very low stature, or are they part of a vanishing pygmy negroid stock, whose other representatives are the Aeta of the Philippines and the Semang of Malaya? Where Dr. Haddon, who writes the introduction, leaves us in doubt no one will wish to dogmatize, but the reviewer may record his impression that with a single exception (Plate LIII) the faces of the pygmies here reproduced might equally well be those of natives he knew years ago in the area formerly called British New Guinea, now the Territory of Papua.

So much for the Aiome pygmies, but the book might almost be regarded as a traveller's manual to Pygmydom, for Lord Moyne and his party also visited the Andamanese and the Semang, and again Lady Broughton's camera produced most admirable results.

An appendix by Dr. Cave gives an account of the crania collected, prefaced by a general statement as to the races of mankind. These are correctly given according to current classification, but is it not likely to mislead the layman to tabulate Mediterraneans, Alpines and Nordics as if they were primary divisions of mankind in the same sense as are the Mongoloids, Negroids and Australoids? If Dr. Cave will not have the term Caucasian, surely it should have been indicated that the first three 'races' mentioned belong to a single greater unit (or subspecies) comparable with Negroids and Mongoloids—the White Race.

(2) Dr. Firth's pleasant volume is one of those treats which the proprietors of *The Studio* provide for us from time to time. It consists of about one hundred photographs of objects and typical scenes from New Guinea, the former predominating. Among the representations of village life are a number from the negatives presented by Captain F. R. Barton, a former Governor of British New Guinea, to the Royal Anthropological Institute. To those who, like the present writer, know something of this magnificent series, it will be a treat to see it at last emerging from the disuse into which it had fallen. The life scenes are accompanied by an adequate commentary by Dr. Firth. The reviewer would particularly like to emphasize his agreement with the author with regard to the futility of trying to bring into line surrealism and such objects of native workmanship as are figured in this volume. Geography and European Society

Environment and Nation:
Geographical Factors in the Cultural and Political History of Europe. By Prof. Griffith Taylor Pp. 571. (Toronto: University of Toronto Press; London: Oxford University Press, 1936.) 17*s*. net.

PROF. GRIFFITH TAYLOR holds an honourable place in the society of geographical investigators, and in his research—especially that part concerned with the interrelations of climate and human settlement—he has demonstrated the power of his observant eye. His certainty of touch is most dependable when he is engaged in the study of Australasia, a region with which his name will always be intimately associated. An earlier volume—"Environment and Race"—discussed, in relation to environmental conditions during successive epochs, the evolution of some of the main groups of mankind outside Europe, and it is, therefore, not unexpectedly that we find the present volume devoted to the European communities by whom the idea of nationality was first conceived.

In these days, there are few who claim to understand the intricacies of the political and social fabric of Europe without appreciation of the conditions of physical and human geography which have prevailed during the evolution of the nations. Prof. Taylor attempts this study in historical geography, or geography in retrospect, and finds it—as many other students have done—a particularly difficult subject to interpret. The essential requirement is to know how to employ the records furnished by the historian so as to associate the historical events and trends with the circumstances of geographical environment. On one hand is the temptation towards 'geographical determinism', a conception of history as being determined by geographical laws; on the other, is the danger of indiscriminating use of the historian's materials and the neglect of geographical factors. A very valuable contribution which the historical geographer can make is the reconstruction of the climatic and vegetational environment at successive periods, for it is only by the light of such knowledge that the trends in the prehistory and early history of Europe are made intelligible.

No doubt the author is fully aware of these requirements, but his arguments suffer by being clogged with historical detail. Instances of this are over-abundant and include lengthy reference to ancient Greece and Rome in which there is much military history and singularly little concerning the social and economic geography of the Mediterranean region in past times. The complexity and antiquity of civilization in Europe impose an enormous burden of reading on him who undertakes the study, and it would have been surprising if the author had been able to keep abreast of the literature in so many different fields, including archæology. Recent research in the prehistoric civilizations of Britain and Ireland, in particular, has received little attention. In the case of the smaller country, there is no recognition of its place and significance in the Bronze Age of western Europe.

Some day the genius will arrive who will satisfy our need for an adequate statement of the part that geography has played in the shaping of European society. As a whole, the volume now before us falls short in achievement of the ambition which inspired the author when he began his task, although in one or two chapters, particularly one devoted to Russia, there are instances of satisfactory fulfilment. Throughout, the author seems to be reminding himself that nationality is a product of 'place' rather than of 'race', but repeatedly he wanders into historical and ethnological descriptions, leaving the geographical factors unexplained and sometimes ignored. Least satisfactory are the chapters devoted to the nation-states of France and Britain in which, by unnecessarily lengthy reference to invasions and annexations, he distracts attention from the coalescence or welding together of regions, each with its own 'personality', out of which statehood and nationality evolved. It is a matter for notice, though not indicated by the author, that in each country mentioned above the establishment of the State preceded the development of national consciousness, whilst in the case of Germany the idea of nationality was widespread long before its political expression was fully achieved.

In matters of detail there is the opportunity for much careful revision, in readiness for a second edition, and it is essential that an adequate bibliography should be added. W. F.

World Power Statistics

Statistical Year-Book of the World Power Conference

No. 1: 1933 and 1934. Edited, with an Introduction and Explanatory Text, by Frederick Brown. Pp. 111. (London: World Power Conference, 1936.) 20*s.* net.

COMPILATION of a volume containing comparable statistics of resources, production, stocks, imports and consumption of power and power sources of all countries of the world would appear to be a superhuman task, bearing in mind the present lack of international classification of power types and widely different methods of collecting and recording data employed by countries and public bodies throughout the world. The International Executive Council of the World Power Conference has for a number of years past sponsored the systematic compilation of inventories of power resources by national committees and by Government and other organizations, and has so far as possible ensured their return in comparable form by the circulation of definitions of each power type. This action on the part of the Council has now made possible the issue of a year-book relative to the years 1933 and 1934.

It is admitted in the introduction that the volume is capable of improvement in subsequent editions, and that the work of collection of statistics has by no means reached finality. The criticism might also be levied that the wealth of annotation, sub-division and definition (admittedly appended solely in the interest of strict accuracy) is cumbersome to the reader who strives in his own mind to form a concise idea of the approximate world resources of a given fuel, but who is continually thwarted by observations such as that made in the case of coal. . . . "The largest areas for which no estimates are presented are in Africa, Asia, and Central and South America; it is known that coal reserves exist in many countries in these areas but, . . . exploitation of these resources has hardly begun, and their magnitude has not been even approximately estimated". Nevertheless, in spite of manifest drawbacks, the book probably embodies the most comprehensive collection of power studies as yet published.

Power types are divided into five major classes —solid fuels, including coals, brown coal, lignite, peat and wood; liquid fuels, sub-divided into petroleum, benzoles, alcohols; gaseous fuels (natural gas), and water-power and electricity. In each case a note is given of the scope and meaning of the statistics. This is followed by a table of Continental and world totals, and finally by standard definitions applicable to the particular section. The tables themselves give resources of the power type, listed under continents and countries, and annual statistics of production, imports, exports and consumption for the years 1933 and 1934 wherever available.

It is to be hoped that this volume will be followed by other editions which will justify more fully the tremendous amount of time and energy put forward by its promoters. It would also be desirable, if possible, to reduce the price of later editions, as twenty shillings is excessive for a year-book of this character.

Micro- and Macro-Analysis

(1) Semi-Micro Qualitative Analysis

By Prof. Carl J. Engelder, Tobias H. Dunkelberger and Dr. William J. Schiller. Pp. x+265. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 13*s* 6*d*. net.

(2) Semimicro-Methods for the Elementary Analysis of Organic Compounds

By Prof. Dr. Eduard Sucharda and Boguslaw Bobranski. Authorised translation by Dr. George W Ferguson Pp. vii+52. (London: A. Gallenkamp and Co., Ltd., 1936.) 6*s*. net.

(3) A Textbook of Elementary Quantitative Analysis

By Prof. Carl J. Engelder. Second edition. Pp. xiv+270. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 13*s*. 6*d*. net.

(1) FOR many years, analytical chemistry had maintained a fairly static state; dependable methods of detecting and estimating the more commonly used elements had been worked out, and these were adhered to in a more or less rigid manner. During the past two decades, however, there has been a remarkable revival of interest, new methods have been adopted and a nearer approach made to the ultimate ideal of one specific procedure for each cation or anion. This movement has been due partly to the use in industry of a larger number of the chemical elements, especially the so-called rarer elements, partly to the discovery of increasingly sensitive reagents and partly to the desire of the analyst to know more and more about less and less. The two latter causes have conspired to give birth to microchemistry, a subject which has advanced so rapidly that it will undoubtedly play a large part in future schemes of analysis. For that reason, the authors of the work under review have deemed it wise that students should have practical acquaintance with some of the technique of micro-analysis. They have therefore developed a scheme whereby drop-reaction methods are applied to the ordinary system of qualitative analysis, and for which 1–2 c.c. of solution containing some 20 mgm. of material suffices for the usual group separations and confirmatory tests.

The book is divided into four sections, the first of which deals with the theoretical principles underlying qualitative analysis. This is written in an interesting manner and covers a remarkably wide field. In the second part there is set forth the reactions of the cations appearing in the various analytical groups, and included here are many 'spot' tests employing organic reagents. A similar treatment is then applied to the commoner anions, while the last section deals with the systematic analysis of mixtures.

The work provides an excellent introduction to drop-systems of detection and will be found useful both to students and to the more advanced worker. Its value is further enhanced by numerous references to the literature of qualitative micro-analysis.

(2) Micro-methods of organic analysis are now well established and are gradually displacing the macro systems. Nevertheless, they suffer from one disadvantage in that they require a special balance which, in turn, needs a suitable place for its erection. Many workers have therefore sought to develop semi-micro or centigram methods for which an ordinary balance accurate to 0·1 milligram can be used. In this book, Prof. Sucharda and Dr. Bobranski outline such a scheme for the estimation of carbon and hydrogen, nitrogen and the halogens, using 20–30 mgm. of material. In addition, there is also described a semi-micro ebullioscopic determination of molecular weights.

The technique of these elementary analyses is based almost entirely on that of Pregl, although in the carbon-hydrogen determination there is one notable refinement. In order to ensure a constant excess of oxygen during combustion, use is made of an automatic regulator whereby the size of the flame causing the vaporization of the material is controlled by the pressure inside the combustion tube. Consequently there is no need to count bubbles or read a manometer; indeed the presence of the analyst is superfluous during this part of the operation.

Halogen compounds are burnt in oxygen with the aid of platinum as catalyst, but, in the case of chlorine or bromine, the halogen is absorbed in heated barium carbonate. Iodine is taken up in sodium sulphite, but, as the halides formed in each case are titrated argentiometrically, excess of sulphite must be removed as the barium salt.

This monograph has been excellently translated from the original German version, and, although small, it contains adequate details of the procedures employed. These methods should provide a good opportunity for acquiring the technique of micro-organic analysis without incurring the expense of a micro-balance.

(3) Most text-books of elementary quantitative analysis are nothing more than a heterogeneous collection of estimations which the student is expected to carry out, often without knowing the reasons underlying the various processes. The present book, however, does not suffer from this defect, for theory and practice are blended most judiciously.

The manual opens with a section on such fundamental principles as the law of mass action, the use of the balance and the errors and precision of quantitative methods. It then treats of volumetric analysis, this section covering half the book and containing an excellent chapter on the theory of neutralization and the use and selection of indicators. The gravimetric part of the work deals with the usual common precipitations, while there is also a short section on electro-analysis. The text includes numerous problems, and the student who solves them all and carries out the various estimations will have received a sound grounding in quantitative analysis.

The value of the book is best illustrated by the fact that a second edition is called for so soon; this differs but little from the original one and that mainly in the arrangement of the text.

Training of Engineers

Advanced Laboratory Practice in Electricity and Magnetism

By Dr. E. M. Terry. Revised by Prof. H. B. Wahlin. Third edition. Pp. xiv+318. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 18*s*.

THE layout of this book is so curious that a few words on the purpose of laboratory work for budding engineers must precede our criticism.

Assuming that the purpose of an academic and educational course of training is to make a student think accurately and consistently in a given field of activity, with some overflow of these faculties for living socially with other men, it appears that the time considered adequate for acquiring these attainments is too short to permit contacts with more than a small section of the chosen field. It may or may not be desirable to use little beyond laboratory work in such training, particularly for electrical engineers, but since in laboratory work economy severely restricts the materials and apparatus available for student use, and he cannot spend all his time wandering around works and other commercial examples of modern technique, it is clear that the function of the laboratory must be restricted to illustrate practically but effectively a selection of useful fundamental principles which inculcate faith in the wider field described in lectures and consolidated in exercises and design work. It is clearly the utilization of the most effective means within a given set of conditions, remembering that a student is most teachable when studying fundamental ideas illustrated by applications in which he is interested.

Returning to the book under notice, we find a large number of elementary experiments which are more suited to second year students than third year students as stated, assuming that they take final examinations at the end of the third year, which is not stated. We also find a considerable number of advanced electronic experiments which are more suited to an advanced physics course than an engineering course. We gather that the course is for communication or high-frequency engineers, but experience shows that these require a fair knowledge of the so-called power side, and there is none of this.

While the radio section is good, there is insufficient body in the middle grade of experiment, and the reader must conclude that a student may be left with a superficial idea of the practice in modern electrical communication. For example, the most used bridges in this field, the series-resonant bridge and the capacity and conductance bridge, and the most useful method of impedance measurement, up to very high frequencies, the hybrid-coil set, are not mentioned. In taking this course one would like to feel that every student has taken a certain number of the most important fundamental experiments and then devoted his time to something which is more extended, but selected so as to make a special appeal to him; but this is not suggested. Perhaps the choice is left to the able demonstrators who are always required for an advanced course. L. E. C. H.

Fondamenti della meccanica atomica

Per Enrico Persico. (Trattato generale di fisica a cura del Consiglio Nazionale delle Ricerche.) Pp. iii+510. (Bologna: Nicola Zanichelli, 1936.) 80 lire.

IN the development of a comparatively new subject, such as quantum mechanics, advances are made by a few brilliant pioneers, each working on his own lines. At this stage it is very difficult for a student of average attainments to grasp the subject as a whole. We owe a deep debt of gratitude to Dr. Persico for undertaking the useful task of presenting, in a single volume of reasonable size, a unified account of all aspects of the subject.

The book is divided into three parts. The first, which is very easy reading, describes the fundamental experimental results, and the simple Bohr theory of the hydrogen atom. The second part opens with a mathematical discussion of orthogonal functions, and then develops Schrödinger's wave equation. The applications include the harmonic oscillator, the hydrogen atom, and other problems of a single particle. A good example of the author's skill in correlating his material is the way in which an approximate treatment of the wave equation leads on to the Sommerfeld conditions of the older quantum theory and their application to elliptic orbits. This order violates the historical development, but it makes things much easier for the student.

The third part is the most difficult. It opens with a discussion of functional and Hilbertian space, linear operators and matrices. It then explains Dirac's ideas of observables. After further developments of the matrix method, we pass to the theory of perturbations. Another chapter deals with relativity, spin, and Dirac's linear wave equation, and the final chapter with Pauli's principle. The book concludes with a bibliography and an index.

There are a few places where more advanced students would desire a fuller treatment, but the only serious defect of the book is that it is in Italian. Will some publisher consider the possibility of an English translation? H. T. H. P.

Croydon Natural History and Scientific Society

Regional Survey Atlas of Croydon and District. Pp. 19+12 plates+Locator template. (Croydon: Roffey and Clark, Ltd.; London: Thomas Murby and Co., 1936.) 12*s*. 6*d*.

FOR several decades, the Croydon and District Natural History Society has been to the fore in advocating the importance of regional survey. In the view of Mr. C. C. Fagg, such a survey need never be complete but can continue to record facts on outline base maps and the maps listed and classified according to a scheme which, in its decimal system, recalls the Dewey system for books. A start has been made with the publication of some of the material collected; a substantial binder has been issued together with the classification scheme, specimens of the base maps (one covering a limited area on the one-inch scale, the other a larger area on the half-inch scale, both being reproductions of the Ordnance Survey maps in grey), a geological map and an outline on transparent paper, map of rivers, rainfall map and map of Roman roads. There are valuable notes on each map and a half-tone reproduction of Say's "Plan of Croydon" (1785).

This is a promising start, though regrets must be felt that so much of this material is available in maps of the Geological and Ordnance Surveys. Issues of new maps, to be distributed at a price varying with the cost, are promised from time to time. A glance at the classification scheme suggests that difficulties may arise—thus 82 includes land (tenure, ownership, utilization, value)—and that modifications may be needed. L. D. S.

Easy Methods for the Construction of Magic Squares

By Major J. C. Burnett. Pp. 77. (London: Rider and Co., 1936.) 2*s*. 6*d*. net.

IT is rather difficult to describe this little book. It is in no sense a systematic discussion of the construction of magic squares. Rather it consists of a series of examples to show how, by the method of 'complementary differences', a variety of problems relating to these squares may be solved; and it attempts no general theoretical discussion. Starting with the construction of an associated magic square of the fifth order, that is, one in which the sum of two numbers placed symmetrically with regard to the centre of the square is constant, the author proceeds to discuss bordered squares, magic rectangles and the like, in each case by particular examples. The language of the book is described as non-technical. This is a fair description, in the sense that the book lacks the precision of statement usually expected in mathematical works. For example, the use of the verb "to be" in the definition "Reversions are when the Squares are merely turned round . . ." is surely an archaism; and there are several other places where, though the author's intentions are clear, his explanations do not conform to modern grammatical standards. J. A. TODD.

An Elementary Chemistry

By A. H. B. Bishop and G. H. Locket. Pp 398. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 4*s*. 6*d*.

THIS is a text-book written by teachers who have aimed at making the subject interesting and also are aware of the usual difficulties encountered by young pupils. It includes details of a number of instructive experiments which can be performed in the classroom or laboratory, and the many little hints given in these descriptions show that the authors appreciate the conditions under which the experiments will be successful. All teachers will be well advised to have a copy of this book, if for no other reason than the help they are likely to obtain from the descriptions of the experiments. Emphasis is laid on everyday aspects of chemistry and there are some excellent plates of industrial apparatus, etc. The text is clear and well arranged, and there is a good selection of examination questions. The treatment throughout is from the modern point of view and the arrangement of topics will be found to work well in actual teaching.

The Origin of Fahrenheit's Thermometric Scale

By Dr. J. Newton Friend

THE scientific world has recently paid tribute to the bicentenary of the death of the renowned German instrument maker, Daniel Gabriel Fahrenheit[1], who was born in Danzig in 1686 and died at The Hague on September 16, 1736.

Ever since the general acceptance of his thermometric scale, there has been much discussion as to why Fahrenheit chose such an apparently inconvenient numerical relationship as 32° and 212° for the freezing and boiling points of water respectively. Published opinions have differed widely. Martine, a contemporary of Fahrenheit, believed that, having once fixed his zero, Fahrenheit chose his scale in a purely haphazard manner, as explained later on. On the other hand, an entirely different view is put forward in Chambers' "Encyclopædia"[2], where we read :

> "Fahrenheit took as his zero the lowest temperature then obtainable (from a mixture of salt and ice) and called the temperature of the human body 8°. Each degree was subdivided into 12 parts ; and subsequently these twelfths were taken as degrees. This made the temperature of the body 96° ; and it was found that the freezing point of water was 32°."

These illustrations will suffice.

Fresh light has been thrown on the problem by the recent discovery in the Military Medical Academy at Leningrad of certain letters sent by Fahrenheit to Boerhaave during the period 1718–29. These letters were written in Dutch at Amsterdam, and a literal translation of one of them into German, dated April 17, 1729, is given by the Cohens (*loc. cit.*)[1], which enables us to settle the question fairly satisfactorily.

It may be said at once that Fahrenheit did not choose 32° and 212° for the freezing and boiling points of water ; they were mere incidents on his scale, which was chosen independently of them and was based upon two fixed points, namely, a zero obtained by immersing his thermometer in a mixture of ice and sal ammoniac, and an upper point at blood heat, which Fahrenheit took as 96°.

The purpose of the present article is to attempt to explain :

(i) Why the above mentioned temperatures were chosen as bases of Fahrenheit's scale in preference to the freezing and boiling points of water ; and

(ii) why the upper fixed point was designated as 96°.

In order to answer these questions a knowledge of the early history of thermometry is necessary. A brief résumé is all that can be attempted in these columns.

The term thermometer appears to have been first used by Father Leurechon (1591–1670), a French Jesuit, in his work entitled "Récréation Mathematique", dated 1624. The credit of inventing thermometers with a liquid indicator (actually spirits of wine) hermetically sealed in a glass tube is usually given to Ferdinand II (1610–70), about 1650 ; he was Grand Duke of Tuscany, a liberal patron of science and founder of the Accademia del Cimento at Florence. Prior to these, air thermoscopes or baro-thermoscopes had been used for comparing relative changes in temperature. These were (probably) invented either by Santorio (1561–1656), professor of medicine at Padua and colleague of Galileo, or by Galileo (1564–1642) himself, about 1592. The utility of these thermoscopes was severely limited by their susceptibility to changes in atmospheric pressure. As no standard temperature scale was recognized, it was at first impossible, even with the Ferdinand or Florentine thermometers, to collate the results of different investigators. This very serious defect was soon realized, and steps were taken to find a remedy.

THE LIQUID INDICATOR

It was regarded by some as sufficient to select a single fixed point at an easily reproducible temperature and regard that as the zero or null point. Other temperatures were measured by noting the percentage or other fractional change in volume of the liquid indicator once the null point had been marked off on the thermometer.

Clearly the nature of the liquid medium was a matter of supreme importance, for, if the results of different investigators were to be collated, either the same liquid indicator must be used by all, or one possessed of an identical coefficient of expansion. Halley (1656–1742) directed attention to this, having observed that all liquids do not expand by similar amounts with rise of temperature[3]. Further, the exact volume of the liquid in the bulb of the thermometer must be known in order that the fractional volume change may be calculated and the temperature evaluated.

Boyle (1627–91) proposed *water*. He recommended taking a vessel of water and noting the volume of the liquid at the boiling point. On cooling to a lower temperature, the latter could be registered in terms of the contraction of the water as parts per 10,000 of the boiling volume. But this suggestion did not find favour despite the abundance of water and the ease with which it could be obtained in a pure condition. Water was regarded as an unsuitable liquid indicator, for not only was its coefficient of expansion small as Halley pointed out[4], but also its freezing point was too high for many meteorological purposes, and it was for this kind of work that thermometers were largely required. Its irregularity of expansion with rise of temperature did not much matter; it would scarcely be noticed, for the general experimental error was high.

Newton[5] (1642–1727) used *linseed oil*, noting its volume at the temperature of melting ice and, like Boyle, expressing its change in volume as parts per 10,000. Martine[6] quaintly refers to his experiments as follows:

> "Sir Isaac Newton thought the settling [of] the degrees of heat and cold well worth his notice; and as he carried everything he meddled [*sic*] with beyond what anybody had done before him, and generally with a greater than ordinary exactness and precision, so he laid down a method of adjusting thermometers in a more definite way than had been done hitherto."

But although linseed oil has a low freezing point and a large range of liquidity, its use in thermometry did not become general, despite Newton's fame as an investigator and the fact that the oil could be used at temperatures far above the boiling point of water. This was probably due to the fact, to which Martine directs attention, that, in consequence of its high viscosity, the oil drains very slowly, particularly at the lower temperatures, down the sides of the tube bearing the scale; the thermometer thus takes a long time to adjust itself to new conditions.

Ferdinand (*vide supra*) ordered his thermometers to be made with *spirit*; Boyle was quick to appreciate their merits and introduced them into England. Referring to them, Martine says they "came immediately to be of universal use among the virtuosi in all the several countries, wherever polite learning and philosophy were cultivated". The scale divisions were approximately one fiftieth of the volume of the bulb. Sagredo[7] used 360 divisions, like the graduation of a circle; hence the term degree, as applied to temperature.

The low freezing point and viscosity of spirit were excellent features, but a really serious difficulty lay in the fact that the coefficient of expansion was found to vary greatly with the quantity of admixed water. Réaumur, as we shall presently see, made use of this property when devising his scale some years later.

Fahrenheit favoured the use of *mercury* as well as of spirit; indeed he was the first to bring the mercurial thermometer into general use.

Martine, as has already been mentioned, believed that Fahrenheit chose his scale in a purely haphazard manner, using mercury as indicator. He records that Fahrenheit took a volume of mercury measuring 11,124 parts when cooled in ice and sal ammoniac; 11,156 parts in melting ice—a rise of 32 parts or degrees; and 11,336 parts in boiling water—a rise of 212 degrees *in toto*; whence his scale. Martine[8] then comments on the extremely arbitrary character of the scale, adding, "I confess there might have been a more convenient one fixed upon at first". We agree.

Martine quotes as his authority Hermann Boerhaave (1686–1738), professor of medicine and chemistry at Leyden, from whose work entitled "Elementa Chemiae"[9] the above accounts were taken. There is evidently a misunderstanding here for, in view of Fahrenheit's letter to Boerhaave discussed below, it does not seem at all possible that this could have been the origin of his scale. It is more probable that, if Fahrenheit did carry out this experiment, the particular volume of mercury was deliberately chosen because it would give the necessary expansion to fit in with his own already existing scale.

SELECTION OF FIXED POINTS

Some investigators, Martine included, advocated the use of a thermometric scale based upon two fixed points instead of one only. Any suitable liquid could then be used as indicator, and the necessity no longer existed for determining with great accuracy the volume of the bulb of the thermometer. All that one had to do, and this was comparatively easy, was to note the levels at the two fixed points and divide the distance between them into as many parts or degrees as was held convenient. Newton and Ole Rœmer (see below) appear to have been the first to devise such scales prior to 1703.

Numerous suggestions were made for the selection of fixed points. Boyle[10] recommended the freezing point of oil of aniseed (17°–20° C.) as zero, because it was not necessary to wait for frosty weather before it solidified. Halley thought a cave might be selected where summer and winter temperatures are alike; one such cave was known to Boyle, and Mariotte[11] claimed that the cave under the Royal Observatory at Paris was also isothermal. Newton chose the freezing point of water as his zero.

Boyle[12] was aware that an intense cold could be produced by mixing ice and salt. Ole Rœmer (1644–1710), the Danish astronomer famous for his measurement of the velocity of light from a study of the movements of Jupiter's satellites, used this mixture or a similar one (ice and sal ammoniac, see later) in obtaining his zero, which was regarded as the lowest temperature then attainable in the laboratory. Some years later, Fahrenheit adopted the same zero, and has hitherto, but incorrectly, been regarded as its originator.

Boyle's suggestion is ruled out because oil of aniseed is a natural product and as such does not possess a fixed composition; its melting point is thus liable to vary. For geographical reasons, Halley's idea is impracticable, as a particular cave could not be visited by everyone desirous of checking his thermometer.

Newton's idea appears to be the simplest and most convenient. Why, then, was it not generally adopted?

The reason seems to be that scientific investigators believed the freezing point of water was not constant, but varied with the latitude, Halley and others asserting that, the farther north we go, the more cold is required to freeze the water—to use the then current phraseology.

Martine[13] refers to this, and appears to have been the first to show that such is not the case. He rightly attributes the observed differences in the freezing point of water either to inaccurate observation or to the use of imperfect thermometers. He says that he marked the mercury level on a thermometer at Edinburgh, when immersed in snow and water, whilst a friend did the same with another thermometer in London. They then exchanged instruments and tested them, finding them to agree perfectly. Evidently the difference in latitude between the two cities had not affected the freezing point. Later experiments as far south as Paris and Dijon yielded similar results.

For his upper fixed point Newton chose blood heat; this was regarded as absolutely constant for a healthy person. He designated this temperature as 12°, probably because the number is easily subdivided and remembered, as there are 12 inches to the foot; the decimal system was not in general use in scientific work. As we have seen, his 0° was obtained in melting ice.

In "Adversaria", which was printed in 1910, the MS. having been mislaid for about 200 years[14], Rœmer gives an account of the construction by him of a standard thermometer in 1702–3. The scale of this thermometer was based upon *two* fixed points, the upper one being the boiling point of water, which he designated as 60. In checking his thermometers he used this temperature and, for convenience, possibly also for greater accuracy, the melting point of snow or crushed ice. This latter temperature, however, was not his zero, but fell on his scale at 7½ degrees. According to Fahrenheit, Rœmer also used blood heat in checking his thermometers, presumably when intended for meteorological use, as it was not necessary for these to be graduated to so high a temperature as the boiling point of water. In his letter to Boerhaave dated 1729, to which reference has already been made, Fahrenheit states that he met Rœmer in Copenhagen in 1708 and saw him testing some thermometers by placing them first in ice and water and afterwards into water at blood heat. The scales on the instruments were divided into 22½ parts, beginning at 0. When placed in iced water the reading was 7½; at blood heat, 22½. How the zero was obtained is not definitely stated either in "Adversaria" or in Fahrenheit's letter, but simple calculation shows that it corresponds roughly to the temperature of a mixture of salt and ice. This is supported by the fact that Fahrenheit then goes on to say that he himself later adopted the same temperature scale but with this small difference, namely, that he divided each of Rœmer's divisions into quarters, presumably for ease of reading. Evidently, therefore, Fahrenheit adopted the same zero, and this, he had stated[15] in 1724, was obtained "by the commixture of ice, water and sal ammoniac, or even sea salt". From the fact that he quotes sal ammoniac and sea salt as alternatives we gather that Fahrenheit supposed they yielded the same temperature with ice. We now know that their cryohydric points are − 15° C. (or + 5° F.) and − 22° C. (or − 8° F.) respectively. Nevertheless, Fahrenheit did realize that there was a difficulty in reaching the true zero, for he naively remarks that "if into this mixture the thermometer be put, it descends to 0. This experiment succeeds better in winter than in summer"!

We wonder what the toleration of his thermometers would amount to. Martine mentions[16] that he had occasion to test some Dutch mercurial thermometers, but found them in error by one or two degrees.

Halley[17] recommended, for the upper fixed point, the boiling point of spirit of wine,

> "only it must be observed, that the spirit of wine used to this purpose, be highly Rectified or Dephlegmed for otherwise the differing goodness of the spirit will occasion it to boil sooner or later, and thereby pervert the designed exactness".

Several workers recommended the boiling point of water as the upper fixed point, using the freezing point as zero. Martine favoured this idea and it was acted upon by René de Réaumur (1683–1757), the French scientist, who found that the best spirits of wine of his day expanded by 87½ parts per 1,000 when warmed from melting ice to boiling water[18]. Equal parts of his spirit and water gave an expansion of 67½. He therefore for simplicity chose such a mixture as expanded by

80 parts. Hence the Réaumur scale runs from 0° to 80° between those two temperatures. The choice was not accidental, as we frequently read, but by design.

In 1736 Celsius (1701–44), in contrast to previous workers, favoured the decimal system and divided the same interval into 100, thus giving us the Centigrade thermometer. At first he denoted the freezing point by 100 and the boiling point by 0, but this scale was afterwards inverted.

It was known to Martine[19], to Fahrenheit and possibly also to Boyle that the boiling point of water varies with the pressure. This, however, was not regarded as a serious drawback to its use as a fixed point because, as Martine states,

> "in ordinary changes of the weather, the difference is not very great. And farther, we may avoid all errors that might arise from anything of that sort, if we make our observations on the heat of boiling water, and adjust this term of heat at a middle state of the atmosphere in places near the level of the sea, when the quicksilver in the barometer stands at about 30 inches, or a very little under it. And the same caution will be necessary in judging the heat of boiling spirit of wine, or of the boiling heat of any other liquid."

The Fahrenheit Scale

We have seen that Fahrenheit, on his own admission, based his scale on that of Rœmer. This confirms the conclusion to which Kirstine Meyer[14] had already come in 1910, after examining the scales on some early Fahrenheit thermometers and collating various statements in contemporary literature.

If we ask what were the features of Rœmer's scale that attracted him and led him to reject the freezing and boiling points of water as his zero and upper fixed point respectively, the answer is undoubtedly to be found in the fact that the majority of his thermometers were intended for meteorological purposes.

The freezing point of water is relatively high, and if taken as zero involves the repeated use of negative values for winter temperatures. By using the then lowest attainable temperature as zero—the "absolute zero" of those days—all the meteorological readings would be positive. Fahrenheit probably objected to the conception of a negative temperature, just as we do to-day in regard to our own absolute scale.

As regards the upper fixed point, the temperature of boiling water was rejected as being unnecessarily high for meteorological purposes and inconveniently high for spirit thermometers. Fahrenheit states[20] that he was accustomed to use the same fixed points for all his instruments, whether spirit or mercury, when intended for meteorological purposes.

Fahrenheit went on to say, in his letter to Boerhaave, that in 1717 he felt Rœmer's scale with its fractions to be both inconvenient and inelegant; so instead of 22½° divided into quarters, that is, 90, he decided to take 96° as blood heat. Retaining the same zero, the melting point of ice became 32°, instead of 7½° divided into quarters, or 30. This scale he continued to use and was using at the time the letter was written (that is, in 1729); he added that he had been confirmed in his choice because he found it to agree, by pure coincidence, with the scale marked on the thermometer hanging in the Paris Observatory.

Fahrenheit gave no reason for regarding the number 96 as more convenient than 90. Probably it was due to the fact that 96 is divisible not merely by 3 but also by multiples of 2 and hence by 12. The decimal system was not then in general use in scientific work, otherwise Fahrenheit would no doubt have fixed blood heat at 100°. In that case the freezing and boiling points of water would have been represented by numbers even more awkward and disconnected, namely, 33·3° and 221° respectively. So let us be thankful.

Although we retain a Fahrenheit scale to-day, it is not quite the same as that which Fahrenheit used. The lower and upper fixed points adopted are those deliberately rejected by Fahrenheit, ice being taken to melt at 32° and water to boil under standard conditions at 212°.

In conclusion, I gladly express my indebtedness to Mr. H. W. Robinson, librarian of the Royal Society, to the staff of the Birmingham Public Library and last, but by no means least, to my friend Mr. F. W. Clifford, librarian of the Chemical Society, for their kind assistance whilst I have been examining the early documents referred to in this article.

The Ancestry of Insects*

By Dr. A. D. Imms, F.R.S.

THE insects are unknown in their original or primitive manifestations and consequently their ancestry is wrapped in obscurity. The subject can only be approached by the co-ordination of whatever evidence may be gleaned from three principal courts of appeal—comparative morphology, embryology and palæontology. Of these, palæontology has, so far, remained almost like a closed book: no annectant forms bearing directly upon the problem have been disclosed in the strata of any geological period. Without this necessary record of the past, the links in the evolutionary chain are deductions based mainly upon morphology and development. For a considerable time past, the two most plausible theories of insect descent have been those which involved either the Crustacea or Symphyla as ancestors. The Crustacean theory, which is based no external structure, is losing ground, while that involving the Symphyla has remained in much the same status that it acquired in the days of Packard.

The most important evidence bearing upon insect ancestry that has come to hand during the last thirty years or more was Silvestri's[1] discovery, in 1903, of the remarkable thysanuran *Anajapyx*; since that date, no revelation of comparable significance has been made. While this discovery added weight to the symphylan theory, Packard's conclusion of 1898[2] still holds good to-day. This writer stated that *Scolopendrella* is the only extant arthropod, which, with the sole exception of being progoneate, fulfils the conditions required of an ancestor of the Thysanura and, through them, of the winged insects. In 1930, Tillyard[3] brought forward a theory which claimed that the Insecta were derived from remote hypothetical nauplioid ancestors ("Protaptera"): they arose separately from the Symphyla and other Myriapoda which, he maintained, had a similar origin. The symphylan theory was rejected by this author owing to the old crux of the segmental location of the gonopore.

The contention of the present communication is that the symphylan theory is substantiated by a larger body of evidence than any other explanation of insect descent. In considering this theory, it needs to be stressed that it is generally accepted to-day that among the Thysanura are found the most generalized of all insects: *Lepisma* and its allies are the forerunners of the Pterygota, while *Anajapyx* and *Campodea* are more nearly related to the ancestral insects. The old phylogenetic importance of *Campodea* has now been largely eclipsed by *Anajapyx* with its greater display of symphylan characters. Since *Anajapyx* provides an essential link in the present theory, these characters need to be recounted. They include simple multi-articulate antennæ: styli and eversible sacs on most of the abdominal segments: cerci bearing the orifices of large posterior glands: mouth-parts built on an essentially similar plan: an identical leg-segmentation with single-jointed tarsi: a simple digestive canal with homologous salivary glands and the same fundamental type of excretory organs. A second link in the chain is provided by embryology. The lower insects pass through a developmental phase revealing fourteen postcephalic segments, each bearing limb rudiments. This phase can only be interpreted as a relic of a former polypodous condition. On turning to the Symphyla, it will be noted that they reveal, in their adult structure, close resemblance in metamerism as evidenced by the appendages: namely, twelve pairs of legs, the thirteenth pair transformed into sensory processes and the fourteenth pair, as in insects, represented by cerci. Thus it seems very possible that the Insecta recapitulate what may be regarded as a symphylan stage in their development.

In the derivation of the Insecta from symphylan ancestors, it would appear that three main evolutionary changes were involved. (1) The development of a segmental tracheal system. (2) Concentration of the locomotory function in the first three postcephalic segments, with the consequent reduction of the appendages of the remaining segments (other than cerci) to a vestigial condition. (3) The development of posterior gonoducts opening between the tenth and eleventh postcephalic segments, together with the atrophy of the original ducts. (1) and (2) require little comment since they are evidenced in the development of the lower insects and in the adult structure of the Thysanura. In connexion with (3), it is noteworthy that a shifting backwards of the genital apertures during development is a common feature among many orders of insects. Furthermore, new (or secondary) genital passages and orifices have been acquired among Lepidoptera, Strepsiptera and in the Hemipterous family Cimicidæ. The postulation of a change from a progoneate to an opisthogoneate condition refers, therefore, to the evolution of a class wherein diverse modifications of the genital conduits are a prominent feature. The Insecta are peculiar in that the egg-follicles are disposed in a linear series forming ovarioles, while at the apex of each ovariole is an end-chamber (or germarium) containing the undifferentiated germ cells. In other arthropods no such arrangement into ovarioles prevails and the germarium is located parietally. It will be evident that structural modifications of the gonads must have been involved during the evolution of the Insecta, and, it is claimed, that these changes occurred in association with the development of posterior gonoducts.

---

* The present article is an abbreviation of one bearing the same title (*Trans. Soc. Brit. Entom.*, 1, 1936) the main features of which formed the subject of a presidential address given to the Society for British Entomology, at a congress held in Cambridge on June 26-29, 1936.

So far, the Protura and Collembola have been omitted from discussion: they are side developments off the main line of insect descent. The Protura show a predominance of hexapod features, suggesting that the early evolution of this group was with the rest of the Insecta. Afterwards they diverged as a specialized side branch but retained the primitive trait of anamorphosis. The Collembola display both myriapodan and insectan characters. Owing, possibly, to the paucity of yolk, which has induced holoblastic segmentation, development became arrested and only nine trunk segments formed. In the absence of ovarioles and retention of the parietal germarium, together with the general simplicity of the gonads, the Collembola betray close resemblances to the Symphyla. The possibility that traces of a former progoneate ancestry are revealed in Collembola, as mentioned by Claypole[4], needs further investigation; evidence of such ancestry also requires exploration among other Apterygota.

Re-examination of the symphylan theory seems, therefore, to establish it as the only adequate explanation of insect descent. In view of the many fundamental similarities between the Symphyla and Thysanura, it is claimed that these two groups arose from a common stock, not very different from living forms of Symphyla. Theories involving separate origins for the two groups in question, on the grounds of disparity in the segmental locations of the gonopores, have to fall back upon the improbable hypothesis of convergence to account for their community of structure. If the propositions now advanced serve to focus attention upon aspects of the problem hitherto neglected, they will have fulfilled their purpose.

The Recent Floods in the United States*

By Dr. C. E. P. Brooks

THE Mississippi and its tributaries together drain about half the area of the United States. The Mississippi itself runs through the centre of the country, the Missouri rises in the Rocky Mountains and the Ohio in the Allegheny Mountains. The upper courses of the Mississippi and Missouri lie in relatively dry regions, where moreover the winter precipitation is mainly in the form of snow. The Ohio, on the other hand, runs through a region of comparatively heavy rainfall, and is much more liable to flooding.

During the last few months of 1936, the rainfall in the valley of the Ohio and the Mississippi above Memphis had been abnormally heavy, the total for the months September–December being nearly one and a half times the normal. Thus at the beginning of January, the ground was waterlogged and there was already minor flooding in some of the tributaries of the Ohio. In January a type of pressure distribution developed which was very favourable to prolonged heavy rain (Fig. 1). Pressure was high off the east coast of the United States, and decreased steadily westwards. This was associated with a current of warm moist air blowing from the Caribbean Sea and the Gulf of Mexico across the eastern half of the United States. Above this warm and very moist south-easterly wind was an upper current from the west, which was relatively cool. The air was therefore highly unstable. Farther north, over the Great Lakes and southern Canada, pressure decreased northward, and the westerly current descended to ground-level. The encounter of the warm moist south-east wind with this great barrier of colder air from the west gave all the conditions necessary for heavy and prolonged rain, which was localized by a series of depressions travelling from south-west to north-east along or near the line of the Ohio Valley.

---

* Paper read before the Royal Meteorological Society on February 17.

The rainfall was abnormally heavy, exceeding four times the January normal between Cincinnati and Cairo, the totals for the three weeks January 6–26 reaching 12 inches at Cincinnati and 16 inches at Louisville farther down the Ohio*. The latter river rose steadily along its whole length, the rise being hastened by the abnormally high temperatures, which prevented any accumulation of snow or ice. The main stream of the Ohio was in flood on January 10, and by January 19 the floods were general. From that date conditions rapidly became disastrous. The official "flood stage" at Cincinnati is a level of 52 feet, and the highest level on record was 71·1 feet, which occurred on February 14, 1884. This record was passed on January 23, and on January 26 the level stood at 80 feet. Previous records were exceeded at all stations on the Ohio below Parkersburg, and on the Mississippi from Cairo to at least Memphis.

The crest of the flood reached Cairo, at the junction of the Ohio and Mississippi, early in February, the highest level being about 60 feet. This is nearly four feet higher than the highest crest of the great flood of 1927, which itself constituted a record. The defences of Cairo have, however, been greatly strengthened during the past ten years, and although the city was isolated and abandoned by most of the inhabitants, it did not suffer so severely as in 1927. It lay precariously in a hollow surrounded by water up to the level of the house-tops, and some damage was caused by water forcing its way through an underlying bed of sand and coming up in sudden 'sand-boils'. Farther down the Mississippi, the chief danger areas are along the tributaries entering the main river below the Ohio. These cannot be completely protected by levees, and the water floods back up them, and over the surrounding country. As a measure of precaution, thousands of people were evacuated from their homes along these tributaries in Arkansas, Louisiana and Mississippi.

By about February 5, the cities of the Ohio Valley were able to resume normal activities and the level had begun to fall at Cairo. The flood crest was now making its way slowly down the main Mississippi; but the levees were being strengthened at all danger spots, and the engineers were confident that they would hold. On February 9 the river at Memphis reached a level of 48·7 feet, more than two feet higher than in 1927, without breaking its banks. On February 10 the level at Helena, Arkansas, was about three feet above the previous record. After that date, however, the levels began to fall steadily and no further danger was anticipated.

The flood of 1937 differed from that of 1927 mainly in the area of greatest damage, which was limited to the Ohio valley instead of extending widely over the whole Mississippi below Cairo. In 1927 the Ohio valley was much less affected than in some earlier floods, especially those of 1883 and 1907. The Ohio valley is narrower and steeper than that of the lower Mississippi, and the Ohio floods both set in and pass away comparatively rapidly. This is shown by the speed of the flood crest, which normally exceeds 50 miles a day on the Ohio from Cincinnati to Cairo, compared with about 23 miles a day along the Mississippi from Cairo to Helena. The crest of the 1937 flood appears to have travelled even more rapidly, 80–90 miles a day, and this flood was therefore a relatively sudden affair, lasting less than a month. The floods of 1927 continued for two months at Cincinnati, but four or five months at Memphis and Helena.

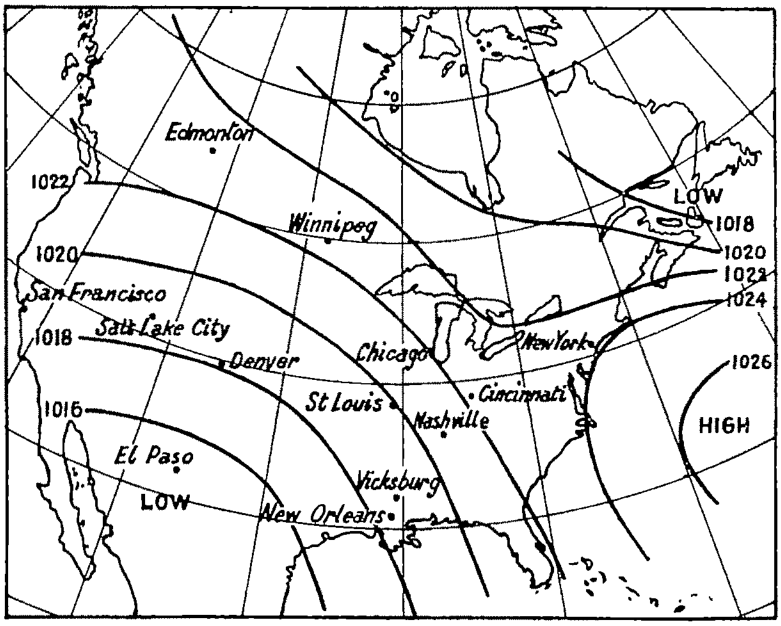

Fig. 1.

DISTRIBUTION OF PRESSURE OVER THE UNITED STATES IN JANUARY.

The great cities of the lower Ohio valley suffered severely during the recent flood. In Cincinnati and Louisville the level of the water reached to the tops of many of the houses. The supply of drinking water broke down and there was grave risk of typhoid, which actually broke out in Louisville. Petrol floating on the water became ignited, and there were several outbreaks of fire. About a million people were homeless, and though the loss of life was probably not more than five hundred, the material damage amounted to hundreds of millions of pounds.

---

* See map in NATURE, Feb 6, 1937, p 227

The meteorologists at least have not been found wanting, and it is fitting to conclude this brief account with a reference to the work of the United States Weather Bureau. The forecasts of the times and heights of flood stages were of incalculable assistance throughout to the patrols and rescue organizations. Without these warnings, the loss of property, and still more of life, would have been enormously greater.

News and Views

Prof. J. Stanley Gardiner, F.R.S.

THE retirement of Prof. Stanley Gardiner from the chair of zoology and comparative anatomy in the University of Cambridge next October will bring to an end a remarkably interesting and important period in the history of the Department of Zoology at Cambridge. At the time of his appointment, Prof. Gardiner was a leading authority on marine zoology, with a specialist's knowledge of the systematics of corals. He had gained a wide knowledge of the methods used in the exploration of the sea during the times when he took part in expeditions to the Pacific and Indian Oceans. As a result, he has been able to give most important and valuable advice and assistance to all the British expeditions for scientific oceanography from the time of his appointment to the present day. But Prof. Gardiner is a naturalist, and his extensive interests in animals and plants have given him a wide sympathy for all branches of scientific research in zoology, and therefore when the dream of an adequate zoological institute in the University became true, he saw to it that every aspect of the subject was fully provided for. The very large number of his former pupils will remember with gratitude the personal interest he took in their work, and the kindly advice and help he gave them at the outset of their careers.

Dr. J. Gray, F.R.S.

Prof. Stanley Gardiner will be succeeded by Dr. James Gray, who was one of his pupils when he became professor in 1909. Dr. Gray has had a varied career. He was demonstrator of zoology before the Great War, carrying out research on fertilization of echinoderm eggs. Then he saw war service from August 1914 until the peace, serving in France and Palestine, attaining the rank of captain and being awarded the *M.C.* Returning to Cambridge, he became Balfour student, commencing a long line of research on ciliary movement, in which he and his pupils are still interested. Lecturer and reader in turn, by a natural evolution he passed onwards to a comprehensive study of the physiology of animal locomotion, being especially interested in fish. In 1928, he was visiting professor at Columbia University. His share in the rebuilding of the whole Zoological Department at Cambridge was great, and in particular he was charged with the design of the experimental section, which contains, besides a teaching laboratory, twenty-five separate research rooms and at present overflows into the whole building. Elected to the Royal Society in 1929, he is now a member of the Council. He is also a member of the Advisory Committee on Fisheries of the Development Commission, but perhaps his greatest public service to science is in the editing of the *Journal of Experimental Biology*, which is associated with the Society of the same name.

Inauguration of an Ultra-centrifuge at Oxford

A SVEDBERG ultra-centrifuge, generously lent to the University of Oxford by the Royal Society and erected in the Department of Biochemistry (Prof. R. A. Peters), was formally set going on February 27 in the presence of a large company by the Vice-Chancellor of the University, the president of the Royal Society and Prof. The Svedberg of Uppsala himself. The cost of the complete instrument, defrayed by the Royal Society, was £2,000. The cost of its erection has been met by the University. It is one of five similar instruments, the third outside Sweden—two are at Uppsala, one in London at the Lister Institute of Preventive Medicine, and another in the United States. It is designed for the determination of the rate of sedimentation of particles of very high molecular weights. The rotor, of a nickel-chromium steel found after many trials to stand the great strain put upon it, is supported by bearings of Babbitt's metal and driven by two small oil turbines, one at each end of the shaft, which give a smooth and easily regulated run. The rotor moves in an atmosphere of hydrogen of about 25 mm. pressure. Rotation speeds, determined electrically, up to 65,000 revolutions per minute (equal to about 300,000 times gravity) can be safely attained. The solution to be centrifuged is contained as a thin column in a cell with quartz windows carried, and suitably balanced, on the rotor. The height of the column, which is about 7 cm. from the centre of rotation, does not generally exceed 27 mm. The position of the moving boundary of the particles sedimented during a run of the ultra-centrifuge is determined from photographs obtained at suitable intervals with a camera with a lens of very great focal length, the source of light being a mercury lamp. The ultra-centrifuge, which will be available for any research worker in the University, is, under the direction of Prof. R. A. Peters, in the charge of J. St. L. Philpot, Balliol College. He will employ it in a general investigation of enzymes as proteins, and particularly to see how the alteration by chemical reaction of certain groupings on the enzyme affects the stability of the particle itself.

Scientific Research in New Zealand

THE tenth annual report of the New Zealand Department of Scientific and Industrial Research covers the year 1935–36, and in addition to the Minister's statement and the Secretary's report, includes reports of the various research committees as well as of the Dominion Laboratory, the Geological Survey Branch, Meteorological Branch, and the Dominion, Apia, and Magnetic Observatories (Wellington: Government Printer, 1936. 2*s.* 3*d.*). Of the expenditure of £91,344 during the year, £46,306 was on research investigations, £11,225 of which was for industries and £21,360 in the Consolidated Fund. Plant research plays a large part in the activities of the Department, and has now been organized so that each Division is situated in the part of the Dominion most affected by its activities. General co-ordination of the work on animal health and nutrition has also been effected, and it is hoped that a comprehensive scheme of attack on these problems will be evolved during the year. A systematic soil survey of New Zealand is in progress and a survey of the tung oil industry will shortly be undertaken. Soil surveys form an important part of the investigations which are being made in the development of the citrus industry.

THE first organization to be established under the Department was the Dairy Research Institute, and this has already attacked with success certain major problems in the manufacture of butter and cheese. Strains of starter bacteria which afford the best type of Cheddar cheese have been isolated, and much information on the action of bacteria in the ripening of cheese has been accumulated. Valuable research by the Wheat Research Institute has resulted in the breeding of a new hybrid which avoids the necessity of importing strong wheats for blending purposes. An outstanding feature of the fruit research in the year has been the proving of a successful method of controlling corky-pit disease of apples by the application of boron compounds. Steps are being taken to establish research associations for various industries on the lines of those in Great Britain and also to establish a general bureau of technical information for industry. Recently the Government has taken over the responsibility for the development of industrial standards. The work of the Meteorological Office has been considerably affected by the inauguration of regular air services in New Zealand, and the system of weather observation and reporting is being considerably increased.

League of Nations and Nutrition

AT a meeting of the Expert Committee on Nutrition set up by the Committee of the League of Nations, held on December 8–10, 1936, under the chairmanship of Prof. H. Laugier, methods and results obtained as an outcome of the report on the physiological bases of the subject and a programme of research outlined, were compared and a plan of action established. Agreement was reached as to the technical methods to be applied, and a plan of future studies for co-ordination by the Health Organization was drawn up. Three methods are recommended for assessing the state of nutrition of children of pre-school age and school age and of adolescents. The first method is essentially suitable for practical work, such as the determination of the state of nutrition of large numbers of children, and for this purpose the preparation of record cards giving particulars of age, sex, physical appearance, weight and height is recommended, as well as a clinical examination of each child bearing on the colour of the skin, the state of the teeth, the condition of the subcutaneous fat layer, the state of the muscles and any signs of abnormal fatigue.

THE second type of inquiry is intended for more thorough and more scientific investigation covering smaller groups, and will include an inquiry into the child's food intake and the economic and social status of its family. A thorough medical examination and, so far as possible, special measurements and special tests, for example, on protein content of blood, pre-deficiency tests, etc. The third type of inquiry is intended to study scientifically the disturbances to which all the functions of the body are subjected when the diet is quantitatively or qualitatively deficient. A further meeting of the Expert Committee on Nutrition held on December 11–12, 1936, under the chairmanship of Prof. E. Gorter was concerned with nutritive food requirements during the first years of life. These requirements were defined as regards calories, proteins, vitamins and iron, indicating to what extent milk, cereals, vegetables, eggs, meat and broth should be used to provide a suitable diet for infants, and remarks on the quality and preparation of food were also made.

Science and Social Problems

A RECENT broadsheet issued by Political and Economic Planning (PEP) directs attention to the welcome evidence afforded by the malnutrition controversy of the recognition that science can make important and indispensable contributions to the solution of social problems. The present broadsheet merits attention not merely as presenting a concise summary of experiments and studies bearing on the known facts of nutrition, but also for a helpful discussion of the main points of controversy or misunderstanding. This is particularly true of its efforts to disperse some of the confusion caused by the use of the word 'malnutrition' in several different senses. Available evidence shows that even in the lowest income groups, shortage of calories cannot affect more than a small number of persons. On the other hand, shortage of protective food elements affects many millions, and the effective absorption as well as the actual consumption of essential food elements requires consideration. Since this is affected, for example, by exercise and fresh air, these may also be ancillary factors in nutrition. The most serious and widespread form of malnutrition at the present time in Great Britain is probably the deficiency of calcium among children and adolescents, but there is also insufficient consumption of fresh fruit, vegetables and fats, although in the present state of knowledge the deficiency cannot be measured. The most pressing nutritional needs are, however, clearly indicated, and Government and industry carry a heavy responsibility for taking the necessary steps to meet these needs. Not the least valuable feature of this admirable broadsheet is a list of reports and books on nutrition.

Roman Leicester

LEICESTER has saved her Roman remains. At a meeting of the City Council held on February 23, it was decided that the site of the Roman Forum, recently discovered in the course of the excavations carried out by Miss Kathleen Kenyon (see NATURE, **138**, 356, 432) should be preserved as an open space for all time. As the site is centrally situated and had been chosen for the erection of municipal baths, it will be widely appreciated that the citizens of Leicester by this decision have shown a generous public spirit in their attitude towards the claims of the past and a consciousness of their obligation to the nation at large and to posterity, which is worthy of all praise. Of this monument, unique in Britain, the excavations have now proceeded to a point which reveals two sides of the Forum with one of the flanking streets; while it has been shown that the famous "Jewry Wall", one of the largest pieces of Roman work in England, was part of the west wall of the basilica. In later times this became a place of Christian worship, and in the early medieval period the Jewry Wall itself was utilized as the west end of a church. Tiles and bricks from the Forum were used in the construction of the adjacent late Saxon church of St. Nicholas, itself one of the notable monuments of Leicester. It has been pointed out that in declaring that this area shall remain in perpetuity an open space, the Council preserves in the heart of the city "the veritable birth-place of her commerce, her self-government, and her religion"; but in fact it does even more. For Miss Kenyon in the course of her excavations has discovered traces of pre-Roman settlement, which may well go back to the original British village founded on the banks of the Soar. The City of Leicester is to be congratulated on a decision which will earn the gratitude of all who are interested in the preservation of such relics of the past.

An Experiment in Science Teaching

IN discussing some time ago certain aspects of university science teaching (NATURE, **129**, 773–5; 1932), doubts were expressed of the present-day necessity for, or desirability of, extensive spoon-feeding lecture and laboratory courses in universities. In proposing some changes, a plea was made for incorporating into science teaching some instruction in scientific method. An interesting development on these lines is being carried out by Prof. A. J. Riker in the University of Wisconsin in a laboratory class in plant pathology. Instead of using the same set of exercises repeated by each member of the class, the routine laboratory manipulations are acquired in carrying out simple investigations. Most members of the class work on different subjects, and compare the results freely. When a piece of work has been completed, a time is arranged and the student gives a short account and demonstration, after which the results are discussed by the other members of the class.

To facilitate the supervision, Prof. and Mrs. Riker have published in a limited edition "An Introduction to Research on Plant Diseases" (Madison, Wis.: Prof. A. J. Riker, College of Agriculture, University of Wisconsin, 1936. 2.65 dollars), giving a short account, with references to selected original papers, of the methods usually needed. Some of the chapters serve to guide the student in making his own systematic search of the literature before starting experimental work in the laboratory, in formulating his problem and his proposed plan of work clearly and in preparing an adequate report of the results. The more a method of teaching departs from a formalized routine, the more does its effect depend upon the actual supervisor, who must judge how much and how little help may be given to each individual. Much experience and analysis are then necessary before a supervisor may be able to help others to apply his new methods. Not infrequently in pioneer work the 'right' course of action may be adopted for what others may regard as a 'wrong' reason or rationalization. Since, however, there is little doubt that the methods of scientific workers could help in dealing with some of the major problems troubling present-day civilization, any attempts at developing educational methods so as to foster scientificaction deserve encouragement and close study.

Institute of Chemistry

AT the fifty-ninth annual general meeting of the Institute of Chemistry, held on March 1, the president, Dr. R. H. Pickard, stated that the membership now includes a roll of nearly 6,800 members and 800 registered students. This year, on October 2, the Institute will attain the sixtieth anniversary of its original incorporation. The ideals of its founders have been steadily pursued. Chemistry, Dr. Pickard said, has established its place among the learned professions, and its practitioners are to be found in industry and commerce, in the Government and other public services. Chemists, by the very nature of their calling, have been for the most part of a retiring and modest disposition. Happily, there are also among them not a few who have developed a measure of business acumen. That is a matter of very great significance and importance. Everything possible should be done to encourage in the profession a continuous supply of men of that type. There are, in the profession, young men, many as yet little known, who have courage and initiative to come forward with new work, to read papers, and to make useful and sensible contributions to discussions. To be able to express themselves clearly and with assurance on matters on which they can claim to know something is a valuable asset in itself. He would suggest to the younger members that much could be done to acquire this ability by good reading, by cultivating the habit of mixing with men of other professions, and by taking an active interest, not only in the proceedings of the societies devoted to their science, but also in the world of affairs generally. The supply of men and women for administrative posts is a difficult problem. There is another side of the question, however, namely, that in attaining an administrative post with the responsibility that it entails, there is a danger of the chemist losing touch with his science, so that it becomes more and more difficult for him to encourage the workers in the laboratories. Dr. Pickard was re-elected president of the Institute for the ensuing year.

Smoke Reducing Grates for Domestic Use

IN NATURE of January 23, an article on the prevention of smoke and dust emission referred to the difficulty experienced in burning raw coal smokelessly in the conventional open grate, and stated that investigations are now in progress having as their object the removal of this source of atmospheric pollution. The fundamental cause of smoke production from a domestic fire is the low temperature obtaining in the space above the fuel bed, combined with the cooling of the hot products of combustion by excess air entering the face of the grate. This normally gives rise to partial combustion of the hydrocarbon distillation products and the evolution of materials rich in carbon, but at certain periods, notably on kindling and on refuelling, the tarry matter may pass into the atmosphere unchanged.

To overcome these defects, a number of grate designs have been advanced, and the more important may be divided roughly into four classes. In the first, preheated air is supplied to the space above the fuel, increasing the temperature and promoting the early combustion of the volatile matter. This method can only be partially successful, as both the air supply and its temperature will be lowest just before adding a fresh charge. The second class, which is used in many multiple purpose grates, employs a draught which carries the distillates downwards through the hot fuel, giving conditions more suitable for their combustion. In these two, the smoke from the ignition charge is little altered. Gas is used in the third class as an auxiliary to burn the smoke. A novel example of this type was demonstrated recently by the Coal Utilisation Council, British Industries House, Marble Arch, London, W.1. The final class consists of more complicated devices in which the heat from the fire partially carbonizes raw coal contained in a suitable receptacle, the distillation products passing through the burning fuel where they are consumed. Dr. Arnot's smoke consuming grate (1855) was the forerunner of this type, but more recently a gravity feed from a hopper behind the fireback brings it more into line with modern ideas.

Control of the Grid System in Great Britain

IN a paper, read to the Institution of Electrical Engineers on February 10, Mr. J. D. Peattie describes the control rooms provided by the Central Electricity Board for controlling the generating stations supplying electricity to the grid and for supervising the operation of the transmission lines. The whole of Great Britain with the exception of northern Scotland is now divided into nine schemes. These are grouped into seven systems which are controlled from seven centres, at Glasgow, Newcastle, Leeds, Manchester, Birmingham, Bristol and London respectively. For short distances, continuous metallic circuits are provided, but for longer distances the Post Office channels pass through repeating stations and alternating current signals only are transmitted. The telephones and automatic indicating apparatus are always combined in one equipment suitable for use in conjunction with the channels hired from the Post Office. The vital line of communication is that connecting the control engineer on duty and the operator at the distant station.

IN general, the control engineer has access to, and a prior claim from his desk on, the outgoing channels. By means of automatic indicating apparatus he knows the position of the circuit breakers, the routine instruction signals and the readings of the load. In most cases the transmitting and receiving equipment for the signals are developments of apparatus used in automatic telephony. As a check on the frequency and time control carried out by the operators at the generating stations, meters connected to the local supply are installed in each control room. Differential dials are provided showing the difference between the time given by a high-grade standard clock and the system time given by the synchronous motor clocks. The standard clock is checked daily against the Greenwich radio time signal. Differential dials are also provided showing the difference between the time given by the standard clock and the system time given by a synchronous motor clock.

Recent Acquisitions at the Natural History Museum

AMONG recent acquisitions in the Department of Zoology are the mounted head of a Mexican bighorn sheep presented by Mr. John Lawson, the head of a Newfoundland caribou presented by Mr. W. Lawson, and the head of a woodland caribou presented by Captain D. A. Lawson. The study collection has been enriched by an Argali sheep skin from Samarkand, the gift of Mr. Douglas Carruthers, and a tiger skin and skull from Perak presented by the Zoological Society. Miss Emma Hutchinson of Grantfield, Leominster, Herefordshire, has presented to the Museum the collection, contained in four cabinets, of British Lepidoptera made at Leominster by her mother and other members of the family, mostly between 1860 and 1900, though Miss Hutchinson has added to it odd specimens and notes up to 1936. The specimens number some 10,000, and included with them are Miss Hutchinson's note-books in which all the records are kept. Among donations to the Geological Department is one from Mr. C. T. A. Gaster, who collected the material during many years of intensive study of the chalk of the South Downs. This collection includes 10,000 Polyzoa, 3,200 Echinoderms, 700 Sponges, 360 Annelids, 85 Mollusca, and 450 Brachiopods, and forms a valuable source of information on the succession of faunas in the Chalk. The Mineral Department has acquired by gift from Dame Maria Ogilvie Gordon, a carefully labelled series of rocks and minerals which were collected by her in the Monzoni district, Val di Fassa, Italy. She first visited this region in 1891 when on Baron von Richthofen's geological excursion. Since then she has carefully studied the structure of the western Dolomites and has made a geological map of the whole area. The present gift is a first selection of all the original material studied. Prof. S. J. Shand, of Stellenbosch University, has given a fine series of igneous rocks from localities in South Africa, South-West Africa, and Kenya Colony.

COLONEL R. H. INGHAM CLARK has placed on permanent loan in the Botanical Department of the Museum a large collection of gums. Two enormous pieces of Kauri gum, one the largest ever discovered in New Zealand, are in the collection; and one sample of Demerara Animi is the largest example known. The collection was shown at the Paris Exhibition of 1878. Since then it has been added to mainly by F. W. Fell Clark. Many of the gums are no longer obtainable, the demand having considerably decreased from a commercial point of view, and the 'workings' have reached a point where there is too much water to make the mining of gum a commercial proposition. A collection of about 1,100 Phanerogams and 50 Cryptogams from around Kangersdlugssuck at the southern end of Knud Rasmussens Land, East Greenland, has been received from Dr. H. G. Wager (British East Greenland Expedition). The importance of the collection is that it was made from inland nunataks, which has only once previously been achieved. Dr. Wolfgang von Hagen has presented seventy-three Phanerogams and nine Cryptogams from the Galapagos Islands. The Department has also received the first consignment of 420 plants collected on the Swedish Expedition to South Africa and Southern Rhodesia (1930–31) by Thore C. E. Fries, T. Norlindh and H. Weimarck.

British Science Guild

A BRIEF review of the formation and activities of the British Science Guild, including a list of subjects investigated by its committees, details of the Norman Lockyer and Alexander Pedler Lectures, the Research and Development Lectures and other lectures arranged by the Guild has recently been issued as a final statement to members. Some notes on the Parliamentary Science Committee, which has been constituted a separate body and is not included in the scheme of incorporation with the British Association, are also given. The statement gives a list of the officers and members of Council at the time of incorporation with the British Association, together with the final income and expenditure account and capital account.

An Astronomical Handbook for 1937

IN addition to the standard astronomical ephemerides, such as the "Nautical Almanac", there are published each year a few handbooks which supply, for the non-technical inquirer, astronomical tabular matter and information that is generally wanted concerning the aspects of the heavens. The 1937 edition of Flammarion's "Annuaire Astronomique" (Paris: Ernest Flammarion, 1937. 14 francs) has for some years reached the status of a modest text-book, and is an excellent example of what a non-technical ephemeris should be. An important feature of this compilation, which runs into 450 pages, is the large number of tables and diagrams, many of them conveying at a glance some fact of astronomical or of geophysical interest. This annual handbook, which is carefully revised each year so as to include the latest observations of note, should be of real use to those requiring an elementary guide to the study of the heavens.

Institution of Chemical Engineers: Medal Awards

AT the fifteenth annual corporate meeting of the Institution of Chemical Engineers, held on February 26, the following medal awards were made: Osborne Reynolds Medal to Viscount Leverhulme in recognition of his work in the interests of chemical engineering during the year 1936, especially as president of the Chemical Engineering Congress; Moulton Medal to Dr. D. M. Newitt for the paper on "The Design of Vessels to withstand High Internal Pressures" as the most valuable paper among those read before the Institution during the year (1936); Junior Moulton Medal and prize of books to Mr. Roy F. Hayman for the paper on "Corrosion", read before the Graduates and Students Section in 1936; William Macnab Medal to Mr. G. U. Hopton, for meritorious work in the Associate-Membership Examination, 1936. At this meeting Dr. William Cullen was elected president of the Institution for the year 1937.

Fitzwilliam Museum, Cambridge: New Director

MR. L. C. G. CLARKE, curator of the Museum of Archæology and Ethnology, Cambridge, has been appointed director of the Fitzwilliam Museum, Cambridge, in succession to Sir Sydney Cockerell. Mr. Clarke was appointed curator of the Museum of Archæology and Ethnology in 1922, succeeding Baron Anatole von Hügel. He has travelled extensively in Central and South America, and in Abyssinia and other parts of Africa; and he has conducted archæological excavations in New Mexico and Hungary. In addition to being recognized as an authority on the material cultures and art of the peoples of South America, he is well known as a connoisseur in art.

International Management Congress

PRELIMINARY notice has just been received of the seventh International Management Congress, which will take place in Washington during September 1938. This will be the first of the series to be held in the United States, and it will provide the most favourable opportunity which is likely to occur for many years of seeing examples of the application of American management methods to business undertakings. Two main themes are proposed for the Congress: (*a*) recent developments in scientific management; (*b*) economic and social aspects of scientific management. The papers which are accepted will be classified under one of the following six heads: administration, production, distribution, personnel, agriculture, the home. It is proposed to preface the discussions by an authoritative review of the history of scientific management up to the time of the London Congress, which will be based on reports previously prepared by each of the national committees. The organization of the British participation in the Congress is in the hands of the newly formed British Management Council, the Secretary of which is Mr. U. Baliol Scott, Armour House, E.C.1.

Scholarships in Electrical Engineering

APPLICATIONS, which must be received not later than April 15, are invited for the following scholarships awarded by the Institution of Electrical Engineers. Inquiries for full particulars and nomination forms (specifically mentioning the name of the scholarship) should be addressed to the Secretary of the Institution, Savoy Place, London, W.C.2. *Duddell Scholarship* (value £150 per annum, tenable for three years), open to British subjects under nineteen years of age on July 1, 1937, who wish to take up a whole-time day course in electrical engineering. *Ferranti Scholarship* (value £250 per annum, tenable for two years), open to British subjects under twenty-six years of age on July 1, 1937, who are students or graduates of the Institution of two years standing and desire to carry out whole-time research or post-graduate work of an electrical engineering nature. *Swan Memorial Scholarship* (value £120, for one year), open to British subjects under twenty-seven years of age on July 1, 1937, who desire to carry out whole-time research or post-graduate work of an electrical engineering nature. *Silvanus Thompson Scholarship* (value £100 per annum and tuition fees, tenable for two years), and *William Beedie Esson Scholarship* (value £120 per annum, tenable for two years, renewable in approved cases for a third year), for works employees, open to British subjects less than twenty-two years of age on July 1, 1937, for wholetime instruction in electrical engineering at an approved university or technical college.

New Fellows of the Royal Society of Edinburgh

AT the ordinary meeting of the Royal Society of Edinburgh, held on March 1, the following ordinary fellows were elected: Dr. A. J. G. Barnett, lecturer in chemistry, Education Department, Nigeria; Mr. Biswas Kalipada, curator of the Herbarium, Royal Botanic Garden, Calcutta; Dr. J. J. Black, manufacturing chemist, Edinburgh; Prof. Max Born, Tait professor of natural philosophy, University of Edinburgh; Mr. G. B. Brook, chief chemist, British Aluminium Co., Ltd., London; Mr. A. G. R. Brown, manager and actuary, Life Association of Scotland, Edinburgh; Mr. C. J. Cousland, Edinburgh; Dr. W. S. McR. Craig, Medical Officer, Ministry of Health, Whitehall, London; Dr. S. C. Dhar, head of Mathematics Department, College of Science, Nagpur, C.P., India; Dr. H. P. Donald, research assistant, Institute of Animal Genetics, University of Edinburgh; Prof. D. M. Dunlop, Christison professor of therapeutics, University of Edinburgh; Prof. R. C. Garry, Department of Physiology, University College (University of St. Andrews), Dundee; Dr. A. R. Gilchrist, assistant physician, Royal Infirmary, Edinburgh, and lecturer in therapeutics, University of Edinburgh; Dr. G. Green, lecturer in applied physics, University of Glasgow; Mr. W. A. F. Hepburn, director of education, Ayrshire Education Authority; Prof. P. R. Kirby, professor of music and musical history, University of the Witwatersrand, Johannesburg, South Africa; Dr. P. C. Koller, cytologist, Institute of Animal Genetics, University of Edinburgh; Mr. W. O. Leitch, civil engineer, Edinburgh; Dr. H. W. Melville, fellow of Trinity College, Cambridge; Mr. James Miller, Stirling; Lieut.-Colonel J. Morison; Mr. Roy Nasmith, United States Consul in Edinburgh; Mr. T. T. Paterson, fellow of Trinity College, Cambridge; Dr. J. D. Pollock, Edinburgh; Dr. B. N. Prasad, lecturer in pharmacology, P. W. Medical College, Bankipore, P.O., Bihar, India; Mr. F. I. G. Rawlins, scientific adviser to the Trustees of the National Gallery, London; Dr. M. Ritchie, assistant lecturer in chemistry, University of Sheffield; Mr. J. W. Robertson, headmaster, Central School, Aberdeen; The Hon. Lord Robertson, a senator of the College of Justice, Edinburgh; Dr. W. R. Russell, assistant physician to the Royal Infirmary and to the Deaconess Hospital, Edinburgh; Dr. J. K. Slater, assistant physician, Royal Infirmary and physician to the Deaconess Hospital, Edinburgh; Dr. A. M. Smith, lecturer in agricultural chemistry, University of Edinburgh; Mr. H. G. Smith, assistant, Department of Natural History, University of Aberdeen; Dr. H. M. Steven, divisional officer, Forestry Commission, Aberdeen; The Right Hon. the Earl of Suffolk and Berkshire, Eskbank, Midlothian; Mr. J. G. Tait, scholar of Peterhouse College, Cambridge and formerly principal, Central College, Bangalore, India; Dr. H. Tod, biochemist, West House, Edinburgh; Mr. M. McK. Turnbull, lecturer in banking, University of Edinburgh; Prof. E. M. Wright, Department of Mathematics, University of Aberdeen; Mr. A. W. Young, Writer to the Signet, Edinburgh.

Announcements

WE regret to announce the death, which occurred on February 27, at the age of seventy-one years, of Mr. W. Taylor, O.B.E., F.R.S., past president of the Institution of Mechanical Engineers, director of Messrs. Taylor, Taylor and Hobson, Ltd., optical instrument manufacturers, Leicester.

MR. R. H. BECKETT, director of public instruction, Bombay Presidency, in 1930–34, has been appointed registrar of the Indian Institute of Science, Bangalore. The appointment follows on the publication of the report of the second quinquennial reviewing committee of the Institute under the chairmanship of Sir James Irvine (see NATURE, Dec. 5, 1936). Mr. Beckett was a student of the Imperial College of Science, and entered the Indian Educational Service in 1906. He was appointed principal of the College of Science, Nagpur, in 1908, and became officiating director of public instruction and secretary for education to the Government of the Central Provinces in 1924. Mr. Beckett was made C.I.E. in 1928 and C.S.I. in 1934.

ACCORDING to *Science and Culture* (2, No. 8; Feb. 1937), Rao Bahadur K. N. Dikshit has been appointed director general of archæology in India in succession to Mr. J. F. Blakiston. Rao Bahadur Dikshit was appointed superintendent of the eastern circle in 1920; in 1930 he was appointed deputy director general for exploration and in 1935 deputy director general of archæology. He has successfully carried out archæological excavations at Mohenjo-daro, Paharpur, Mahasthan, Rangamati and a number of other places.

THE Grant Fellows in Planning at the Edinburgh School of Art recently displayed the results of two years' research in an exhibition under the aegis of the Royal Scottish Societies of Artists in Water Colour. The exhibition has now been brought to London and is to be opened at the Housing Centre, 13 Suffolk Street, Pall Mall, S.W.1, at 4 p.m. on March 10 by the Right. Hon. Arthur Greenwood.

THE Rudolf Virchow Medal has been awarded to Prof. Hans F. K. Gunther by the Berlin Society of Ethnology, Anthropology and Primeval History.

DR. HUGH S. CUMMING, surgeon-general, United States Public Health Service, has been awarded the Marcellus Hartley Gold Medal for eminence in the application of science to public welfare.

PROF. P. UHLENHUTH has been awarded the Cothenius Medal of the German Academy of Natural Philosophers for his researches on immunity and infectious diseases.

DR. FRANK G. BOUDREAU, chief of the League of Nation's service of epidemiological intelligence and public health statistics, has been appointed executive director of the Milbank Memorial Fund in succession to the late Edgar Sydenstricker.

THE American Congress of Therapeutics has awarded the "Gold Key of Merit" and the title of honorary member to Dr. Stefan Jellinek, professor at the University of Vienna, for his work in electropathology and his important contributions to the scientific development of physical therapeutics.

A MINISTRY OF HEALTH has recently been established in Paraguay by a presidential decree, under the direction of Dr. Pedro Duarli Ortellado.

THE General Education Board of the Rockefeller Foundation has given the University of Chicago three million dollars for the development of the Medical School and the improvement of the University generally.

THE Hungarian Society of Public Health, one of the oldest public health associations in the world, recently celebrated the fiftieth anniversary of its foundation, when the Archduke Josef Franz delivered the opening speech under the presidency of Dr. Daranyi.

IN spite of the vigorous campaign carried on throughout the country, the birth-rate in Italy fell from 23·1 per 1,000 in 1935 to 22·2 per 1,000 in 1936. The excess of births over deaths in 1936 was 372,577 (8·7 per 1,000) as compared with 401,833 (9·4 per 1,000) in 1935.

THE International Homœopathic League will hold a congress in Berlin on August 8–15. Further information can be obtained from the Office of the Congress, Tauentzienstrasse 7, Berlin, W.50.

THE third International Congress of Radiology will be held in Palmer House, Chicago, on September 13–17. The official languages will be English, French and German. The subscription is 20 dollars. Information regarding communications can be obtained from the president, Dr. Arthur M. Christie, 1835 Eye Street, Washington, D.C., and all other information from the General Secretary, 2561 North Clark Street, Chicago.

THE Child Guidance Council has arranged a vacation course on child psychology to be held on March 31–April 9 at Berridge House, Fortune Green Road, London, N.W. The programme will include lectures on normal emotional growth and its bearing on good mental health (Dr. J. R. Rees, Dr. Henry Wilson, Dr. Grace Calver), clinical experience in dealing with behaviour difficulties (Dr. William Moodie, Dr. R. MacCalman, Dr. Hamilton Pearson), and intellectual development and its relation to problems of learning (Miss L. G. Fildes, Mrs. Susan Isaacs, Miss M. MacTaggart and Miss C. Simmons). Further information can be obtained from the Secretary, Woburn House, Upper Woburn Place, W.C.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

The Constant of Gravitation

WITH regard to Prof. P. A. M. Dirac's recent letter to NATURE[1], I have shown, in various contexts[2] that the relation between γ, the 'constant' of gravitation, and t, the epoch, is given by

$$\gamma = c^3t/M_0, \tag{1}$$

where M_0 is the *apparent* mass of the fictitious homogeneous universe. (The *actual* mass must be infinite.) With $t = 2 \times 10^9$ years, this gave $M_0 = 2{\cdot}4 \times 10^{55}$ grams = mass of $1{\cdot}5 \times 10^{79}$ protons. Two points of interest (amongst others) emerge from the treatments I have given. First, (1) is a purely macroscopic formula, having no connexion with atomicity. It is derived from purely kinematic considerations, involving no appeal to any empirical dynamical laws, still less to atomic laws. In papers already communicated for publication, I have extended the application of (1) to all local gravitational situations and derived the inverse square law of gravitation in relativistic form in flat space, again without recourse to empirical appeals, by kinematic methods.

Secondly, the actual meaning of M_0 is that it is the mass which would occupy the sphere of radius ct with matter of density ρ_0, the density at the observer, and so

$$M_0 = \frac{4}{3}\pi(ct)^3\rho_0 = \frac{4}{3}\pi m_0 B, \tag{2}$$

where B is a constant depending on the mode of counting of fundamental particles (for example, as spiral nebulæ or smaller particles) and m_0 is the mass-number assigned to a fundamental particle. It has been shown[3] that the mass-number assigned to *any* particle may be regarded as a constant of integration. M_0 is therefore a constant. Thus there is no inference as to the creation of matter, inside stars or anywhere else. It is clear in fact that the considerations leading to (1) could never lead to any such inference, for the complete inverse square law of local gravitation (of which (1) is an intrinsic part) emerges from arguments depending on the use of Boltzmann's equation, which is a kinematic consequence of the conservation of particle numbers for any given system. We have thus $\gamma \propto t$.

When we transform the scale of time-measurement from kinematic time t to the dynamical time τ corresponding to the present epoch t_0 by the formula

$$\tau = t_0 \log (t/t_0) + t_0, \tag{3}$$

and adjust the measures of all derived quantities accordingly[4], γ reduces to a constant γ_0, and is given by $\gamma = \gamma_0 (t/t_0)$. The usually adopted constancy of γ_0 is thus connected with our habitual use of a dynamical scale of time.

Relation (3) is not, of course, a transformation of co-ordinates but a re-graduation of the fundamental observers' clocks. The associated transformation of co-ordinates is readily found. It then appears[5] that this transformation leads to the relation $ds = e^{(\tau-t_0)/t_0}\, d\sigma$, where $d\sigma^2 = d\tau^2 - c^{-2}d\varepsilon^2$ and $d\varepsilon^2$ is the metric of the static, infinitely extending hyperbolic space into which the interior of $r = ct$ transforms. The epoch co-ordinate τ of *any* event is an invariant, the same by whatever fundamental observer it is measured, and it enjoys all the properties of a world-wide Newtonian time; and $d\sigma$ may be taken as the interval between two events with the same justification as ds. These results confirm Dirac's remarks at the end of his letter.

Note added in proof, Feb. 26. Complete agreement between Dirac's results and kinematic cosmology can be obtained, and his proportionalities $M \propto t^2$, $\gamma \propto t^{-1}$, replaced by $M = \text{const.} = M_0$, $\gamma \propto t$, if we take the 'electrostatic' constant γ' in the inverse square law to be proportional to t; γ' is, of course, usually taken as unity. This is formally the same as taking $e^2 \propto t$. The t-dynamics then gives the radius of the Bohr atom as proportional to t, and a material rod is 'rigid' on the τ-scale. Electrostatic forces then become to some extent analogous to gravitational forces, and might be discussed kinematically by examining the properties of an expanding sphere of mingled positive and negative particles.

E. A. MILNE.

Oxford.

Scotopic Luminosity Curve and the Absorption Spectrum of Visual Purple

ALTHOUGH it is generally accepted that visual purple plays an essential part in the process of scotopic vision, attempts[1] at relating the *human* scotopic luminosity curve (for equal energy spectrum) with the extinction (absorption) coefficient curve of *amphibian* or *mammalian* visual purple have shown a difference in the wave-length position of the maxima. Hecht and Williams[2], using a 'constant stimulus' method, found that the maximum of this luminosity curve was at 510 mμ. This was a mean value for forty-eight young observers, and there was little variation. Abney and Watson[3], using a threshold intensity method, found that the maximum of the luminosity was at 505 mμ for three monochromats.

Most experimenters have found maxima for the extinction coefficient of visual purple solutions between 500 mμ and 504 mμ. König[4] found a maximum at 500 mμ for human visual purple. Recently, Lythgoe[5], using an improved technique[6] and carefully purified specimens, has found the maximum for *Rana esculenta* to lie at 502 mμ. His measurements were made against a blank of the solvent, a solution of digitonin (colourless).

Hecht and Williams explain the difference in the position of the maximum of luminosity and of extinction by supposing that in the eye the visual purple is dissolved in a substance of high refractive index, when according to Kundt's rule, the absorption spectrum would be displaced towards the red with respect to an aqueous solution of visual purple. Kundt's rule is untrustworthy, and in any event, before a comparison can be made, it is essential to consider the physical (dimensional) relation between the two factors, luminosity and light absorption.

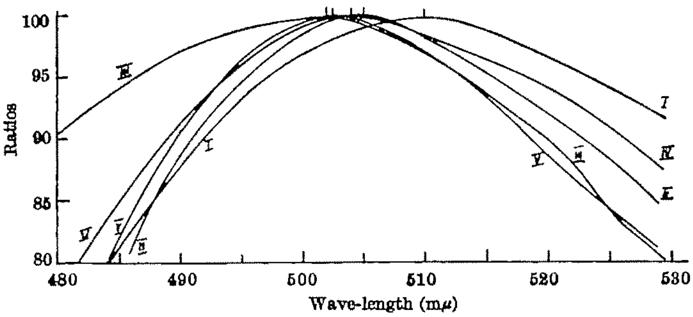

Fig. 1.

Scotopic luminosity curves. Energy basis, I, Hecht and Williams, and II, Abney and Watson; Quantum basis, IV, Hecht and Williams, and V, Abney and Watson. Curve III shows the extinction coefficient of visual purple, Lythgoe.

Evidence continues to accumulate indicating that the primary part of the physico-physiological process in scotopic vision is photochemical[7]. Thus the relative luminosity, R_λ, should be represented not on the basis of an equal *energy* spectrum but on that of an equal *quantum intensity* spectrum. This may be effected by multiplying the figures for the relative scotopic luminosity (energy basis) by the value of the quantum at the wave-length in question. This has the effect of shifting the maxima from 510 mμ and 505 mμ to 504 mμ and 502 mμ respectively, as shown on a large scale in Fig. 1. Thus reduction to the quantum basis discloses that the curve of the extinction coefficient of visual purple and the curve of relative scotopic luminosity have effectively coincident maxima. This supports the contention that the primary process in scotopic vision is the absorption of light *quanta* by visual purple.

In order to extend the relation between the two curves it is necessary to consider the following points. According to the above definition of the relative luminosity, equality of the stimuli produced by light of two different wave-lengths implies equality of the values of $R_\lambda I_\lambda$, where I_λ is the intensity of light in quanta per second at the wave-length λ, given by the instrument used. If almost any simple photo-chemical mechanism were assumed, the stimulus would be a function of the intensity of light *absorbed*, I_a, at each wave-length, that is, equality of stimulus arises from an equality of I_a. The value of R_λ would, therefore, be proportional to I_a/I_λ, which in turn is given by

$$I_a/I_\lambda = 1 - e^{\alpha c} \quad . \quad . \quad . \quad (1)$$

where c is the areal concentration in chromophore groups[7] per sq. cm. and α the extinction coefficient per chromophoric group. αc is simply 2·3 times the usual optical density ($\log_{10} I_0/I_T$). If, therefore, we know the optical density of visual purple in the dark-adapted eye for wave-length 502 mμ, we can calculate the relative intensities of the light absorbed at the other wave-lengths.

Unfortunately, there are no trustworthy measurements of this density. Konig[4] extracted visual purple from a human eye in an amount sufficient to cover the retina to an optical density of 0·018 (λ = 500 mμ). This value is probably much too low owing to decomposition before extraction and incomplete recovery of the visual purple. In the course of our experiments with visual purple solutions carried out in conjunction with Dr. R. J. Lythgoe, we have calculated that at complete dark adaptation the optical density in a frog's eye (*Rana esculenta*) at the maximum is not less than 0·1. For the purposes of argument a value of 0·1 will be assumed for the dark-adapted human eye, but should this value be incorrect by as much as a factor of two, the argument below is not appreciably affected.

The densities for other wave-lengths have been obtained by combining the relative extinction coefficient curve with the above value for the density at 502 mμ (that is, solving for c equation (1); in arbitrary units). The fraction of the incident light which is absorbed, I_a/I_λ, has been calculated relative to the value at 502 mμ (where it has been taken as 100 units), and the results plotted as shown in Fig. 2.

It will be seen that on the red side of the maximum the 'light absorbed' curve agrees well with the luminosity curve of Abney and Watson and in part with that of Hecht. If the value for the density of the visual purple in the eye is an acceptable one, the contention that the primary process in scotopic vision is photochemical is strengthened by this agreement.

On the blue side, the luminosity curve lies well below the 'light absorbed' curve. This would be expected for a number of reasons, only a few of which need be mentioned here. It is well known that yellow substances are present to a considerable extent in the retina. These are probably visually insensitive, but will affect the luminosity curve by absorbing the light below a wave-length of about 500 mμ, thus reducing the amount absorbed by the visual purple in this region. This probably accounts for most of the difference in the curves. Yellow substances in the eye lens may sometimes have an important effect.

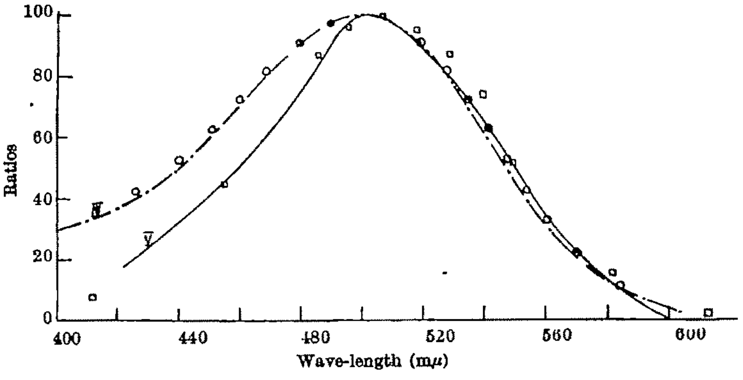

Fig. 2.

Curves III and V as in Fig. 1. Squares, as Curve IV, Fig. 1. Circles, light absorbed by visual purple (calculated).

If in place of the absorption curve as shown, one uses the curve from which has been subtracted the absorption of the bleached solution (as is usually done), the difference in the blue is much reduced. Such a 'correction' is, however, meaningless, as visual purple bleaches to a yellow substance, and the resultant curve depends largely on the yield and stability of this substance. The yellow products of visual purple may themselves be partly responsible for the low luminosity in the blue. The curve obtained by Dr. Lythgoe may include absorption due to a small amount of residual impurities, but is much more trustworthy than the 'corrected' curves.

Sharpness of the Magnetic Curie Point

EXPERIMENTS carried out in recent years on nickel and iron have led to the view that the spontaneous magnetization does not disappear suddenly at the Curie point, but that there is a definite 'tail' to the magnetization-temperature curve. The specific heat measurements of Ahrens[1], and more particularly the work on very pure nickel by Grew[2], establish beyond doubt that the energy (E) associated with the ferromagnetic state does not vanish suddenly at the Curie point, although there is probably a sharp discontinuity in the $(d^2E/dT^2, T)$ curve at this temperature. The measurement of the energy, either through the specific heat or the magneto-caloric effect, appears to us to be the only sound method of estimating the degree of spontaneous magnetization.

Recently, Svensson[3] has measured the resistance of nickel near its Curie temperature and finds a discontinuity in the temperature coefficient taking place within a temperature range so small as 0·1° C. One of us (H. H. P.) has recently repeated and verified this result, and has also shown that from the Curie point (357° C.) up to a temperature of 1,000° C., the resistance-temperature curve is concave to the temperature axis with a very marked curvature for some 30° or more above the Curie point. We wish here to suggest a means of reconciling the results of the experiments on the change of magnetic energy with those on the change of resistance.

The magnetic state is determined by the degree of order among the electron spins, the disappearance of the ferromagnetism being associated with the break-up of the Weiss domains. Now the magnetic energy must depend on the interactions between spins at close range or, in other words, on short-distance order. On the other hand, since the mean free path of an electron in nickel at its Curie point is of the order of 20 times the interatomic distance, the resistance will depend on long-range order. If at a definite temperature (Curie point), order suddenly ceases to extend over domains of more than about 8,000 atoms, a kink in the resistance-temperature curve will be obtained; but owing to the presence of smaller ordered domains the magnetic energy will not have vanished completely.

The effect of the subsequent break-up of these smaller domains is to produce the 'tail' of the magnetization-temperature curve, and a marked curvature in the resistance-temperature curve in the region immediately above the Curie point.

The continued concavity of the resistance curve towards the temperature axis up to 1,000° C. is due to quite another cause; it occurs also for paramagnetic metals, and has already been explained by one of us[4].

It may be noted that Stoner[5] has used a similar idea of small ordered domains persisting above the Curie temperature to explain certain apparent anomalies in the magneto-caloric effect.

Constitution of the Keratin Molecule

FROM a study of the elastic properties of wool fibres in solutions of varying hydrogen ion concentration, Speakman[1] has argued that the long peptide chains of wool are bridged by salt linkages formed from the acid side chains of aspartic and glutamic acids, and the basic side chains of arginine, lysine and histidine. In addition, chemical equivalence between the *free* acid and basic side chains was deduced from the form of the curve relating the ease of fibre extension to the pH of the medium. Such is the salt linkage theory, for which support was later found in the titration curves of wool[2] and feather keratins[3], as well as in deductions concerning the influence of the salt linkages on the reactivity of the disulphide bond in strained animal fibres[4]. Unfortunately, however, the amounts of aspartic and glutamic acids isolated from wool and goose feather by Abderhalden[5] are insufficient to account for the basic side chains as well as amide nitrogen. The difficulties of protein analysis are so great that the salt linkage theory is not called into question by Abderhalden's results, but it was felt desirable to augment the supporting evidence already available by direct proof based on new determinations of the dicarboxylic acids in wool and seagull quill, which may be regarded as typical keratins.

Using modifications of Foreman's[6] and Jones and Moeller's[7] procedures, which will be described elsewhere, the following data, corrected for nitrogen loss at different stages of the investigation, were obtained for Cotswold wool.

Acid	Amount isolated expressed as: per cent on weight of wool	mgm.N/gm. of wool
Glutamic acid	15·27	14·54
Aspartic acid	7·27	7·65
	Total N =	22·19

When uncorrected for loss of nitrogen, the total dicarboxylic acid nitrogen was 20·75 mgm./gm., so that correction, being small, is justified. The amide nitrogen content of the wool was found to be 13·7 mgm./gm., leaving dicarboxylic acid equivalent to 8·49 mgm./gm. available for combination with the basic side chains. Taking Vickery and Block's[8] determinations of the basic amino acids in wool, the excess dicarboxylic acid required for combination according to the salt linkage theory is 8·55 mgm.N/gm. Vickery and Block's results are probably low, but even if the maximum combining capacity of wool for hydrochloric acid is taken as a measure of the basic amino acid content, the amount of dicarboxylic acid needed for combination is only 11·2 mgm.N/gm. In other words, we have succeeded in isolating 22·19 out of the maximum possible requirement of 13·7 + 11·2 = 24·9 mgm./gm. of dicarboxylic acid nitrogen.

The methods employed in the preceding investigation were evolved during a preliminary attempt to determine the dicarboxylic acid content of seagull quill. According to the salt linkage theory, the quill should contain 20·6 mgm./gm. of dicarboxylic acid nitrogen, comprising 14·9 mgm./gm. for amide nitrogen and 5·7 mgm/gm. for basic side chains as deduced from the acid combining capacity. In the case of goose feather, however, Abderhalden[5] succeeded in isolating only 2·3 per cent of glutamic acid and 1·1 per cent of aspartic acid, together equivalent to 3·4 mgm.N/gm. When corrected for nitrogen loss as before, the quantities isolated in the present investigation were as follows:

Acid	Amount isolated expressed as:	
	per cent on weight of feather	mgm N/gm. of feather
Glutamic acid	9 72	9·26
Aspartic acid	6·57	6·92
Not identified	—	0·96
		17·14

The amounts of aspartic and glutamic acids are an improvement on Abderhalden's values, and the agreement between the nitrogen content of the isolated dicarboxylic acids and the requirement of the salt linkage theory is sufficient to establish its validity for feather, as well as for wool, if due account is taken of the preliminary character of the feather investigation.

Chromatin Arrangements in Spore-forming Bacilli

WE have recently made a cytological study of several species of spore-forming bacilli, using the vital staining method of Nakanishi as modified by Stoughton[1]. This has resulted in two observations which help to explain (1) the confusion of ideas as to the changes in cell structure accompanying spore-formation, and (2) the role of the spore in the cycle of development of the bacillus.

(1) In young cultures (purified by plating, followed by single cell isolation), prior to the appearance of spores, many cells show a sharp lateral division into two sections depending upon a difference in affinity for the stain (for example, neutral red chloride). One section (usually rather less than half the cell) is deeply stained, the other section very lightly and in many cases apparently not at all. This appearance (shown by the top cell in the photomicrograph reproduced as Fig. 1, *a*) has been found to be typical in the case of six spore-formers—two isolated from silage, one from soil, one found as a contaminant in a medium and two stock cultures (*B. subtilis* and *B. megatherium*)—otherwise easily distinguishable on physiological grounds.

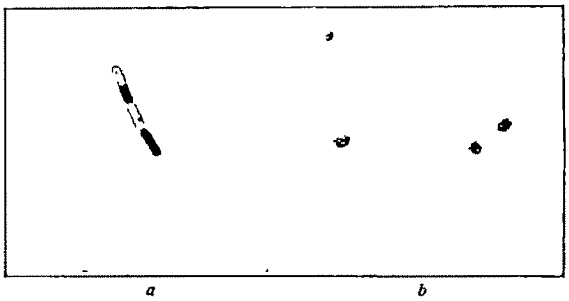

Fig. 1.

Observations on cultures of a slightly more advanced age indicate that the cell containing the two sections undergoes fission in the usual way, giving rise to one cell capable of staining deeply and one which has little or no affinity for stain (as shown by the two lower cells in Fig. 1). Further observations in the case of three of the above cultures have led us to the conclusion that the two kinds of cells thus produced differ in their subsequent cytological development, resulting in each case in a cell containing an endospore but with a different structure extraneous to the spore. These alternative methods of forming endospores shown by the same species of organism may possibly explain to some extent the divergence in descriptions of the process of spore-formation by different authors.

(2) As is well known, the fully formed bacterial spore, examined by ordinary methods, appears as a refractile body resistant to the entry of stains, and it has been generally assumed that it is in fact homogeneous and represents a resistant resting stage in the life of the bacillus. So far as we are aware, there is no record of experimental evidence to refute this view, and the only suggestion found in the literature is one by Mellon (quoted by Hadley[2]) that the bacterial spore may be a 'cover' for nuclear reorganizations.

In the case of two of the above species of spore-formers, both isolated from silage, structures visible by vital staining methods have been followed at frequent intervals until the cultures were several weeks old. This has disclosed the fact that endospores, though certainly refractile for some time after formation and subsequent release from the enclosing cells, may later take up the stain and reveal a deeply staining granular structure. This shows rearrangement into several definite forms over a considerable period of time. In some spores showing an internal structure the stain is absorbed quickly, in others the structure appears more slowly after leaving the spores in contact with the stain. One such appearance is shown in the photomicrograph reproduced as Fig. 1, *b*.

These appearances suggest that, in some instances at least, the bacterial spore certainly has a function other than that of a resistant resting stage, namely, that it provides an opportunity for rearrangement of chromatin material.

Development *in vitro* of the Mammalian Gonad

IN recent experiments the entire mammalian gonad has been successfully cultivated *in vitro* and the explants continued to differentiate during cultivation.

The ovary and testis from young and embryonic rats and mice were grown by the watch-glass method on the surface of a clot composed of equal parts of fowl plasma and fowl embryo extract. For each culture, one gonad was fixed as a control.

A typical maturation division figure was observed in an explanted ovary from a four-day (post-embryonic) rat after 9 days' cultivation (Fig. 1). The appearance of the figure was preceded by an actual growth of the ovum.

Small, normal Graafian follicles differentiated *in vitro* in the ovaries of two 19-day rat embryos and of three new-born mice, although the controls showed that at the time of explantation the germinal tissue was in the form of sex cords and contained no Graafian follicles. Some of these follicles remained healthy after twenty-two days *in vitro*. Many residual ova survived *in vitro* for an equally long time. After a month *in vitro*, the organ degenerated.

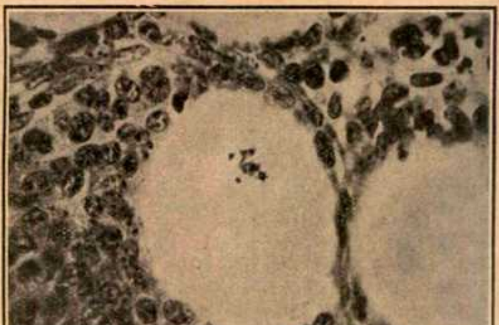

Fig. 1.

OVARY FROM A FOUR-DAY (POST-EMBRYONIC) RAT AFTER 9 DAYS' CULTIVATION *in vitro*. (ALLEN'S MODIFICATION OF BOUIN'S FLUID; MAYER'S HAEMATOXYLIN. × 640.)

The testis also grew and differentiated *in vitro*. In the explanted testis of a new-born mouse, spermatocytes in the typical pachytene phase of the meiotic prophase had developed *in vitro* after 11 days' cultivation (Fig. 2), although only spermatogonia were present at the time of explantation. Similar spermatocytes were also observed in the explanted testis of a 17-day mouse embryo after 16 days *in vitro*.

So far, spermatogenesis *in vitro* has always stopped at the pachytene stage of meiosis, although female germ cells growing under the same conditions seem to pass through this phase without difficulty. This point requires further investigation.

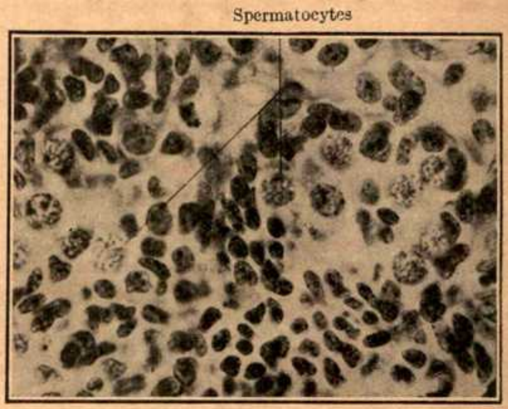

Fig. 2.

TESTIS OF A NEW-BORN MOUSE AFTER 11 DAYS' CULTIVATION *in vitro*. TYPICAL SPERMATOCYTES SHOWING CHROMATIN FIGURES OF THE EARLY MEIOTIC PROPHASE HAVE DIFFERENTIATED *in vitro*. (ALLEN'S MODIFCATION OF BOUIN'S FLUID; MAYER'S HAEMATOXYLIN. × 640.)

Many seminiferous tubules maintained their original form for as long as 17 days' cultivation, but the germ cells mostly degenerated by the twentieth day *in vitro*.

The results so far obtained have provided a new experimental approach to several problems of sex physiology.

Metamorphosis of the Larva of *Ostrea edulis*

ALTHOUGH we now have a complete description of the fully-developed larva[1] of the European oyster (*Ostrea edulis*), we have as yet no account of the metamorphosis which takes place when the larva attaches itself and becomes the settled spat. The smallest spat yet described is that figured by Yonge[2]. The shell of this individual measured 1·2 mm., whereas the shells of fully-developed larvæ before settlement average only 0·30 mm. There is therefore a considerable gap which requires to be bridged by the description of smaller spat.

I have been able to obtain a number of such early stages attached to glass slides, and, with the addition of further material during the coming season, it may be possible to prepare a complete description of the metamorphosis. The material already collected shows the evolution of the posterior adductor as the one shell muscle, and the development of the gills. The fully-developed oyster larva, as described by Erdmann[1], possesses anterior and posterior adductor muscles about equal in size and symmetrically placed with regard to the hinge. At this stage the rudiments of six gill filaments on the left side are shown by Erdmann. The earliest settled spat that I have yet examined, which possesses the larval shell (prodissoconch) only, without any fringing growth (dissoconch), has seven gill filaments on this side. In this spat the anterior adductor already shows reduction and, with the increase in size of the posterior adductor, the ratio between the two is already 3 : 2 in favour of the latter.

During the first eighteen hours after settlement, the spat retains the 'eyespots' which are so characteristic of the fully-developed larva, and such 'eyed' spat usually have eight gill filaments on the left side with a suggestion of the ninth. The 'eyespots' disappear within twenty-four hours of settlement, and at forty-eight hours a fringe (dissoconch) has been added to the larval shell. The spat at about forty-eight hours after settlement measures about 0·35 mm. and possesses ten gill filaments on the left side, while still showing distinct vestiges of the foot and velum. The fate of these larval organs in the American oyster (*Ostrea virginica*) has been described by Stafford[3], but we have no information concerning their fate in *Ostrea edulis*. The eleventh, twelfth and thirteenth gill filaments appear on the left side before the spat is ninety hours old, and such spat usually show the anterior adductor reduced to a few fibres at the edge of the shell, or absent altogether. The posterior adductor has increased in size and its point of attachment has moved ventrally until it lies almost outside the prodissoconch attached to the dissoconch, the definitive shell of the adult. Such ninety hours old spat may be 0·6 mm. in diameter, that is, with a shell twice the diameter of that of the larva. The foot and velum are completely absorbed and there are 13 gill filaments on the left and 7 on the right. The smallest spat described by Yonge[2] had 20 filaments on the left and 13 on the right and its shell measured 1·2 mm. It is probable that it had been attached for five or six days.

Light and Breeding Seasons

IT has recently been shown by Marshall and Bowden[1] that not only duration but also intensity of illumination can affect the onset of a breeding season, and that ultra-violet as well as visible light is effective. These discoveries have an important bearing on seasonal phenomena in the tropics.

On the equator itself the length of day is always the same, and in the equatorial regions the seasonal change is small. (As my brother, Mr. S. J. Baker, points out, the difference in minutes between the longest and shortest day in the tropics may be found by multiplying the latitude in degrees by 7·2. The result is always correct within two minutes between 20° N. and 20° S.) Despite a constant or almost constant length of day, not very many equatorial birds are known to breed all the year round. One may suppose that the control is by intensity of illumination (visible and ultra-violet).

It is an interesting fact that, of those species of birds in Ceylon the breeding seasons of which are known, no fewer than eleven definitely have two breeding seasons annually, and at least sixteen other species probably behave in the same way. The length of day, of course, only rises to a maximum and sinks to a minimum once annually, but the intensity of illumination probably has two maxima in the year, at about the times when the sun passes overhead. Although these are often times of heavy rainfall, yet the mornings and early afternoons tend to be sunny. In South America in nearly the same latitude as Ceylon, it has been shown that there are two periods of maximum intensity of ultra-violet light in the year, in May and October (Chavarria and Gomezvega[2]). Similarly, Harrisson and I[3] have shown that in the tropics of the southern hemisphere the amount of ultra-violet light sinks to a low figure when the sun is near the Tropic of Cancer.

Those birds of Ceylon which have two breeding seasons commonly breed at about the times when one must suppose that the intensity of illumination is near its maxima. To take only one example, the Ceylon blackbird, *Turdus merula kinnisii*, breeds in March–April and again in September[4].

Extent of the Ranikot Sea

WITH reference to my preliminary note[1] on the results of work by Mr. Pinfold and myself on the Eocene beds of the Punjab Salt Range, we have now determined the fact that, of the six sections of the local Eocene, the lower three (Dhak Pass Beds, Khairabad Limestone and Patala Shales) are all of Upper Ranikot age ; the Patala Shales representing later Ranikot elements than have yet been found elsewhere. The three upper sections (Nammal Shales, Sakesar Limestone and Bhadrar Beds) are of Lower to Middle Laki age, the unconformity between Ranikot and Laki being rather less on the Salt Range than elsewhere. Our paper on this subject, giving full palæontological details, will appear in due course as the first part of vol. 24 (N.S.) of the *Palaeontologia Indica*.

We have meanwhile studied the Eocene rocks of Waziristan, and the Kohat and Attock Districts, in order to determine the further extensions of these beds to the north and north-west. I also examined the late Sir Henry Hayden's collections from the Cretaceous and Eocene beds of Kampa Dzong in Tibet, due north of Calcutta. Certain of these beds were referred to the Danian by Prof. H. Douvillé in 1916 ; but Dr. G. de P. Cotter, of the Geological Survey of India, afterwards argued that they more probably belong to the Laki. I found that they are really of Upper Ranikot age, their foraminiferal fauna agreeing in closest detail with that of the Khairabad Limestone of the Punjab Salt Range.

It has thus become obvious that the Ranikot Sea, once thought to have been limited to a small area in western Sind, not only reached northwards as far as the Tirah, but also extended thence to the east over the whole length of the Himalayas, as far, at least, as the longitude of Calcutta. The peculiarly rich and characteristic Ranikot foraminiferal fauna has not, however, yet been traced far to the west; and its distinction from the contemporary faunas of Europe indicates that Indian waters formed a separate zoological province in Palæocene times. Many European species appear in the succeeding Laki, however, and the foraminiferal fauna of the Khirthar is very similar to that of the Lutetian. Thus the isolation of Indian waters during the early Tertiary appears to have been limited to the Palæocene.

Racial Theory and Cross-breeding

CROSSES have been the great stumbling block in the path of physical anthropology. Different races can and do breed together, therefore there can be no such thing as a race of men, if by race we mean the human equivalent of a breed of dogs or horses. Anthropologists allow an exception where deserts or other obstacles isolate one lineage from another.

They overlook the possibility that man may be isolated by his own action, by his language, his custom, even by his own decision. In practice, lineages do isolate themselves for breeding purposes where there is no external necessity, just because they like to do so. Not being a physical anthropologist, I have not pursued the facts systematically from the point of view of breeding, but such facts as have come my way in the pursuit of other aims seem to raise two questions which have not been given proper consideration:

1. Is cross-breeding really common?
2. Does such cross-breeding as takes place leave much trace in the long run?

1. In a commune near Alexandria, 'Ali Ahmed 'Isa Eff. counted 53 marriages in two years, of which 23 were within the village or hamlet; 7 were outside the village or hamlet, but within the commune; 13 were outside the commune, but into neighbouring communes; 10 were into towns round about. It is common knowledge that English peasants used until recently to view with disfavour marriages with 'foreigners', that is, strangers to the village.

I can only record the impression left by a Guernsey pedigree now unfortunately lost. Marriages went on mostly within a small group of families. First cousin marriage between two of those families never failed for several generations. Of three marriages I remember outside the circle, all encountered opposition.

Writings on exogamy have encouraged the idea that it means compulsory breeding out. As a matter of fact, it is generally not a system of enforcing marriage outside the family, but of restricting it to another branch than one's own, exactly as happened between the two Guernsey families above (cf. *Genesis*, xxiv and xxviii, and my "Progress of Man", 239 ff.). The exclusiveness of Indian lineages is notorious and extreme, and they constantly split up into lineages exclusive of one another.

These are only a few of the facts.

2. Anthropologists get their impressions from middle-class practice. This class is addicted to promiscuous breeding; in fact, it may be said to be characteristic. The middle classes, however, appear to be dying out, not for the first time in history (see notably S. Dill, "Roman Society in the Last Century of the Roman Empire"). It seems doubtful whether townsfolk generally last many generations. We know that towns are constantly recruited from the country. This is particularly so in Paris. Eventually, towns dwindle and sometimes disappear altogether.

To take a concrete case. The North Central Province of Ceylon was once thickly populated all around an extensive capital. It is now reduced to a miserable remnant of peasants living in small hamlets. From whom are they descended? From the ancient city population? But we have no evidence that city populations ever return to the soil in any numbers, if at all. They can only be descended from the peasants. That is only one of countless cases.

This brings us face to face with a phenomenon which is seldom faced because it is not pleasant. Communities flare up and die down. Therefore only a small fraction carries on the breed. Who? There is every appearance that it is the peasantry, which is most given to self-imposed isolation.

We can no longer be content to note that cross-breeding occurs; we must *observe* its consequences for generations, instead of *assuming* them.

Perhaps if we do so we shall find out a great deal more than by the study of animals, which is experimental, and so works under the unnatural conditions of the laboratory. In observing man, we observe what happens in Nature. When we watch human lineages isolating themselves, we may get the clue to the segregation of species in Nature.

Negative Protons in Cosmic Radiations

AT Asmara, magnetic lat. 11° 30′, Rossi[1] and Benedetti[2] have counted the number of coincidences between two counters mounted with their axes parallel in such a way that the plane containing them could be rotated about a parallel axis so as to make any given angle with the vertical at the point. They have measured the diminution in the number of coincidences caused by introducing lead between the counters, and also by rotating the plane of the counters so as to make various angles θ with the meridian plane. Certain conclusions follow from these experiments which we shall now deduce.

Benedetti has measured the number of coincidences in the following three cases:

Arrangement.	Thickness of lead between the counters.	Angle θ to the west.	Rate/minute.
(1)	4 cm.	0°	$0{\cdot}625 \pm 0{\cdot}010$
(2)	16 cm.	0°	$0{\cdot}575 \pm 0{\cdot}009$
(3)	4 cm.	30°	$0{\cdot}516 \pm 0{\cdot}009$

The decrease between (1) and (3) is about twice the decrease between (1) and (2). Since at the height of Asmara 12 cm. of lead corresponds in mass to the extra thickness of atmosphere in going from the vertical to $\theta = 30°$, the difference between (1) and (3) might be ascribed to the greater absorption due to the same mass of air. This possibility can, however, be excluded by the experiments of Street, Woodward and Stevenson[3], who have measured the absorption in lead, iron and marble, and of Clay and his co-workers[4], who have measured it in various substances including water. These investigators find that, to within a few per cent, all these substances absorb the hard radiation proportionately to their mass. It is impossible that air[5] should absorb essentially differently, so that we are led to the conclusion that the larger difference between (1) and (3) is due to the fact that, *before entering the atmosphere*, the number of particles arriving in a direction 30° to the west of the meridian is appreciably less than the number arriving vertically. This can only be due to the magnetic field of the earth, if there are *negatively* charged particles present.

These negative particles may be electrons or *negative* protons. The possibility that the smaller number of coincidences in (3) may be due to the intensity at the top of the atmosphere of electrons in a direction 30° west being smaller than the vertical intensity can be excluded at once, *provided these electrons behave in accordance with the theory*. For in order that this should be the case, at least the difference between (2) and (3), that is, more than 10 per cent of the number of coincidences in (2) with 16 cm. of lead between the counters, must be attributed directly or indirectly to them. It now follows from a recent paper[6] where successive processes of emission of radiation and pair-creation by γ-quanta have been treated according to quantum mechanics, that the absorption in 12 cm. of lead is so great that the number of coincidences with 4 cm. of lead, namely in case (1), should be at least a thousand-fold this difference, which is in flat contradiction to the actual observation. The results of Benedetti then force us to one of the two following conclusions.

(1) Extremely high energy electrons do not behave in accordance with the theory, and in particular, the radiation formulæ of quantum mechanics break down for these high energies.

(2) There are negative protons in cosmic radiation in considerable numbers, or alternatively, some other negatively charged particles hitherto unknown to physics.

I believe that sufficient experimental evidence,[7] direct and indirect, has accumulated by now to exclude the first possibility, particularly when taken in conjunction with the fact that the theoretical arguments showing that the theory should hold for all energies are sounder than any against the validity of the theory. It seems, then, that we are compelled to admit the existence of negative protons or new negative particles in appreciable numbers in cosmic radiation.

That we are forced to choose between the conclusions (1) or (2) is indeed not new, and follows also from a number of other observations, for example, the power some negatively charged particles have of apparently penetrating great thicknesses of lead[7]. The interest in the above considerations, however, lies in the conclusion that *negative primaries* entering the top of the atmosphere are responsible in part for the *penetrating* component of cosmic radiation.

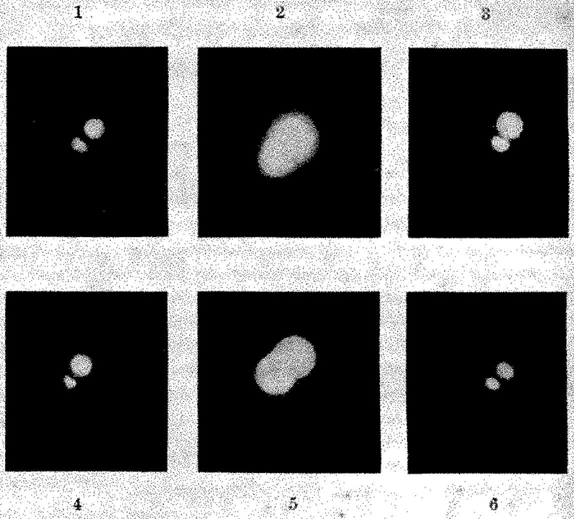
Diffraction Experiments on the Resolving Power of Telescopes and Microscopes

THE diffraction of light on a circular aperture in a thin opaque screen has been studied by G. B. Airy[1], E. Lommel[2] and many others after them. The experiment is of fundamental importance for the theory of the image formation in optical instruments. The formula given by Airy has been but little modified, and in its present form (Preston[3]) is:

$$X = 0{\cdot}5F\frac{\lambda}{d},$$

where X is the minimum separable distance between two neighbouring disks, representing points of the object, λ the wave-length of the light, F the focal length and d the diameter of the lens.



DRAWINGS BY W. TH. SHEILLS AFTER PHOTOGRAPHS ENLARGED 4 TIMES.

Experiments with virus bodies, the size of which was below the limit of resolution given in the above formula, led to investigations of the experimental basis of that formula. It had been observed that reduction of intensity shows details that should not be visible in some cases and not resolvable in other cases if the formula was strictly right.

Compared with Airy's and Lommel's arrangements, one alteration was introduced, namely, instead of one hole in the opaque screen two holes were used. These two holes were observed in a telescope with an aperture variable by means of an iris diaphragm. A carbon arc served as a light source. White light as well as that of different wave-lengths was employed for the experiments. Photographs of the image were obtained by fitting a camera on top of the eyepiece of the telescope.

Fig. 1 shows the two holes in the screen as they appear with a large aperture of the telescope. The shape of the holes is well defined.

Fig. 2. The same holes illuminated with white light of higher intensity: the shape of the holes is not distinguishable.

Fig. 3. The intensity of the light is reduced again to that of Fig. 1, and the aperture of the telescope is reduced so far that the shape of the holes just cannot be discriminated.

Fig. 4. By the introduction of two polarizing prisms (Polaroid screens) into the path of the rays,

the intensity of the light was reduced until the threshold of the eye was reached for the minimum visible light intensity: the shape of the holes could be recognized and recorded photographically to a certain extent.

These experiments show that structure in the object can be resolved with an aperture of the optical instrument smaller than that postulated by the formula. Therefore it was desirable to test whether two points could be separated if their distance is too small to be separated otherwise than by this new principle.

Fig. 5. Shows the two holes imaged through a small aperture which does not enable them to be separated.

Fig. 6. Shows the effect of reduced intensity: discrimination of two points (the holes are not resolved) is achieved.

The effect has been reproduced on microscopic objects as well and the experiments are being published elsewhere.

Arising from the experiments described above, it is suggested that a factor *I* for the intensity of the light should be included in the formula of resolution. The value of *I* cannot be given as a constant as it necessarily varies with the light source employed. In my experiments it had the rough value of 0·1, judging by the respective times of exposure necessary to record the effect.

My thanks are due to the Council of the Middlesex Hospital Medical School and to the Trustees of the Sir Halley Stewart Trust Fund for facilities which enabled this work to be carried out.

The Modern Centrifugal Pump as a Plankton Collector

THE elimination of the many sources of error encountered in some form or another when collecting plankton for quantitative work with silk nets is a problem that has been attacked many times. During the last fifty years, a number of workers, many of them with some measure of success, have from time to time used a pump and filter as a means of collecting a small, but quantitatively accurate sample, of plankton.

Encouraged by the obvious possibilities and advantages of this method, we have recently conducted experiments with a modern centrifugal pump. The experiments were made from the Research Ship *Explorer*, Fishery Board for Scotland, and the results have proved to be of great value and interest. We are preparing a paper on the subject in which the whole aspect of the problem of sampling is discussed, and the historical position of the plankton pump reviewed.

The experiments were conducted with a water meter included on the delivery side of the pump, and show how a comparatively large volume of water (two and a half cubic metres) was filtered in ten minutes with a two-inch pump. A three-inch machine would deal with almost double the volume (five cubic metres) in the same time, and it is a pump of this calibre that we suggest for general use.

Filtering can be done either by suspending the net in a tank of water to take up the force of heavy delivery, or direct on to the ship's deck. This latter method was used in our work and the results show that the plankton so collected is little, if at all, damaged in passing the impeller at 2,000 revolutions per minute. Even complicated chains of diatoms and delicate forms such as *Aglantha* remained whole, while some of the zooplankton forms were seen swimming actively in the filtered sample. The suction action is more than ample to take all forms of life, so that the collections are in no sense selective, and the results obtained indicate clearly the greater quantity of small forms, both of phyto- and zooplankton, as compared with the larger forms.

The suction hose, which is made in jointed lengths of 25 feet (8 metres), can be readily attached to a steel warp weighted with lead, and though in the experiments only two such lengths were used, they presented no difficulty in handling. As the pump was designed to overcome the frictional resistance in ten or more such sections, there would presumably be no more difficulty with 100 metres of pipe than with 12–15 metres. The joints are made with a quickly meshed screw thread, and are water-tight; and it was found that sections of much greater length than those used could be employed without difficulty.

This modern method of plankton pumping overcomes many obstacles familiar to the quantitative worker, and should be of widespread interest.

Symmetry of Symbols

THE application of the theory of symmetry to decorative designs is well known to students of crystallography and to mathematicians interested in the theory of groups. Text-books on design do not discuss these simple rules for the construction and classification of patterns, most likely because the subject up to the present has been treated only in the technical language of mathematics.

In preparing some articles which have as their purpose to explain the subject in a simpler form, I came across the following example which may be of more general interest. If we classify the letters of the alphabet according to their symmetry characteristics, we find the following five groups (in mathematical language they are the sub-groups of the symmetry group of the rectangle):

(I) F G J K L P Q R
(II) A M T U V W Y
(III) B C D E
(IV) N S Z
(V) H I O X

I. Those letters which have no real symmetry properties.

II. Those of which the left half is the mirror image of the right half.

III. Those of which the upper half is the mirror image of the lower half.

IV. Letters which can be rotated over half a circle without changing; they remain the same when the page is turned upside down.

V. Letters which have all the above characteristics combined.

What stands out in this classification is that the letters *N*, *S* and *Z* are together in one group. They are just the characters which are always written incorrectly by uneducated people It seems, therefore, that their type of rotation symmetry is slightly more difficult to grasp than the more common reflection symmetry. In this connexion it may be noted that many of the magic symbols used by ancient people possess such rotation symmetry over a half, a third or a quarter of a circle. This may perhaps help to understand why various primitive tribes independently have come to worship symbols like the swastika.

Points from Foregoing Letters

PROF. E. A. MILNE relates considerations recently advanced by Dirac with his own results, but concludes that there is no inference as to the creation of matter. The form of the differential relation connecting intervals for the $t \rightarrow \tau$ transformation is stated.

Under very feeble illumination the eye sees the visible spectrum in a uniformly grey colour (scotopic vision). It had been found that the maximum luminosity for *equal energy* is at 5000–5040 A., while the maximum absorption of the visual purple pigment in the eye is at 5100 A. Dr. H. J. A. Dartnall and C. F. Goodeve point out that if instead of comparing energies one compares equal *quantum intensities*, then the two maxima coincide. They consider this, and also further approximate calculations of the relative intensities of the light absorbed at different wave-lengths, to give support to the hypothesis that the primary process in scotopic vision is the absorption of light quanta by visual purple.

Recent experiments on the resistance of ferromagnetics show a sharper Curie point than the specific heat measurements. Prof. N. F. Mott and Dr. H. H. Potter state that this is to be expected, because the resistance depends on long-range order (domain of more than about 8,000 atoms) and the magnetic energy depends on the interaction of electronic spins at close range.

The percentage of glutamic and aspartic acids in Cotswold wool and in seagull quill has been determined by Dr. J. B. Speakman and F. Townend. They conclude that the results support the 'salt-linkage' theory developed by Speakman to account for the elastic properties of wool-fibres in solutions of varying acidity. According to that theory, the long peptide chains of the keratin molecule are bridged by linkages arising from the combination of the acid side-chains of aspartic and glutamic acids, with the basic side-chains of arginine, lysine and histidine.

A study of spore-forming bacilli by a vital staining technique leads Dr. L. A. Allen, Miss J. C. Appleby and J. Wolf to the conclusions: (1) that a single species of bacillus may show alternative methods of forming endospores, resulting in two different cell structures extraneous to the spore; (2) that the spores, after being released from the cells, are at first refractile, but may later (in old cultures) take up stain, revealing an internal structure which undergoes rearrangement during a considerable period of time.

The ovary and testis of young and embryonic rats and mice have been grown *in vitro* by P. N. Martinovitch. The ova developed and survived for three weeks, but at the end of a month the whole organ degenerated. Spermatogenesis was less successful, stopping at the pachytene phase during the chromosome reduction stage during meiosis.

Some of the changes taking place when the larvæ of the oyster settle and become 'spat' are described by H. A. Cole. Within ninety hours a considerable metamorphosis occurs while the diameter of the shell increases from 0·3 mm. to 0·6 mm. There is still a gap in the life-history of the oyster, since the next stage described is one in which the diameter of the shell has reached 1·2 mm.

It is suggested by Dr. J. R. Baker that the breeding seasons of equatorial birds may be controlled by changes in the intensity of visible and ultra-violet illumination.

Lieut.-Colonel L. M. Davies finds evidence that the Ranikot (Palæocene) Sea of India extended from Sind to the Tirah, and from the Tirah to Tibet. It was apparently isolated from the contemporary marine waters of Europe.

A. M. Hocart adduces a few examples and impressions of lineages which voluntarily isolate themselves for breeding purposes. These he considers give a clue to the segregation of species in Nature.

From recent observations by Rossi and Benedetti, H. J. Bhabha infers that the number of cosmic particles arising from a direction 30° west of the meridian is appreciably less than the number arriving vertically. These, he reasons, must be negatively charged, and if the radiation formulæ of quantum mechanics hold for the high energies involved, then either negative protons or some other negatively charged particles hitherto unknown must be assumed to be present in appreciable numbers in cosmic radiation.

An effect of increased resolving power of telescopes and microscopes produced by means of reduced light intensity in some diffraction experiments is described by Dr. K. B. Merling-Eisenberg.

S. G. Gibbons and J. H. Fraser have experimented with a modern high-speed centrifugal pump for collecting plankton, and find that even delicate organisms are undamaged. They claim that accuracy is obtained by this quantitative method of sampling.

Research Items

Milk-Drinking Habits of School Children

SPECIAL efforts have been made in Great Britain during the last few years to popularize milk consumption. The most important measure designed for this purpose was the so-called milk-in-schools scheme, by which milk is supplied free or at a reduced cost to children attending grant-aided schools. The object of this scheme was to encourage the milk-drinking habit in the younger generation, but little information exists regarding the habits of the children prior to its commencement. To remedy this defect, an inquiry was undertaken by the Hannah Dairy Research Institute, Kirkhill, Ayr, under the director, Dr. Norman Wright, the results of which have now been published by that Institute (Bulletin No. 7, 1936). The inquiry covered nearly 14,000 school children, about two thirds of whom were resident in Glasgow and one third in rural and urban districts of Ayrshire. The outstanding fact revealed by the inquiry is the small extent to which milk is normally drunk by children of school age. Of the 13,317 children investigated, more than one half did not drink milk at all and one third only took it once daily. Tea drinking, on the other hand, was almost universal, only five per cent of the children failed to take tea once, while fifty per cent took it three or more times in the day. Only twenty-five per cent of the children took porridge at breakfast. Of other drinks, coffee was rarely taken, and cocoa only by about seven per cent. Only seven per cent took water at dinner, but nearly half the children took it between meals or at supper.

Return of Swallows to their Nesting Sites

UP to the end of 1935, the number of swallows marked with numbered rings under the *British Birds* scheme was 34,243, the great majority being nestlings. The number recovered up to the middle of 1936 was 285, of which 24 were found abroad. A. W. Boyd and Dr. A. Landsborough Thomson (*British Birds*, 30, 278, Feb. 1937) have analysed the British returns, and find that adult swallows which have nested almost invariably return to the same place in subsequent summers, and often to the same nest. There is no record of an adult being recovered elsewhere in the breeding season, and there are records of pairs returning to a nest in more than one season. But young swallows very seldom return to the exact place where they were hatched, although many are found in the neighbourhood and within a few miles. A few were recovered so far away as 75–160 miles. A new feature which the analysis brings out is that soon after they are fledged, swallows tend to disperse from the nesting centre, previous to the setting in of true migration. This movement seems to take place in any direction, but since the observations are based upon the recovery of only 15 birds, confirmation is desirable.

Spawning of Black-headed Minnow

THE small North American cyprinoid, *Pimephales promelas*, known as the black-headed minnow, frequents areas where the bottom is covered with silt, and this leads to a peculiar spawning habit, described by L. R. Richardson (*Canadian Field-Naturalist*, 51, 1, Jan. 1937). To avoid the smothering of the eggs in mud, they are adhesive and are attached to the under surface of some substantial object lying clear of the river bed. The site is selected by the male minnow, which thereafter shepherds a female to the place, after having cut her out from a group of various species. Invariably the male swims below the female during the shepherding operation, chivvying, pushing and even snapping at her if she shows any sign of an attempt to escape. On the arrival of the pair beneath the nesting site, the male by steady pushing causes the female to rotate with gradually increasing speed in an anti-clockwise direction. At the same time he presses her into a sideways position, in which her belly comes in close contact with the under surface of the log, to which during or after a few seconds of extreme commotion the eggs are attached and fertilized. The female is then driven away by the male, who repeats the performance with another and perhaps a third female. No special attention is given to creating a protective structure about the eggs, but the male guards the egg-mass assiduously from the attacks of other individuals who would devour them.

The Brown Bat in Western North America

IN Canada, the United States and Lower California, and Mexico, five races of *Eptesicus fuscus* are recognizable. These conform to Bergmann's law, showing a progressive decrease in size from north to south, the greatest difference being 19 per cent in total length and 8–9 per cent in skull length (William L. Engels, *Amer. Midland Naturalist*, 17, 653; 1936). From the author's descriptions, it would also appear that richer coloration is more frequent in the moist coastal regions and that the inland race (*E. f. pallidus*) is distinguished by a much larger number of pale individuals.

Reactions of Nauplii to Light

THE nauplii of *Balanus amphitrite* and *Tetraclita squamosa* show remarkable reactions to light. Shuzo Ishida (*Sci. Papers Inst. Phys. and Chem. Res., Tokyo*, 30, No. 659) describes how in the same culture some move to the side of the beaker that is illuminated, and others, fewer in number, move to the opposite side; he terms these movements skotophobic and photophobic. By using a beam of light passing through a slit, the concentration becomes more marked since the illuminated area is limited, and by altering the direction of the beam it can be shown that the phenomenon is independent of geotropism. If the light is directed horizontally and half the beaker is screened vertically, the two types show an interesting circulation in opposite directions in the darkened half of the beaker.

Physiological Effects of Polyploidy in Tomatoes

DR. A. C. FABERGÉ has made a statistical investigation of the effects of tetraploidy in the tomato in two recent papers (*J. Genetics*, 33, No. 3) in which the effects on growth and size and variability are carefully analysed. It is well known that auto-tetraploids generally differ from their diploid parent in being larger and stouter in many of their parts and in having larger cells and nuclei, although the fruits appear to be always smaller. Dr. Fabergé finds, however, that tetraploid tomato plants contain no more substance and no more water than diploids, although $4n$ embryos are 30 per cent heavier than $2n$. This advantage is lost during germination. It is concluded that heterosis in the F_2 generation is due only to the greater initial weight, and is of the same magnitude in $2n$ and $4n$ plants. As regards variability, the results agree with those of Lindstrom in showing less variation in fruit-weight of $4n$ than of $2n$ plants. The same is true of the weight of whole plants, where the decreased variation is found to be due entirely to diminution in variability of the embryos. Possible causes of this surprising decrease in variation of tetraploids are discussed. In the fruits, the reduction of variability occurs not between different plants but between the fruits of the same plant. This appears to mean greater stability in the plants. It cannot be accounted for as a direct genetic effect of segregation, and the author suggests that doubling of the genes results in an increased probability of the action of quantitative factors, which is reflected in the greater physiological stability of the early meristems. In the terms of Timoféeff-Ressovsky, the penetrance and expressivity of quantitative genes may both be increased by an increase in their absolute number.

Vernalization of Garden Crops

THE process known as vernalization, in which the time of flowering can be controlled by treatment of the seed and seedling, seems to promise such beneficial results, that any practical contribution to the subject is of great interest. A short paper by Miss D. M. Turner and Mr. S. Burr (*Gard. Chron.*, Jan. 2, 1937) shows that tomato plants respond to vernalization. The most successful treatment seemed to be a chilling of the seed for twenty-four days previous to sowing, and the application of twelve days' continuous light to the young seedlings. Experimental results are on rather a small scale, but show that the yield of vernalized plants is both heavier and earlier than normal. *Calendulas* and peas apparently did not respond to the treatment.

Migmatites of Central Sweden

IN a recent memoir of the Sveriges Geologiska Undersökning (*Årsbok*, 30, No. 8, 88; 1936), Nils H. Magnusson describes his investigations of the veined gneisses of the iron-ore district of Kantorp in Sodermanland. The ores belong to the leptite formation, which consists largely of volcanic rocks and sediments and their metamorphosed equivalents. Transformation of these rocks to veined gneisses was brought about, during regional subsidence, by emanations and solutions which arose from deeper levels where palingenetic processes were active. The change begins with the appearance of pegmatitic spots and strings, and these gradually increase in proportion until pegmatitic veins dominate the rocks. It is noted that slates everywhere appear to be most readily pegmatized. Comparative studies of nineteen chemical analyses indicate that granitic emanations 'soaked' through the leptite complex with its iron-ores and limestones. The emanations were followed up by intrusive pegmatites and these, in turn, by granites. The latter are regarded as concentrated segregation products, the material of which came partly from below, and partly from the rocks now accessible at the surface. Reasons are given for rejecting the earlier view that the gneisses are products of magmatic differentiation during conditions of high tectonic pressure.

Earthquakes in New Zealand

DR. J. HENDERSON and Mr. R. C. Hayes have recently issued the report on New Zealand earthquakes for the year 1935 (Wellington, N.Z.,: *Dom. Obs. Bull.*, No. 116), a report prefaced by some general considerations on the earthquakes of the islands. During the century 1835–1934, sixty-nine destructive earthquakes were felt, of which forty-nine were of intensity 8 (Rossi-Forel scale) or semi-destructive, fourteen of intensity 9 and six of intensity 10. The regions visited most frequently by such earthquakes were the eastern and southern parts of the North Island and the northern part of the South Island. In the fiord region of the latter, sealers are said to have felt violent earthquakes in 1792, 1810 and 1826–27. Thus, although some parts of New Zealand have experienced no severe shocks during the last century, it does not follow that their immunity will continue. The year 1935 was a comparatively quiet one; there were no destructive earthquakes, and only one of intensity 7, the total number reported as felt being 150.

A New Mass-Spectrograph

IN part 7 of vol. 145, Section 2*A* of the *Sitzungsberichte* of the mathematical sciences division of the Vienna Academy of Sciences, Dr. Josef Mattauch, of the Physical Institute of the University, gives an account of the behaviour of the mass-spectrograph constructed by the Institute with financial help from the Academy and the Rockefeller Foundation on the lines laid down by himself and Dr. Herzog in the *Zeitschrift für Physik* (89; 1934). It depends on the power of a radial electrical field of mean radius a to render parallel a beam of positive rays diverging from a point $a/\sqrt{2}$ from the entrance plane of the field, whatever their velocities. If the parallel beam then enters a magnetic field at right angles, each mass component of it when bent through a right angle is focused on a plane through the point of entrance at 45° to the line of entry, and the distance of a line from the point of entry is proportional to the square root of the mass of each constituent. This system of double focusing has been generally adopted recently and gives excellent results. Dr. Mattauch finds a new isotope of strontium ^{84}Sr, new bands due to the dissociation of hydrocarbons, separates ^{14}N and ^{16}O from CH_2 and OH_2 and can resolve triplets.

Excitation of Phosphors in a Neon Discharge Tube

IN connexion with a note appearing in these columns under the above heading (NATURE, 139, 160; 1937), we are informed by Mr. C. C. Paterson, director of the Research Laboratories of the General Electric Company, Ltd., that a neon discharge tube in which a zinc silicate phosphor is excited by the discharge was patented by the G.E.C., Ltd. and H. G. Jenkins in May 1935, the patent becoming available to the public in November 1936. Such discharge tubes are at present being used commercially, while mercury discharge tubes with phosphors have been on the market in England for at least three years.

Science and Building Exhibition

THE Building Centre at 158 Bond Street, London, W.1, is an organization formed by architects and others associated with the industry, and supported by official bodies for the benefit of all engaged or interested in building. Its most prominent function is the formation and maintenance of a permanent but continually changing exhibition of building materials and equipment, where a technical staff is available to give unbiased information regarding these. Its range of usefulness to the industry and to the general public is extended by special temporary exhibitions held from time to time and by lectures on cognate subjects. In another direction, a very important contribution to the progress of building technique is being made by the work of the several research stations engaged on one or other aspect of this many sided subject and the Department of Scientific and Industrial Research has arranged at the Centre a special Science and Building Exhibition to remain open until March 25.

In relation to timber, the Forest Products Research Laboratory has been engaged on several lines of investigation. The attack of insects is under constant inquiry involving the study of their food supplies and digestive processes. Here, emphasis is given to the fact that the lyctus beetle is the most serious cause of loss in Great Britain. In relation to fungus attack, models of properly and improperly ventilated buildings show how the progressive destruction occasioned by dry-rot can be avoided, while in another section the quantitative relation of moisture content to shrinkage of timber is demonstrated. Two other lines of inquiry relate to the wearing qualities of wood and to the best cutting angles of woodworking tools. In the former, a comparative test has been devised whereby the relative value of each sample of wood can be stated, while the improvements obtained in economy and finish resulting from the latter investigation can only be adequately appreciated by inspection of the results.

Geological data regarding sites and resources of building stones, clay pits, limestones, etc., come within the province of the Geological Survey and Museum which, manifestly, can exhibit here only a few items from the store of maps, publications and other accumulated information available at its headquarters.

The pivot of this Exhibition may be said to be work of the Building Research Station, wholly directed as it is to the interests of the industry. Its exhibits are of a varied nature. Here are on view examples of tests on concretes, plasters, bituminous preparations, etc., and of the machinery devised for the testing and correct manipulation of the materials in use. Photographs are shown of the full-size tests conducted under fire conditions at the Elstree Fire Research Station.

The insistent problem of noise and its mitigation is dealt with at the National Physical Laboratory, and several models are exhibited to show how the use of suitable materials and methods of construction can eradicate its worst effects The conditions under which double walls and windows can be made effective, the right use of floating flooring to reduce impact noises, the elastic support of machinery and the application to walls of sound absorbent linings are demonstrated by means of models fitted with stethoscopes. On analogous lines, the work being done in connexion with illumination, wind pressures on structures and vibrations in roads and buildings is illustrated by means of diagrams and models.

In a series of photographic sequences, some aspects of the work of the Paint Research Station can be studied. A good paint requires to possess certain definite and distinct properties at different stages in its life—flow and 'brushability' during application, drying properties in the next stage, and elasticity, durability and appearance in its finished state. The photographs illustrate the tests applied at each stage and those also to which the raw materials are subjected. Of especial interest are those illustrating the electron diffraction camera used for ascertaining surface properties of pigments, the pattern obtained on a photographic negative and finally the actual atomic structure which can be deduced therefrom.

The Water Pollution Research Board and Chemical Research Laboratory have exhibits of fuller's earth in various conditions and of base-exchange and acid-exchange resins. These have been found to possess water-softening properties and the samples illustrate several stages in the processes of preparation. Apparatus used in determining the average concentration of lead in water for cooking and drinking is shown together with specimens illustrating the rate of the action of water on lead. Another activity represented is the purification of effluents from dairies and milk-products factories.

Domestic heating comes within the programme of the Fuel Research Station, the staff of which are showing samples of several fuels and are prepared to advise on this point with due respect to the national prejudice in favour of the open fire. The measurement of conditions in the domestic chimney is shown, and it is explained that so easily are these upset that special precautions are necessary as, for example, in ascertaining the amount of air passing up the chimney it is necessary to seal the room and admit air by one aperture in which the anemometer is placed.

A steel structure model illustrating the stages in the construction of multi-story flats is exhibited by the Iron and Steel Industrial Research Council and shows a number of alternative exterior treatments. Other exhibits and models illustrate the preparation and uses of 'foamed slag' for light-weight concrete. The British Non-Ferrous Metals Research Association is represented by tests on the behaviour of galvanizing and zinc coatings in domestic hot-water systems. The glass apparatus shown is used to test materials either in replacement of the corresponding glass part or by suspending a sample in the apparatus. The B.N.F. jet test, also exhibited, is designed to determine simply and rapidly the thickness of a metal coating, and an outline is given of the more important points emanating from the Association's research on the frost-bursting of water pipes.

Further opportunities of learning of these activities will be given in a number of lectures by members of research stations during the period of the exhibition.

Royal Botanical Gardens and Empire Botanists

By Sir Arthur Hill, K.C.M.G, F.R.S.

THE leading article in NATURE of January 9, on "National Museums of Natural History", discusses the relationship, "beyond the ordinary courtesies of friendship, which exists between these institutions". In the final paragraph, it is said: "We know of no such ties, and we wonder whether the interests of science in our Commonwealth of Nations would not be best served by attempting to develop such links. A free interchange of co-types could do much", and concludes, "But more is wanted, for the taxonomists in all [institutions] must have the same methods and ideas as to species in their work, and this can be secured by the periodical interchange of their staffs".

With regard to the Royal Botanic Gardens, Kew, which were specifically included with the "Museums" in the terms of reference of the Royal Commission on National Museums and Galleries appointed in July 1927, it seems desirable to direct attention to the fact that arrangements have been in operation for many years with other institutions and Governments, which are far more than "the ordinary courtesies of friendship" which, also, are of a very intimate nature with all other kindred institutions.

The Royal Botanic Gardens, Kew, being the headquarters of botanical work for the Empire, has built up in its herbarium and museums a vast collection of type specimens from all parts of the Empire, and the "Floras" of British India, Australia, South and Tropical Africa, etc., have been written at Kew. Kew, therefore, is the Mecca for our botanists from overseas, who must also pursue their studies among the historic specimens, especially from Australia, preserved in the British Museum (Natural History).

Sir Joseph Hooker, so long ago as 1882, realized the importance of establishing a close liaison between botanists working in India and those at the Royal Botanic Gardens, Kew, and on his proposal the Government of India appointed an Assistant for India to work in the Herbarium, and this post, paid by the Government of India, has been maintained since the year 1883. Several of the holders of the assistantship have formerly held Government botanical posts in India.

The Government of the Union of South Africa similarly maintains an Assistant for South Africa at Kew, but in this case a botanist on the staff of the Union Government is sent to work at Kew on the historical South African collections in the Kew Herbarium and returns to his duties in South Africa at the end of two or three years' service in the national herbarium. The salary of the Assistant for South Africa is paid by the Government of the Union of South Africa. This valuable arrangement came about as a result of a meeting of botanists of the Division of Botany held at Pretoria in 1918, in connexion with the establishment of the Botanical Survey of South Africa. At the moment, the South African Government has two officers working at Kew.

An Assistant for West Tropical Africa was appointed to Kew by the Governments of the West African Colonies in connexion with the preparation of "The Flora of West Tropical Africa". The assistant was appointed in 1909, but the post has now lapsed on the completion of the "Flora".

The proposal for the establishment of liaison officers between the Commonwealth of Australia and the Dominion of New Zealand and the Royal Botanic Gardens, Kew, was put forward by the Director of Kew in his report to the Governments of the Commonwealth and the Dominion after his visits to Australia and New Zealand in 1927–28, and received their approval. Nothing, however, resulted, for various reasons, and when the Third Imperial Botanical Conference was held in London in August 1935 the following resolution was passed:

"*Liaison Officers.*

"(1) This Conference commends to the Government of the Commonwealth of Australia the importance of maintaining close liaison in botanical matters with the Royal Botanic Gardens, Kew, and urges the Government to consider favourably the appointment of one of the younger Australian Systematic Botanists to work at Kew for a period of at least two years in making a critical examination of the historic Australian type-specimens at Kew and the British Museum and determining current collections made in the Commonwealth and sent over to Kew for critical examination.

"(2) It is further suggested that, at the expiry of his term of service, the officer appointed as Assistant for Australia should be replaced by another of the younger Australian Systematic Botanists."

Similar resolutions, appropriately worded, were passed with regard to New Zealand and Canada.

It is most gratifying to be able to record that the Commonwealth of Australia has now arranged to send over the Botanist from Perth, Western Australia, as its liaison officer to work for two years at Kew, who will be replaced at the end of the period by another botanist from the Commonwealth.

The resolution is also being considered favourably by the Dominion of Canada and by the Dominion of New Zealand. The Government of New Zealand hopes it may be able to send over in the near future a botanist to work at Kew, and it is expected that the Canadian authorities may eventually be able to send over an officer.

An interchange of officers has also been effected at Kew. A few years ago, one of the botanists on the staff of the Herbarium at Brisbane was sent over to Kew by the Queensland Government and a Kew Herbarium assistant was sent to Queensland to take his place, the two institutions paying the salaries of their officers. This exchange proved of the greatest possible value not only to the two institutions but also to the individuals themselves. The Australian botanist was able to study the historic types at Kew and the British Museum, while the Kew botanist had the opportunity of studying the flora of Queensland both in the field and in the Brisbane Herbarium, and also of getting into personal touch with all the botanists in the Commonwealth. Botanists from Kew have also been sent out to South Africa, Rhodesia and Malaya to study the flora, and botanists from all parts of the Empire are constant and welcome visitors at Kew.

It may be of interest to record that on the Gardens side the principle of exchange has for some time been in active operation, as we now exchange student gardeners with Germany, France, Italy, Sweden, Switzerland, Belgium, Canada, the United States of America and New Zealand, and other parts of the Empire when opportunity offers. The Kew student is sent out in exchange for one or two years, his place being taken by a student gardener from the botanic garden or other centre to which he has been sent. At the present time, twelve exchanges are in operation, much to the advantage of the men concerned and certainly to the advantage of Kew.

Wetting and Detergent Action

THE symposium on the "Scientific and Technical Aspects of Wetting and Detergency", held at the Imperial College of Science on February 19–20 under the auspices of the British Section of the International Society of Leather Trades Chemists, brought together a large company of scientific and technical workers for the discussion of nearly twenty interesting papers, which dealt with many of the known important points in these two problems, and suggested new points of view likely to prove important in future research.

The fundamental quantities determining whether a solid is, or is not, completely wetted by a liquid, are the surface tensions of the solid, and the liquid, and the amount of adhesion between the solid and the liquid. The impossibility, at present, of measuring the surface tension of solids is not such a serious difficulty in the scientific study of wetting as might be supposed, since the contact angle, which can be measured, is simply related to the surface tension of the liquid and the adhesion between solid and liquid, and is itself the immediately relevant quantity in most problems of wetting; and probably also in detergency.

C. G. Sumner described modifications in the 'plate' method for determining contact angles; N. K. Adam showed how contact angles can be determined on single textile fibres or thin wires visible under low powers of the microscope; and J. O. Cutter and C. W. Price reported a careful study of the method (originally due to Bartell and Osterhof) of measuring the adhesion tension and contact angles of liquids against solid powders, by determination of the pressure required to prevent the liquid penetrating into solid plugs of the powder, kept compact under high compression. This method, the only one available for the quantitative study of the wetting of fine powders, is not easy; it depends on careful attention to details of the apparatus and on the maintenance of a high pressure on the powder.

Probably the most important single industry dependent on the wetting properties of solid surfaces is that of mineral flotation; H. Freundlich dealt, in a short paper with a valuable bibliography, with the principal features of this process, including a discussion of the importance of contact angle, and of the surface films formed by the selective adsorption of the 'collectors' on the surface of the valuable minerals, which decrease their ease of wetting by the water and consequently cause them to stick to the air bubbles rising in the froth, and thus become collected at the surface. H. Martin described the very important applications of wetting agents in assisting the spread of insecticide solutions over the surface of leaves and fruit. He has taken particular account of the difference between the advancing and the receding contact angles, directing attention to which of the two is relevant for each practical problem; and he deserves gratitude for his timely protest against the pernicious and short-sighted practice of some manufacturers, in placing on the market, and expecting intelligent and chemically minded customers to use, or advisory officers to recommend, mixtures of unspecified and possibly inconstant composition bearing names suggestive of 'nostrums' rather than of scientifically manufactured and reliable products.

A paper by E. J. Daniels and D. J. Macnaughtan directed attention to some effects of surface impurities and inclusions in metals, on their ease of wetting by solders or by tin; this is a very important subject to which but little quantitative study appears to have been given. A. de Waele discussed the importance of wetting in the deflocculation and the plasticity of solid suspensions; and W. E. Wornum and G. A. Campbell dealt with the wetting problems of the paint industry, including the fundamental problem of the wetting of pigments by the liquid medium, and that of the surfaces to be painted by the finished paint or varnish. Wetting, it must be remembered, is not identical with deflocculation or dispersion; it is but one of the two main factors concerned. The other is the adhesion of the solid particles for each other, which must be overcome by the wetting liquid for the dispersion to be effective.

Detergency, which formed the subject of the second day's discussion, is a more complicated and perhaps more interesting problem. C. Robinson, in his introductory paper, discussed a theory due to N. K. Adam which places the emphasis in detergent action on the displacement of the grease from the solid surface, as comparatively large globules; the contact angle formed by the surface of separation between grease and aqueous detergent solutions, and the solid being cleaned, being the important measurable quantity determining the efficiency of detergent action. If this is correct, detergent action is essentially a preferential wetting of the solid surface by the detergent, instead of by the grease, and not, as has been occasionally held in the past, simply a wetting of the grease by the detergent, with consequent emulsification of the grease or other dirt. Surface and interfacial tensions, of course, enter into the problem, but neither alone is necessarily of predominating importance. Robinson considered also the problem of the removal of detached globules of grease from entanglement with the cloth; and described his measurements of the interfacial tension between oils and detergent solutions, which show some very remarkable effects of traces of polyvalent salts. G. S. Hartley discussed the power that solutions of soaps and paraffin chain colloidal electrolytes ('soap-like' substances) possess, of actually dissolving organic compounds which are insoluble in water. These substances, even in quite dilute solutions, have their long paraffin chain ions aggregated into 'ionic micelles', and Hartley suggests that the solvent power is due to the interior of these micelles closely resembling liquid paraffin, and having similar solvent properties; so that when such a substance as azobenzene, or cetyl alcohol, is caused to dissolve in a soap solution, it is not distributed evenly over the whole solution, but is all to be found in the interior of the ionic micelles. A discussion of the changes in vapour pressure, as the ionic micelles increase in size through taking up other organic substances, leads to the conclusion that they can increase only to a certain size before becoming unstable; hence the solvent power of a soap solution for organic substances insoluble in water is definite and limited, and there is an unstable region of sizes between the largest micelles which can exist, containing dissolved organic material, and the droplets of an emulsion stabilized by a monolayer of the soap-like material: these emulsions simulate stability, though they are not strictly stable in a thermodynamic sense. Whether such solvent action has any practical bearing on the problem of detergent action is not certain; but it is a most interesting and novel theory of solvent action in unusual circumstances. E. K. Rideal directed attention to the possibility that the molecules of detergent substances may penetrate and displace films of other substances adhering to a solid surface; that such penetration often occurs in monolayers at an air-water surface has been shown by J. H. Schulman and A. H. Hughes. An extension of v. Búzagh's work on the adhesion of solid particles to solid faces was also described, with particular reference to detergent solutions.

Space scarcely permits of an adequate notice of the important points in the chemical constitution of detergent and wetting agents, but papers by H. K. Dean, and by E. T. Williams, C. B. Brown and H. B. Oakley gave a general account of them. As a rule, the successful detergents have a long hydrocarbon chain attached to an ionizable, strongly acidic, end group; compounds of similar constitution but basic, yielding paraffin chain cations, may be good detergents but suffer from the practical difficulty that, being mutually precipitated by soaps, they cannot be utilized in conjunction with soaps. One case was mentioned, however, of a new detergent in which there is no ionized end group, but instead a polymerized glycerol derivative, partially esterified with fatty acids.

That wetting and detergent agents operate by forming surface films on the surface both of the solid and of the grease or other dirt to be removed is clear. Part of the discussion turned on the orientation of the molecules in these films. Though the proof is not complete, it appears probable that when the wetting of a greasy surface, that is, one externally composed mainly of paraffin groups, is assisted by a wetting agent, the hydrocarbon part of the molecule of the wetting agent lies flat on the surface; the observed increase in hydrophilic character can probably be accounted for by the presence of only one water-attracting group in the space on the surface occupied by a molecule of the wetting agent lying flat. Such observations as are available on the amount of adsorption of detergents by paraffin wax surfaces show it to be much less than that required to cover the surface with a monolayer oriented perpendicular to the surface, but of the right order for a complete layer of molecules lying flat. In cases where a soluble agent is required to diminish the ease of wetting of a solid surface, as with the collectors used in flotation, the molecules may be oriented perpendicular to the surface, but with the hydrophilic groups towards the solid; this is not yet, however, certain, as a considerable diminution of wetting could probably be attained even with the molecules lying flat. A rather interesting case of the deposition of a layer difficult to wet on glass was mentioned; substances such as cetyl trimethyl ammonium salts, with a long paraffin chain cation, cause (in dilute solution) clean glass to become greasy in appearance, probably through their hydrophilic ends being attracted to the glass, which thus acquires a paraffin-like exterior.

The papers presented will be published in a separate volume, shortly; and they constitute a valuable focusing of ideas on many very important, and not yet fully understood, industrial questions.

N. K. A.

Maiden Castle, Dorchester

A REPORT by Dr. Mortimer R. E. Wheeler on the results of three years' work on the hill-top site of Maiden Castle, Dorchester, on behalf of the Society of Antiquaries and the Dorset Archæological Society, was presented at a meeting of the former Society on February 25.

As originally planned, the excavation was intended to occupy three seasons. The third and last of these in the autumn of 1936 was prolonged until December 24. As, however, the site has proved of even more intense interest than was anticipated, providing evidence of signal importance in its bearing on the development of civilization in the south and south-west of Great Britain, it has been decided to extend the investigation for another season to enable supplementary excavations to be carried out next year.

Maiden Castle has always been impressive by its size alone; and its vast dimensions have borne witness to a capacity for economic and political organization, which it seemed difficult to credit to a population so primitive as the early inhabitants of Britain. Dr. Wheeler's excavations have shown that not only was the construction of a far more complex and imposing character than surface indication showed, but also that it embodies a complete picture of all known phases of urban life in Britain before the days of the building of Roman towns in the latter part of the first century; while the presumedly primitive character of early British culture is shown to be anything but in accord with the facts now revealed.

Dr. Wheeler distinguishes at least four major phases in the occupation of Maiden Castle. The first, belonging to the early neolithic, was a settlement at the eastern end of the mound which had long been covered over, and became known only by this excavation. It had been enclosed by at least three rings of entrenchment excavated in the chalk by deer-horn picks. A large section of this was uncovered in the excavations of the last season. From the contents it was evident that the settlers had been farmers, pasturing sheep and long-horned cattle, as well as practising agriculture. Their pottery showed that here in Wessex was a meeting place of the two strains of the neolithic in Britain, the western deriving from Brittany and the eastern from the Baltic. After a brief occupation by beaker folk from the Rhine, there followed a period extending over fifteen hundred years in which the site was abandoned.

Resettlement began in the eighth or seventh centuries; and by the fifth century B.C. settlers landing from north-east France had begun to raise the downland population to crowding point, necessitating organized defence behind the ramparts and entrenchments of the first Maiden Castle, concerning which recent excavation has revealed so much that is new in the elaborate limestone faced walls, the impressive double entrance, and the great ditch, 50 ft wide and 25 ft. deep. Then comes the great enclosed city, covering forty-five acres, with a population of upward of four thousand—a city, however, primarily of farmers and industrially self-supporting, with few imports. Finally, in the first century B.C., there was the last and most ambitious enlargement, a monument of civic dignity, when spreading ramparts and ditches and high stone walls were added, with a provision of twenty thousand sling stones at the gates to ward off attack—walls which were to be laid low and finally abandoned save for a brief period, when Roman Dorchester was built.

Science News a Century Ago

Lyell and his Views on Geology

ON March 7, 1837, Lyell wrote a long letter to Whewell regarding the criticism with which some of his views had met. "As we had some conversation the other day," he said, "touching the extent to which I carried my doctrine of 'Uniformity' in the 'Principles of Geology' I wish to refer you to the first edition of that work . . . in order to show you that certain passages were somewhat unfairly seized upon by the critic, and not duly considered with and interpreted by others and by the context generally of the first volume. . . .

"It was impossible, I think, for anyone to read my work, and not to perceive that my notion of uniformity in the existing causes of change always implied that they must for ever produce an endless variety of effects, both in the animate and inanimate world. . . .

"In the review in the *British Critic* . . . you stated three formidable theses which I had undertaken to defend, in order to hear out my theoretical views. . . . I am sure that none of the propositions can now seem to you extravagant and visionary. . . . I allude to, first the adequacy of known causes as parts of one continuous progression to produce mechanical effects resembling in kind and magnitude those which we have to account for; secondly, to changes of climate; thirdly, the changes from one set of animal and vegetable species to another. . . .

"I was taught by Buckland the catastrophical or paroxysmal theory, but before I wrote my first volume, I had come round, after considerable observation and reading, to the belief that a bias towards the opposite system was more philosophical."

Geology of Suffolk

AT a meeting of the Geological Society held on March 8, 1837, the Rev. W. B. Clarke concluded the reading of his paper on Suffolk. The substratum of the whole of Suffolk, Norfolk and Essex, he said, is chalk overlaid with clay, sand and crag. While the crag still lay beneath the sea a violent catastrophe broke up many of the secondary strata from the chalk to the lias inclusive, and the debris thus caused, together with numerous masses of ancient rocks, was spread by a rush of water, over the surface of the tertiary formations and the chalk, in some places to a depth of 400 feet, constituting the beds of drift, clay, etc., which occupy so great an area in Suffolk. Afterwards a series of shocks elevated the whole district until the crag attained the height of nearly 100 feet above sea-level.

Shillibeer's Voltaic Battery

WRITING from the Grammar School, Oundle, on March 9, 1837, to William Sturgeon, the Rev. John Shillibeer gave a "Description of a new arrangement of the Voltaic Battery and Pole Director". "In the course of the last winter," he said, "when I was preparing a few lectures on experimental philosophy for the amusement of my scholars, I was struck with the complicated arrangement of the voltaic battery, and the difficulty which frequently occurred from the number of connexions, to get all the wires into so perfect a contact as to ensure success to the experiment." To get over the difficulty he experienced, Mr. Shillibeer had devised a battery consisting of a copper trough divided into five compartments by copper partitions, the trough being filled with a solution of copper sulphate. Into the compartments dipped five plates of zinc the tops of which were soldered to a copper bar which was fixed to a wooden cover to the trough. In a groove in the wooden cover were two sliding terminals by which contact could be made with the copper or the zinc. By means of these terminals the direction of the current in a wire could be easily reversed. In concluding his description, Mr. Shillibeer said, "I cannot but feel gratified at the success which has hitherto attended the career of my little instrument; and very glad shall I be if it may lead to other and more important improvements in aid of a science which, let us hope, may be ultimately applied to purposes of solid benefit to all mankind." (*Sturgeon's Annals*, 1, 224.)

Airy's Observations at Cambridge Observatory

ON March 10, 1837, Airy communicated to the Royal Astronomical Society the "Results of the Observations of the Sun, Moon and Planets, made at Cambridge Observatory in the Years 1833, 1834 and 1835" During those three years, he said, the sun, moon and planets were observed on the meridian at Cambridge Observatory with the transit and mural circle, with as much regularity as the limited personal establishment of the institution permitted. The instruments with which the observations were made were not, he thought, surpassed by any in the world. The immediate results of observation were systematically compared with the places given by tables, and the apparent error of the tabular place in right ascension and north polar distance was given in the *Cambridge Observations*. The series of apparent errors thus found was, he believed, one of the most complete that had been formed from observations over the same period.

University Events

CAMBRIDGE.—D. H. Barron has been appointed University lecturer in the Department of Anatomy.

In a report of the Buildings Syndicate, it is recommended that the plans for a new School of Anatomy prepared by Mr. J. Murray Easton be approved, and that the Financial Board be authorized to accept a tender.

The degree of M.A. has been conferred on J. S. Baxter, D. V. Davies, M. T. Greig and W. R. M. Morton, University demonstrators in anatomy.

W. T. Astbury, lecturer in textile physics in the University of Leeds, has been approved for the degree of Sc.D.

The Sedgwick Prize offered every third year for the best essay on some subject in geology or kindred sciences and valued at about £90 has been divided equally between Dr. E. C. Bullard of Clare College and Dr. F. C. Phillips of Corpus Christi College.

Dr. J. Gray, University reader in experimental zoology, fellow of King's College, has been elected, as from October 1, 1937, to the professorship of zoology vacant owing to the retirement of Prof. J. Stanley Gardiner.

OXFORD.—Sir Arthur Salter (Independent) has been elected an M.P. for the University in succession to Lord Hugh Cecil, who resigned on his appointment as Provost of Eton. Sir Arthur, who is professor of political theory and institutions in the University, has been a member of the Economic Advisory Council since 1932.

In Convocation on February 27, the honorary degree of D.Sc. was conferred upon Prof. The Svedberg, director of the Physical Chemical Institute at Uppsala.

H. W. Thompson, St. John's College, has been appointed University demonstrator in chemistry for two years as from October 1, 1937.

Prof. N. V. Sidgwick has been re-appointed University reader in chemistry.

The following have been reappointed for four or five years as from October 1, 1937, as University demonstrators in their subjects: Dr. R. S. Creed and Dr. C. G. Douglas (physiology), T. C. Keeley (physics), Dr. R. L. Vollum (pathology), E. Whitley (biochemistry) and J. Z. Young (zoology).

Societies and Academies

London

Royal Society, February 25.

JULIA BELL and J. B. S. HALDANE: The linkage between the genes for colour-blindness and hæmophilia in man. Colour-blindness and hæmophilia are known to be sex-linked. The genes responsible for them should therefore be carried in the same chromosome, and exhibit partial linkage with one another. Six pedigrees are described in which both conditions are found. In three of these, the genes are located in the same chromosome, and are associated throughout the pedigree, all hæmophilics investigated being also colour-blind, and none of their non-hæmophilic brothers being colour-blind. In two pedigrees, the opposite condition holds, whilst one is doubtful, including two colour-blind brothers only one of whom is hæmophilic. This fact is attributed to crossing-over. A function $P\ (x, p)$ of the frequency x of crossing-over, and the frequency p of colour-blindness in the male population, is calculated, which represents the probability of the observed association. The probability that the association attributed to linkage is due to sampling is less than 4×10^{-6}. The frequency of crossing-over is as likely to be above as below 5 per cent. Further confirmation has been obtained for the view that hæmophilia originates by mutation.

D. E. LEA, R. B. HAINES and C. A. COULSON: The action of gamma rays on growing and on non-proliferating bacteria. Experiments are described on the lethal action of gamma radiations upon aqueous suspensions of *B. coli* and spores of *B. mesentericus*. Exponential survival curves are obtained, the mean lethal ionization dosages being approximately equal to those previously obtained for beta rays under conditions in which the rate of death was very much greater. Experiments upon *B. coli* in nutrient media are also described which suggest that the lethal action of the radiation proceeds independently of growth in the medium. Under certain conditions, abnormal *B. coli* in the form of long filaments have been obtained. A quantitative analysis of the results of viable counts, total counts, and length distribution measurements leads to the conclusion that the production of long forms is due to division being inhibited, while growth, in the sense of increase of volume, is unaffected.

Dublin

Royal Irish Academy, February 8.

L. B. SMYTH: Some observations on *Lophophyllum cyathophylliodes* Vaughan. This carboniferous coral was described by Vaughan under the generic name *Lithostrotion*. It is here transferred to *Lophophyllum*, and shown to be very variable. A young stage is described. The type is in Dublin.

J. SELWYN TURNER: The faunal succession in the carboniferous limestone near Cork. Lower Carboniferous zones from Z to D_1, inclusive, are identified in the limestone facies east of Cork city, and their fauna discussed, as a preliminary to a study of the Culm facies immediately to the west. At Little Island, the succession is best exposed, but observations were also made at Blackrock and Midleton.

Paris

Academy of Sciences, February 1 (*C.R.*, 204, 305–383).

EMILE BOREL: An elementary problem of strategy.

MAURICE GIGNOUX and FRANCK BOURDIER: The history of the ancient Rhone glacier at its exit from the Geneva basin.

CHARLES PISOT: The modulo 1 distribution of successive powers of the same number.

ROBERT FORTET: Probabilities in chains.

DANIEL DUGUÉ: An extension of the law of large numbers.

PAUL DELENS: Studies on the tetrahedron.

SERGE FINIKOFF: Series of Laplace for which the index surfaces of the same parity have their asymtotics in correspondence.

ANTOINE APPERT: The relations between Linfield spaces and complexes.

GEORGES KUREPA: The problem of Souslin and abstract spaces.

I. Privaloff: The general theory of polyharmonic functions.

Léopold Escande and Georges Sabathé: Researches on hydrometric velocity meters. Study of the errors introduced by the usual method of calibration.

Kentaro Yano: The unitary theory of fields proposed by M. Vranceanu.

Emile Sevin: Novæ and white dwarfs.

Raymond Grandmontagne: The photo-electric study of the colour of the night sky. Application of a recording photo-electric photometer, fitted with colour screens, to the study of the variations of brightness of the night sky. The distribution of energy differs from that of a black body, and shows a high proportion of red.

Mme. Irène Mihul and Constantin Mihul: The propagation of radio-electric signals between two points at a distance from each other.

Augustin Boutaric, Louis Ferré and Mme. Madeleine Roy: Spectro-photometric researches on the dilution and mixture of wines.

Salomon Rosenblum and Marcel Guillot: The possibility of the existence of equidistant energy levels in the nuclei of radioactive bodies.

P. Carré and H. Passedouet: The influence of the terminal group on the melting point of normal chain fatty compounds.

Jules Brüll: The influence of electrolytes on the hydration of some complex cobaltic compounds.

Maurice Curie: Phosphorescent glasses. The influence of crystallization. Experiments are described proving clearly the influence of crystallization on the duration of phosphorescence. Ordinary glass and zinc borate were used, the latter with additions of small proportions of manganese, lead, bismuth, samarium and uranium.

Jean Savard, Marc de Hemptinne and Paul Capron: The ionization potential of carbon monoxide. The number of critical points was so numerous that doubts arose as to the apparatus used; but a repetition of the work, with tantalum replacing copper, proved the correctness of the first experiments. The ionization potential of the molecule CO is given as 13·5 eV.

Arakel Tchakirian: The germanioxalates and zirconioxalates of quinine and strychnine.

Joseph Hoch: The action of organomagnesium compounds on the trialkylacetophenone oxims.

Paul Chovin: Researches on the Pechmann colouring matters. A method of synthesis allowing the preparation of colouring matters with unequal substituents.

Raymond Paul: The action of Raney nickel on some aldoxims.

Georges Dantlo: The esterification of Congo copal in the oil varnish industry.

Jean Cuvillier: Discovery of the nummulitic in the island of Shadwan (Red Sea).

René Perrin: Metamorphism and folding.

Lucien Plantefol: The respiratory oxidations: intrinsic and extrinsic oxidations.

Maurice Langeron: Statistical and mycological observations on human scald-head in Morocco.

J. Risbec: The crystal sac of *Nerita*.

Louis Fage: The apneumonic spiders.

Constantin Dawydoff: Some observations on the embryonic development of the madrepores.

Arthur Brunel: A new enzyme, allantoicase. Its presence in the animal kingdom. This enzyme is capable of splitting allantoic acid into two molecules of urea and one molecule of glyoxylic acid. Originally isolated in *Sterigmatocystis*, it is now shown to be present in the liver of *Raja punctata* and in the liver of frogs.

Maurice Doladilhe: The relations between alexine and the viscous protein of serum.

Moscow

Academy of Sciences (*C.R.*, 4, No. 6; 1936).

S. Soboleff: The algorithm of Schwarz in the theory of elasticity.

N. Košliakoff: Some infinite integrals.

B. Segal: Generalized Waring's problem in connexion with the estimation of trigonometrical sums.

G. Fichtenholz: Contribution to the theory of linear functions.

M. P. Želdak: Influence of cutting on the distribution of the first order strains in a cylinder.

P. M. Murzajev: Sericitization of pegmatites of the Gdov district, Leningrad region, and its genesis.

A. G. Eberzin: Miocene of south-east Transcaucasia.

G. G. Martinson: Distribution of sponge spiculæ in a bore hole of deep borings near the village Possolsk on the Baikal Sea.

G. Laemmlein: Twisted quartz.

A. E. Kriss: Anthocyanin in Actinomycetes.

V. Vasnecov: The caudal keels of fishes.

Vienna

Academy of Sciences, November 12.

Ernst Chwalla: A new type of solution in the theory of stability. The case of a symmetrically loaded rectangular framework having two joints is considered.

Otto Benndorf: Anthracene-1, 2-dicarboxylic acid anhydride.

November 19.

Jovan Jurišić: (1) Germination and morphology of the seeds of *Bryophyllum*. (2) Physiology of germination of Gesneriaceæ. Some species of Gesneriaceæ will germinate in the dark, provided the temperature lies within a certain range, while others will not germinate in any circumstances in the dark.

Rudolf Wagner: Existence of typical non-bracteolate blossoms of Rubiaceæ.

Herbert Schober and Heinrich Angenetter: Spark spectrum of radium emanation.

Lothar Koschmieder: Operational calculus with two variables, and the bilinear form of the Laguerre polynomial.

Franz E. Suess: Periplutonic and enorogenic regional metamorphosis. Regional metamorphs are divided into two classes according to whether the diffusion of material is brought about by temperature gradients or by tectonic displacements.

Julius Pia: Principal data from a stratigraphical study of the Prague Dolomites (south Tyrol).

Karl Strubecker: Circular quadratic complexes.

M. Pestemer and G. Schmidt: A new polarization photometer for the visual determination of differences of blackness, and its application to photographic spectrophotometry.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, March 8

Royal Geographical Society, at 8.30.—Prof. George Barbour: "The Tennessee Valley Project".

Tuesday, March 9

Royal Horticultural Society, at 3.30.—Prof. E. J. Salisbury, F.R.S.: "The Plant and its Water Supply" (Masters Memorial Lectures. Succeeding lecture on March 23).

Quekett Microscopical Club, at 7.45—(at 11 Chandos Street, Cavendish Square, W.1).—H. S. Sarson: "The Microscope and Distillation of Vinegar".*

Pharmaceutical Society, at 8.30.—Dr. W. H. Hatfield, F.R.S.: "The Uses of Stainless Steel for Pharmaceutical Apparatus".

Wednesday, March 10

Geological Society, at 5.30.—Dr. G. M. Lees and P. T. Cox: "The Geological Basis of the Present Search for Oil in Great Britain".

Institute of Welding, at 6.30—(at the Institution of Mechanical Engineers, Storey's Gate, S.W.1).—Dr. V. E. Pullin: "The X-ray Examination of Welds".

Royal Society of Arts, at 8 15.—Dr. C. S. Myers, F.R.S.: "Industrial Psychology and the Modern World".

Friday, March 12

Royal Society of Arts, at 4.30.—Dr. E. J. H. Mackay: "Excavations at Chanhu-daro".

Physical Society, at 5—(at the Imperial College of Science and Technology, South Kensington, London, S.W.7).—Annual General Meeting.

Royal Institution, at 9.—Sir Gerald P. Lenox-Conyngham, F.R.S.: "Monteserrat and the West Indian Volcanoes".

Institute of Metals, March 10 and 11, at 10 a.m.—Twenty-ninth Annual General Meeting to be held in the Hall of the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Assistant Lecturer in Electrical Engineering and Hydraulics in University College, Swansea—The Registrar (March 10).

Science Lecturer (chemistry, physics and mathematics) in the County Technical College, Worksop—The Principal (March 12)

Senior Physicist in the Wool Industries Research Association—The Secretary, Torridon, Headingley, Leeds, 6 (March 12).

Veterinary Bacteriologist in the Imperial Veterinary Research Institute, Muktesar, India—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (March 13).

Senior Scientific Officer in the Explosives Directorate, Research Department, Woolwich, S E 18—The Chief Superintendent (March 13).

Assistant (Grade III) (physics or engineering) in a War Department Establishment—The Secretary, Royal Engineer and Signals Board, Regent's Park Barracks, Albany Street, N.W.1 (March 13).

General Inspector of Agriculture in the Ministry of Agriculture for Northern Ireland—The Secretary, Civil Service Commission, Stormont, Belfast (March 15).

Principal of the Bihar Veterinary College, Patna—The Director, Veterinary Services, Bihar, Patna, India (March 31)

Lecturer in Mathematics in the West Ham Municipal College, Romford Road, Stratford, E 15—The Principal (April 3).

Cartographer in the Hydrographic Department of the Admiralty—The Secretary, Civil Service Commission, Burlington Gardens, W.1 (April 8)

Assistant Lecturer in Metallurgy in the University of Manchester—The Registrar (April 17)

Regius Professor of Chemistry in the University of Glasgow—The Private Secretary, Scottish Office, Whitehall, London, S W.1 (April 30).

Librarianship in Relation to Scientific Research

HUMAN nature being what it is, the continued existence of a collection of books presupposes the existence of a custodian whose primary instinct and duty is defence. So, no doubt, in the fifth or sixth century were the first librarians regarded; and so, of course, have the members of that profession to-day heavy responsibilities for the safety of priceless literary collections.

Not that all books are to be prized as storehouses of the mind; some indeed are "no good for reading", whilst others tell us "little that one need know, very much which it would be a positive mistake to believe". There are old libraries that resemble museums of antiquities, where the shelves are so many substitutes for glass cases; the bindings still a delight to the appreciative eye, and the leaves beckoning us to a near-by arm-chair for the pleasure of a dream in the remoter past. In tune with the atmosphere, we would call the venerable student in whose charge we enjoy these treasures by the name of 'library keeper', feeling the usual designation to be a little too businesslike and efficient for our mood. But there are also new libraries which repel or attract us, as may be, with the kaleidoscopic dust-covers of ephemeral fiction purporting to echo the delirium of a feverish modernity; where the keeper of the books cares nothing for their message (perhaps his sense of values is not so false after all) but counts his task well done when he replenishes his stock for fewer pence than his customers are willing to pay for their entertainment. He, too, is a 'librarian', if the title may still be held by a dealer in books, as it once was also by those who copied manuscripts and by their errors planted the seeds of so much perplexity and polemic in later generations. But to-day, if we exclude popular fiction, fewer books are read for pleasure—such is the pace of life and such the competition of other forms of enjoyment—and more for profit, so that our conception of librarianship has undergone a significant change; the custodian of books has come to be recognized for what he really is—a custodian of information. Perhaps the scientific library offers to him at once the most difficult task and the most fruitful opportunity of service in the nation's daily work.

Research, whether it be conceived in an academic spirit or planned to achieve some specific utilitarian purpose, needs for its development a basis of existing knowledge as wide and as deep as can be secured. Study of what is already known is the first step in discovering the unknown; and in that study the research worker needs help in increasing measure as the sources of his information become ever more numerous and heterogeneous. There was a time when the chemist, for example, was both expected and able to read most of the significant original papers in his subject; now he is fortunate if it is possible for him to keep abreast of part of it with the aid both of a voluminous special literature designed expressly for that purpose and of the extensive facilities provided by special libraries.

Yet a collection of books, journals, and pamphlets, while indeed the foundation, is not the only constituent of a scientific library as it is understood to-day. The service which such a library renders to students, investigators, and teachers alike depends for its efficiency on a human factor, the personality and the competence of the library staff; and for that reason, matters relating to their training are of some moment both to research workers and to students, particularly to those who may be fitted to serve their science better in a library than at a bench. Librarianship has already a valid claim to be ranked as a learned profession, the preparation for which is appropriately a concern of the universities. For example, the School of Librarianship at University College, London, is now in its eighteenth session, having been established by the Senate of the University of London on the basis of suggestions received from the Council of the Library Association, and opened in October, 1919. The School is "organised so as to give a systematic training on a broad basis to students who are already employed in libraries, record offices, or documentation centres, or who propose to adopt work of this kind as their profession."

The full-time course leading to the University of London diploma in librarianship occupies two years in the case of undergraduates (whose matriculation certificate must attest proficiency in Latin), or one year in the case of approved post-graduate students, whilst part-time students are required to devote from three to five years or two years, respectively, to the diploma studies, due account being taken also of practical experience in library administration. So much importance is attached to such experience that the diploma course includes a period of practical work to be carried out in selected libraries, a new arrangement which has already proved its value, and it is a condition of the award of the diploma that a substantial period of service in a library shall have been performed.

The University of London diploma is not, however, the only hall-mark which members of the profession may acquire. Fellowship of the Library Association is already recognized as indicating a very high degree of competence and experience, and the courses provided by the University of London School of Librarianship are equally available to persons desiring to take the intermediate and final examinations conducted by the Library Association. Here, therefore, are two avenues by which aspirants and those who have already commenced the journey may seek to demonstrate that they have reached that degree of competence which, combined with opportunity, will put them in possession, not of fame, but of the knowledge that they contribute significantly in advancing the world's work and culture. Perhaps when fuller recognition is accorded to the position which trained and experienced librarians occupy as 'key' men and women in unlocking the stores of accumulated knowledge for our instruction and delight; when both library authorities and senior members of the profession make greater use of such an institution as the School of Librarianship for the recruitment of their assistants, then an enhanced status will be associated with greater material rewards.

To this end, however, there must needs be co-operation between employers and teachers; and if the truth must be told—as indeed it should—there is here room for considerable improvement The director of the University of London School of Librarianship, Mr. J. D. Cowley, has recently made a substantial contribution. It is his responsibility to see that his students attain such a degree of familiarity with the principles of librarianship as will equip them to accept service under progressive authorities, and such practice in the application of those principles as will commend them to busy librarians who are thus spared much of the burden of instruction. He has therefore reorganized the syllabus in a manner which experience has led him to regard as desirable, and has devoted special attention to the practical aspects of the work. The new course, which is already in operation, provides lectures and examinations in languages, in English literary history, in cataloguing and classification, in administration (including local government organization and the administration of public, university, and special libraries), in bibliography and in palæography. It includes the period of supervised library experience to which reference has already been made, and makes provision for individual studies or research.

The hope may now be expressed that library authorities will, on their part, make a generous contribution to the further success of this scheme of professional training, helping it to serve more effectively not only the needs of the libraries but also the requirements of the reading public. They can do so, for example, by facilitating participation by junior members of their staffs, by regarding it as a principal source of supply of library officers, and by offering such salaries as will both attract the trained candidate and encourage the University of London to permit the School to expand, both in activities and in numbers, parallel with the demands which the profession of librarianship may make upon it in the interests of a community seeking culture, of a nation demanding progress, and of a world sorely needing that sympathy and understanding which fails where knowledge is lacking.

The Imperial Agricultural Research Institute, New Delhi

By Dr. W. Burns, Imperial Council of Agricultural Research

SINCE the time when Voelcker wrote his report "The Improvement of Indian Agriculture" in 1893, it has been recognized that agricultural progress in India must be based firmly on research. Accordingly, when Mr. Henry Phipps, an American philanthropist, came forward in 1901 with a splendid donation of £30,000 to be devoted to some project of public utility, if possible in the direction of scientific research, Lord Curzon, who was then Viceroy, decided to use the greater part of this donation for the construction of an agricultural research laboratory at Pusa. Pusa is in a rather out-of-the-way part of the province of Bihar, and the choice of site was not perhaps the happiest. The earthquake of January 1934, which did great damage to the Institute, brought up the question of rebuilding or shifting it. The second alternative won the day, and the result is the new Institute of Agricultural Research at New Delhi. But the old name Pusa has become very familiar, and those coiners of local place-names, the taxi and tonga drivers of Delhi, have already christened the new Institute the "Pusa College", while many scientific workers in India often refer to it as the "New Pusa".

The early days of Pusa saw the pioneer work of Leather in soil chemistry, of Butler in the realm of fungal diseases of plants, of the Howards in the production of new races of crops, especially wheat, and of Maxwell-Lefroy (whose name is written in the Book of Martyrs of science) in the cataloguing and combating of insect pests.

The Howards' wheats, particularly Pusa 4, Pusa 12 and Pusa 52, are now grown over six million acres in India, and some of the Pusa wheats have a vogue in Australia. Plant breeding for strictly economic ends and also the study of pure genetics have always figured largely on the programme of the Institute. Some useful hybrids between American and Indian tobaccos, wilt-resistant pigeon-pea strains, and better linseed types are some of the economic results, while the inheritance of characters in several important crops including linseed and chillies (*Capsicum*) has been the subject of important memoirs. It should be mentioned that the now world-famous Sugar Cane Research Station at Coimbatore in the Madras Presidency is a sub-station of the old Pusa and of the new Institute.

The site of the new Institute is within the limits of Imperial Delhi, and contains 476 acres of good agricultural land, plus 300 acres, of which part is pasture and part occupied by roads and buildings. About seventy miles from Delhi on the Grand Trunk Road (and also on the railway) is Karnal, where there is a farm that is now a sub-station of the Imperial Institute. Progress with the construction of the Institute was rapid. Lord Willingdon laid the foundation stone of the library on February 19, 1935. The library and laboratories were, in April 1936, ready for internal fittings and equipment. Work in these laboratories actually began in August 15, and the formal opening took place at the hands of His Excellency the Viceroy, the Marquis of Linlithgow, on November 7, as soon as possible after the Government of India came back to Delhi from Simla. Special references were made on that occasion to the late Sir Fazl-i-Husain (who had as Member for Education, Health and Lands been of the greatest help to the Institute) and the late Dr. F. J. F. Shaw, who was director of the Institute during the period of transfer and reconstruction. The total cost of the transfer, including the building of the new Institute and the acquisition and layout of the land, was Rs. 36 lakhs. The climate and soil of Delhi are suitable for growing a much greater range of crops than at Pusa. Part of the land will be cultivated under rainfall and the rest under irrigation water from the Jumna pumped through 12,000 feet of pipe line and open channels.

The New Delhi Institute naturally differs from that of Pusa in its buildings and layout. The Pusa laboratories were located in a central two-story building, divided up into sections for the various sciences and the library. At Delhi each science has its own separate single-story block, giving ample room for the present and opportunity for expansion in the future. The library is housed in a spacious central building with a clock tower. The Institute now possesses 80,000 volumes and is considered to have the biggest agricultural library in the East. It also receives every important periodical dealing with agriculture and its underlying sciences

The Botanical Section is housed in two blocks. The main one consists of a number of rooms equipped for advanced scientific work. The outbuildings are situated in an area of 50 acres laid out for plant breeding. New developments of this section are to be in the directions of plant physiology and cytology, while the plant breeding activities of the section will be maintained and intensified.

The Chemical Block, housing activities in soil science and agricultural chemistry, contains forty rooms fitted up for work in general analytical chemistry, micro-analysis, microbiology, soil physics, physical chemistry and plant chemistry. In addition, there are underground rooms where even temperatures can be maintained, laboratory workshops, a pot-culture house and lysimeters. A new feature of the Chemical Block is a laboratory for carrying out small investigations on the utility of agricultural products and to devise ways and means for the making of intermediate products. The need for this was recognized in 1921 by the Board of Agriculture in India.

In the Entomological Block are a main laboratory, a parasite laboratory and underground constant-temperature rooms. The rooms containing the collections have about 10,000 species represented by hundreds of thousands of specimens both pinned and in alcohol.

The Mycological Block has similarly rooms for use as laboratories, as constant-temperature rooms, as culture rooms and as herbaria, the last named containing a very valuable collection of fungi.

There is a group of buildings consisting of a dairy cattle byre with modern fittings, a veterinary dispensary, bull runs, sheds for sick animals and for segregation, and sheds for implements.

No mention of the Institute would be complete without a mention of what is a great attraction to visitors, namely, the famous Pusa pedigree Sahiwal herd. This is one of the finest herds of milch cattle in India. It has been in existence since 1904, when fourteen cows and one bull were purchased from the Punjab. It has gradually been selected from homebred stock with occasional fresh blood from outside. The average milk yield per cow per day has risen from 5 lb. in 1914 to 22 lb. in 1934. The bringing of this herd, numbering 172, from Pusa to Delhi was an achievement in itself, a special train being required, taking four days on the journey. There was no break in the recording of milk yields or of the routine of the herd during the transit, and the animals arrived at Delhi in first-class condition.

In addition to the research work of the Institute, there is also its educational activity. This takes the form of two-year postgraduate courses in which the student specializes in one or other of the subjects botany, chemistry, entomology or mycology, and in which the current research work of the Institute is the background of the teaching. Since the inception of this course in 1923, fifty-six students have passed out from the Institute, of which number forty-six have obtained employment either in provincial or State departments of agriculture or under schemes financed in whole or in part by the Imperial Council of Agricultural Research. There is also given a one-year course in farm management, and as occasion or need arises, short courses in special subjects such as the flue-curing of tobacco are arranged.

Lord Curzon, when laying the foundation stone of the original Pusa Institute, remarked that he would like to visit the place in fifty years time and see what it had grown into. He said, "Should I find Pusa the centre of a great organization, with ramifications extending to all parts of the Indian Continent, training a series of students who will devote their acquired knowledge to the practical pursuit of agriculture and able to point to the tangible results of successful scientific experiment, both in the quality of seeds and plants, in the destruction of pests, and in improvement of breeds of cattle ? That is the prospect that I should like to look forward to, and if it be at all realized then we may be assisting at a rather momentous childbirth to-day."

The now twice-born Institute faces the future with the means and the will to carry on to still completer realization this prophetic vision.

Chronological Problems in the Prehistory of North Africa

IMPORTANT questions relating to the antiquity of 'fossil' man in North Africa and to the dating and cultural affinities of the later stone age civilization of North Africa and the Sahara are debated by M. R. Vaufrey, of the Institut de Paléontologie humaine, Paris, in two recently published papers*.

In the first of these, M. Vaufrey has assembled and examined critically the evidence bearing on the age of the skeletal remains and artefacts found in the "escargotières" of Mechta el-Arbi, Tunisia. This midden site was discovered in 1907 ; but knowledge of its content is imperfect. Owing to the dispersal of the collections both of human remains and artefacts made by M. A. Débruge, to whom the exploration of the site was entrusted in 1913 and again in 1923, only one of the four skulls then found is now available, housed in the Institut de Paléontologie humaine. The remaining three, with an additional specimen, are represented by casts. There are also casts of a maxilla and a mandible, while there are two mandibles at Constantine, of which one probably belongs to the Mechta el-Arbi type. The Mechta el-Arbi type has also been recognized in the skeletons from the Ibero-Maurusian cave of Afalou bou Rhummel.

---

* Vaufrey, R , "L'Age des Hommes Fossiles de Mechta el-Arbi" *Bull Soc Historique et Géographique de la Région de Sétif* (1935) Vaufrey, R., "L'Age de l'Art rupestre nord-africain". *Bull Soc. Préhistorique Française*, **33**, No. 11.

The archæological material obtained from M. Débruge's investigations is also only imperfectly represented in collections, while the material obtained by the archæological mission of the Logan Museum (Beloit, Wis.) in 1926–27, though on a more extended scale, does not include a fully representative series of characteristic microliths owing to defects in the technique of excavation.

Nevertheless, the industry revealed by these investigations—an entirely microlithic industry—is not Capsian; and when the geometric microliths and the microburins, previously overlooked, are added, it conforms with the industries of Aïn Rhilane, Relilaï and a number of other sites of the same culture in the region of Sétif. These all belong to the upper Capsian—the middle Capsian being a purely hypothetical culture, which has never been described anywhere—or to a neolithic with Capsian tradition.

It follows that no greater antiquity than that of this culture can be ascribed to man of Mechta el-Arbi. In other words, Mechta el-Arbi man belongs to the Mesolithic age. Further, it also follows that Capsian man is still unknown. Other skeletal remains, such as those from Djebel Rocknia and Djebel Fartas, and the skeletons secured in 1890 by M. Pallary from caves in the neighbourhood of Oran, do not go back beyond the neolithic of Capsian tradition.

This neolithic of Capsian tradition marks the point when a neolithic culture with pottery, polished axes, querns for corn-grinding, and bifacial arrow-heads, broke in on an upper Capsian culture at the moment when the local industry was on the way to developing the arrow-head with transverse cutting edge. One result of the impact was the magnificent efflorescence of naturalistic rupestral art. This impact came from Egypt across Libya with the time-lag natural in all colonial development.

The age and affiliations of this culture, as found in association with the rupestral art in North Africa, are discussed further by M. Vaufrey in the second of the papers to which reference is made above. It opens with the critical examination of a statement made by M. M. Reygasse, which claimed a relatively high antiquity for certain rock engravings of the Sahara on the evidence of the discovery here for the first time of the spiral with figures of a fauna now extinct, or no longer found locally, such as, for example, the hippopotamus. M. Reygasse had argued further that this evidence showed that the spiral in the Sahara was independent of the Mediterranean, and that in the Hoggar and Tassili des Adjers it was older than the classical spiral of the eastern Mediterranean; while in addition it indicated that these engravings were much more ancient than the paintings showing the Garamantian vehicles.

M. Vaufrey compares the engravings of the Hoggar and Tassili des Adjers with those from Oued Chreaa in southern Oran, suggesting that these may well be the work of the same artists and belong to the same epoch. He maintains, however, that the extinction of the fauna, which is made the basis of the argument, may not have taken place at so remote a date as stated. It is frequently advanced on the evidence, *inter alia*, of the occurrence of a neolithic industry rich in green stone necklace beads in a cave in the central Sahara, that the desiccation of this region is of relatively recent date; while faunal evidence has been adduced in support of a neolithic pluvial phase in the Sahara extending from the middle of the sixth to the middle of the second millennium B.C.

It has been established by an investigation of a number of stations in Oran, some thirty in all, that the culture associated with the rock engravings is the neolithic with Capsian tradition. By the action of time and weather, this culture is not always represented in its entirety; the pottery, in particular, has usually disappeared. It is, however, better represented in more sheltered conditions, such as are found in the caves of El Arouia, north-north-east of Brézina, where a microlithic industry is associated with a class of pottery, in which the fundamental element is a type with pointed base, richly ornamented with incised decoration and frequently provided with lugs. There is also an abundance of polished axes of various kinds of stone, cylindrical or lenticular in section, as well as querns and mullers for grinding corn. In one of these caves was a naturalistic representation of one of the Equidæ and of a member of the ox family engraved on a stone. This industry was found in the north on the very borders of Oran, and from the evidence of the skeletons found by M. Pallary in 1890, its authors are known to have been of the type of the men of Mechta el-Arbi.

The pointed vases afford a new chronological element. They belong to the type found in the Gerzean culture of Negadeh in Upper Egypt of the predynastic epoch. In the same culture are found the earliest spirals, which appear on the painted ware with rounded base and with lugs, dating approximately from 4,000 B.C. Among a number of other indications of affiliation is the Libyan sheath, shown on figures at Fedjet el Khaïl and Kharrouba, which links with the Amratians, the predecessors of the Gerzeans, dating from 5,000–4,000 B.C., while an individual at Kharrouba holds a boomerang, which appears also among the Badarians of predynastic Egypt. Finally, the polished axes, the biface arrow-heads, and the harpoons and the fish-hooks of bone, which in North Africa extend as far as Mauretania, also appear in the earliest neolithic civilization of Egypt, the Tasian of the Fayum and Merimde, while the arrow-heads with transverse cutting-edge are found in the Amratian culture.

The neolithic with Capsian tradition of Oran is thus seen to comprise a number of features which derive from Egypt, but are found there as elements in cultures which succeed one another in a period extending from 6,000 to 4,000 B.C. In the Sahara these features appear more or less contemporaneously, as is shown not only by surface finds, but also on stratified sites. Hence the impression left by this neolithic culture of Capsian tradition is that it has been built up on a Capsian foundation by a succession of borrowings from the neolithic cultures of Egypt. It is a colonial culture, and like all such, is affected by a time-lag. Thus, for example, the head of a ruminant surmounted by a disk first appears in Egypt in the Amratian culture. The same figure, accompanied by bovides and ovides, appears in North Africa, but probably dating from the Middle Kingdom. Another example of the same kind is the painted representations of vehicles, which have been attributed variously to the Garamantes and other sources. The simplest explanation is that these paintings are the work of natives who had been in contact with Egypt under the New Empire, but certainly after the introduction of the horse and chariot into Egypt by the Hyksos. This would give a dating for the culture associated with these paintings, or of those representing the horse alone, such as that at Oued Chreaa, of 1,500–1,000 B.C.

While 3,500–4,000 B.C. would thus represent the extreme upward limit of dating for the neolithic culture of Capsian tradition, the gap which exists between this culture and the Mousterian or Aterian in southern Oran and probably throughout the whole of the Sahara, leads to the conclusion that no naturalistic engraving in the whole of this region is older than the neolithico-Capsian culture which is found in association with this North African school of art.

Natural Colour Eclipse Photography

THE first natural colour photograph of a total eclipse of the sun ever reproduced appears in the February issue of the *National Geographic Magazine*. The original photographs were taken on June 19, 1936, at Ak Bulak in Siberia, by Irvine C. Gardner, leader of the National Geographic Society and U.S. National Bureau of Standards Joint Eclipse Expedition

Dr. Gardner, in his very interesting article describing the general circumstances of the observations, states that six exposures on Dufay colour plates (of 1, 2, 4, 8, 16 and 8 seconds respectively) were made with a specially designed lens of 9 inches aperture and 19-feet focal length. The camera was fixed, being pointed directly at the eclipsed sun, and the plate holder moved to compensate for the solar motion. The solar image had a diameter of almost two inches. One of the photographs is reproduced in colour among the illustrations to the article.

It is perhaps scarcely fair to judge the original photographs by the reproduction, though there is no mention in the text of any differences between the original and the reproduction. The detail shown is, as one would expect, less than in the usual 'black and white' pictures, but all the main structure of the corona is visible, and the image extends to about a solar radius from the limb of the sun. The sky background is reproduced as a brownish-grey, rather than indigo, and the corona itself is distinctly pink, though it is pearly white to bluish to the eye The prominences show whitish to blue, and this seems to be nearer the truth than the common idea of a vivid scarlet.

The precise object of these photographs is not stated in the article, which is a popular account, but despite these defects as pictures corresponding to direct eye observation, these pioneer attempts at colour photography of eclipses are of enormous interest, for to the astronomers it matters little whether the photograph looks like the original. The important thing is whether there exists a one to one correspondence between the spectral composition of the radiation reaching us from the corona and prominences and the radiation transmitted by the photograph ; or, to be more exact, can the spectral intensity curve of the source be deduced from the spectral absorption curve of the photograph ?

Of course, such 'mosaic' processes as the Dufay colour, and nearly all natural colour processes, do not seek such a correspondence between source and image, but only that the image should closely resemble the source to the eye. As a given hue to the eye may be produced by more than one combination of homogeneous radiation, it does not follow that a colour photograph satisfactory to the eye would be equally satisfactory to the spectroscope, and so far no commercial process satisfies this latter test. But at least a 'mosaic' colour photograph can have the same sort of value that a set of ordinary photographs taken through filters has, and represents a coarse spectro-photometric survey. Dr. Gardner in his article does not state explicitly whether any steps were taken to make photometric measurements, but by implication something of the sort was contemplated. If it should prove practicable—and these first results of Dr. Gardner's hold high promise—to conduct even rather rough eclipse spectrophotometry in this fashion, then a new technique of great value will be at our disposal. It is too early to express any opinion on the possibilities of this method, but Dr Gardner is to be congratulated not only on his luck in obtaining clear skies at Ak Bulak, but also on his enterprise and his technical skill in securing these photographs.

Obituary Notices

Dr. W. Maldwyn Davies

BY the sudden and tragic death on February 17 of Dr. W. Maldwyn Davies of Bangor at the age of thirty-four years, entomology, and notably economic entomology, has suffered a grievous loss. Dr. Davies graduated with first-class honours at the University College of North Wales, Bangor, in 1925, and after two years at the Rothamsted Experimental Station he returned to the College in 1927 as adviser in agricultural zoology for North Wales, an appointment which comprised not only duties of a purely advisory character but also to no small extent investigation and research. For this post Davies, with his intimate knowledge of Welsh farmers and Welsh farming, was exceptionally well qualified, as evidenced by his work in connexion with the warble fly, in which science and practice were so happily combined.

Even more outstanding, however, was the research work that Davies was able to carry out in the brief period of ten years. Most notable perhaps was his contribution to our knowledge of the ecology of the aphis *Myzus persicæ* and its relationship to the spread of the virus diseases (mainly leaf-roll) of the potato. Starting from the discovery made by his colleagues, especially Dr. T. Whitehead, that in certain parts of North Wales potatoes could be grown from year to year without the introduction of fresh seed and without appreciable increase in the incidence of virus disease, Davies began a study of the aphis vectors of these diseases. By investigating the population of the aphides in the field, he was able to show that there is a significant difference in the numbers of aphides on farms where healthy seed potatoes could be grown and on those where they could not, a difference which in itself explained the varying incidence of virus disease. At the same time, the important discovery was made that the source of infestation each year was not overwintered eggs on various species of Rosaceæ, but aphides in the apterous stage overwintering on Brassicas, particularly Savoys, and it was concluded that winter Crucifers provide the main source of *M. persicæ* in spring.

The next step was to discover the factors that control the aphis population, and by a combination of laboratory and field work, Davies was able to show that the numbers of aphides in any district depend in part on the proximity of winter host plants but even more on the climatic conditions during the periods of migration. It was found that the aphides are unable to fly when the atmospheric humidity exceeds a certain maximum, owing to the effect of moisture on the wing membranes. It was also found that strong winds, instead of favouring migration, cause the insects to remain *in situ* on the host-plant. The potato-growing areas of North Wales could thus be differentiated on purely meteorological grounds into districts in which the transmission of virus disease would be facilitated by the presence of abundant vectors and those where it would not.

The last stage of the investigation, to establish whether the facts that held good in North Wales were also true of Great Britain as a whole, was already under way, and a visit to Scotland last year was to have been followed this year by a trip to Devon and Cornwall. This conclusion of the work must now be left to others, but Davies's contribution will remain a model of what such an investigation should be, and it is likely to rank as classic in its particular sphere.

Davies was not concerned only with the insects that attack plants, and his work upon the pests of farm animals, notably upon the sheep maggot flies, was of little less importance. At the instance of the Agricultural Research Council, he had recently had the co-operation of a biochemist (Dr. R. P. Hobson) in an investigation of these latter pests—a collaboration that had already produced valuable results and held out great promise of further success.

Davies's official work was thus primarily concerned with agricultural entomology, for which he had a special flair, but his interests nevertheless were not confined to this aspect of his subject. His earliest publications dealt with certain species of Collembola as pests of agricultural crops, and he was so attracted by these insects that he also found time to establish for himself a wide reputation as an authority upon them; many of the collections made by recent expeditions overseas passed through his hands for identification. He had in course of preparation a systematic key to the identification of the British species, which it is hoped is sufficiently advanced to render publication possible.

As a man, Davies was beloved by all who knew him, and he will be greatly missed by entomologists everywhere, and notably by his colleagues and friends in the agricultural services. J. C. F. F.

We regret to announce the following deaths:

Joseph Auclair, *correspondant* of the Section of Mechanics of the Paris Academy of Sciences.

Prof. Cyrus R. Crosby, professor of entomology in Cornell University, on January 11, aged fifty-eight years.

Prof. J. H. F. Douvillé, formerly professor of palæontology in the National School of Mines, Paris.

Sir Albert Kitson, C.M.G., C.B.E., director of the Geological Survey of the Gold Coast in 1913–30, on March 8, aged sixty-nine years.

Prof. C. J. Lewis, emeritus professor of public health in the University of Birmingham, on February 6.

Prof. F. P. F. Ransom, formerly professor of pharmacology in the University of London, on February 22, aged eighty-seven years.

News and Views

Sir Joseph Barcroft, C.B.E., F.R.S.

Sir Joseph Barcroft retires this year from the chair of physiology in Cambridge to which he succeeded on the death of Langley in 1925. Throughout an active life, Sir Joseph has played a prominent part in maintaining the high tradition of the Cambridge school of physiology. He has made many important contributions to knowledge, and has taught others to do the same, but his greatest contribution to physiology has been through his indirect influence on younger men. His enthusiasm, his good humour, his attractive style of writing and speaking, and his unusual gift for putting the results of profound thought into simple language, have inspired many with a love of physiology which has influenced them throughout their lives. As head of a large laboratory, he has found time to take a friendly interest in many different investigations without actively interfering with the natural development of the ideas of his colleagues.

Though he is not a medical man, much of Sir Joseph's work has been with human subjects, and much of it has had a dramatic quality that has made him widely famous. His early investigations were concerned mainly with the carriage of oxygen by blood, and with the chemical changes in organs such as the salivary glands and the kidneys which were found to use more oxygen during activity than during rest, and to liberate metabolites which controlled their blood supply. In order to study the gases in small samples of blood, or other tissues, he invented a differential manometer which is widely known as the Barcroft apparatus. For many years, he represented Cambridge against Oxford in favour of the view that the passage of gases through the epithelium of the alveoli of the lungs was a simple physical process and that, even under adverse conditions, the lungs could not take up oxygen unless the oxygen pressure in the air was greater than that in the blood. In support of this conclusion he led expeditions up high mountains, and exposed himself to low oxygen pressures for many days in a glass box in Cambridge. In more recent years he has shown, by striking experiments, that the spleen plays an important part in the circulation as a reservoir of blood, which is released in emergencies, and he has added much to our knowledge of the oxygen supply to the fœtus *in utero*, and other allied subjects.

Prof. E. D. Adrian, F.R.S.

Prof. E. D. Adrian, who succeeds Sir Joseph Barcroft to the Cambridge chair, has also spent all his scientific life in Cambridge, where he is now a Foulerton research professor of the Royal Society. Before the Great War he worked with Keith Lucas on the problems presented by the impulses in motor nerves. He then left Cambridge, obtained a medical qualification, and quickly showed that he could have been a very successful clinician. He was R.M.O. at the National Hospital, Queen Square, and during the War he had experience of the treatment of shell-shock. In 1919, he returned to Cambridge and started his well-known work on the physical basis of sensation. All knowledge depends on the brain's analysis of impulses arriving in sensory nerves. Adrian took advantage of the new methods for amplifying small electric currents and tapped the messages in the nerves. He has thus analysed the activity of sense organs in a way that was not previously possible. In recognition of this work he received, with Sir Charles Sherrington, a share of the Nobel prize for medicine in 1932. He is now called upon to spread his interests more widely than in the past, and to devote his clear brain and ready understanding to helping investigations in many branches of physiology.

Prof. M. N. Saha, F.R.S.

Prof. Meghnad Saha, who, as is recorded elsewhere in this issue, has been elected president for the current year of the National Institute of Sciences of India, is among the foremost of Indian physicists. He is chiefly known for his theory of stellar spectra, which he put forward in 1920 during a period of research with Prof. A. Fowler at the Imperial College of Science, London. In that theory, which began with a consideration of the solar spectrum and was afterwards extended to the spectra of the stars in general, Saha brought together the thermodynamical theory of ionization of atoms, at that time little known in England, and the observational indications of various degrees of ionization in stellar atmospheres found by Prof. Fowler and others. This formed the starting-point of a vigorous attack on the problems of stellar atmospheres, in which Profs. R. H. Fowler and E. A. Milne in England, and H. N Russell in America, have taken a prominent part. The result of this work has been not only a partial solution and the establishment of a definite viewpoint for the further examination of stellar atmospheric problems, but also the creation of a closer relationship between laboratory and astronomical physics, for in the light of Saha's theory certain atomic properties, for example, the duration of the excited state of an atom, can be determined from astronomical observation as well as, if not better than, from terrestrial experiments. Prof. Saha has also made other useful contributions to theoretical physics, and is the author of an imposing text-book on the subject.

British Chemical Industry and European Affairs

European affairs in relation to the chemical industry, and particularly to the British chemical industry, recently formed the subject of an address by Dr. H. Levinstein to the Institution of Chemical Engineers. If and when war comes it would, he said, be sudden and overwhelming, whilst industries unprepared for war could not be switched on to the requirements of war without great delay and immense cost. In 1914, war was not expected by the British chemical industry. Dr. Levinstein outlined some of the urgent requirements which the industry then had to face, and referred to some of the great deficiences, delays, and difficulties with which it had to contend. That it eventually surmounted these difficulties and removed these deficiencies is attested by military history, but, said Dr. Levinstein, "I have said enough to show the terrible delay, prolonging suffering and death, inevitable to going to war with our chemical industries as they were in 1914". On the other hand, "the German Government had the nucleus of a strongly centralised and organised industry for the chemical side of the production of munitions of war". The formation of Imperial Chemical Industries, Ltd., and the establishment of the Institution of Chemical Engineers are two developments of importance in the present organization of British chemical industry. "We may be thankful," he said, "for it is of great national importance, that the chemical industry is to-day more closely knit. . . . We are not so unprepared in all matters as may sometimes be thought. At least in the chemical industry we are stronger in every branch; more compact in structure, more complete in scope, with large units ably directed." The chemist has his responsibility, as a citizen, to help in removing the causes of war; but likewise his responsibility for ensuring an adequate defence against aggression is great. Dr. Levinstein has assured us that in Great Britain the chemical industry is not asleep.

Royal Commission for the Exhibition of 1851

In consequence of the Government's decision in 1935 to forgo any further contributions from the capital resources of the Royal Commission for the Exhibition of 1851 towards the cost of new buildings for the Science Museum, and owing to other factors that have lately tended to stabilize the Commissioners' income for some years to come, the Board of Management of the Commission has been able to set aside sufficient to provide for an additional annual scholarship of two or three years' duration. This will be used to extend to India the scheme of science research scholarships for overseas universities, each of which is of the annual value of £250–£280. To those who have watched the growth of post-graduate studies in India this decision has naturally given great satisfaction, and the allotment of even a single scholarship has been warmly appreciated by the Indian universities. Indian students have, of course, always been eligible for the coveted senior studentships, of which five are awarded each year by the Commissioners to advanced students of science nominated by universities in Great Britain. But until now they have had no chance to participate in the benefits of the overseas scholarships, which have been the means of training in the methods and technique of research and thus equipping for responsible positions in the scientific service of the Empire so much first-rate talent from the universities of Canada, Australia, New Zealand, South Africa and the Irish Free State. Moreover, these awards, of which eight have been made each year, provide a valuable link between research scholars of this country and the Dominions. From this point of view also the inclusion of India in the scheme is of considerable importance.

The Commissioners' research scholarships scheme, since it was first established in 1891, has, through its beneficiaries, achieved a noteworthy reputation. Of some six hundred past scholars, the majority now occupy positions of the highest rank in almost every branch of scientific activity. University life in Great Britain and the Dominions has been greatly enriched by the men and women trained under the auspices of the Commission. If rather more than half the scholars have distinguished themselves as principals, professors or lecturers in the academic world, the heads of many industrial laboratories and of Government technical establishments at home and abroad have also been recruited from the same source. No less than forty-one scholars have been elected to fellowship of the Royal Society and four of them have received Nobel prizes. This side of the Commissioners' work—and it is by no means the only side—is perhaps the most notable of their achievements since under the inspiring lead of the Prince Consort they set themselves their first task of developing as a great educational centre the property purchased at South Kensington with the proceeds of the Great Exhibition.

The Institute of Metals

Two important announcements were made by the president of the Institute of Metals, Mr. W. R. Barclay, at the annual general meeting on Wednesday, March 10. The first dealt with co-operation with two sister institutes. As a first step in a scheme of co-operation with the Iron and Steel Institute, members of each Institute can become members of the other without formality other than written application. Combined annual subscriptions and entrance fees have also been arranged. The present scheme of co-operation follows one recently completed by the two Institutes with the American Institute of Mining and Metallurgical Engineers whereby members, associates and student members of the British Institutes may, if under the age of thirty-three years, become junior foreign affiliates of the American Institute of Mining and Metallurgical Engineers on specially favourable terms, the arrangement being reciprocal in the case of members of the American Society. The president also announced that the Council had decided to issue an appeal for the creation of an Endowment Fund, to be invested for the support and extension of the work of the Institute. For the last few years the margin between income and expenditure in the annual accounts had been very narrow, and had afforded little or no opportunity to strengthen the Institute's financial reserves. Economies had been effected wherever possible, but these could not be extended without seriously curtailing the service the Institute renders to its members and to the industry in general. In the judgment of the Council the time had arrived when, on the basis of the record and achievements of the Institute, an appeal could and should be made to the non-ferrous metals industry for a substantial capital sum which it was hoped would appreciably lessen the anxiety constantly felt by the Council and its committees as to the financial future. He was glad to be able to announce that promises or actual contributions amounting to about £14,000 had already been received.

Prehistoric Cultures and Chronology in North Africa

THE most recent contribution of M. R. Vaufrey to discussion of a group of chronological and cultural problems in the archæology of North Africa, of which an account appears in another column of this issue of NATURE (see p. 432), is of more than local interest in its bearing on questions of wide import in the study of prehistoric civilizations. M. Vaufrey, the distinguished anthropologist who occupies a chair in the Institut de Paléontologie humaine in Paris, has explored extensively over a number of years among the prehistoric sites of North Africa, and his studies in the classification of the cultures and in the prehistory of that region are accorded the authority due no less to his meticulous precision as an investigator in the field than to his ability in the analysis of archæological evidence recorded by others. In his latest contributions to a subject upon which no one is thus better qualified than himself to speak, M. Vaufrey has two main objectives.

IN the first place, M. Vaufrey's aim is to determine with such precision as the case warrants the cultural association and dating thereby of the 'fossil' man of Mechta el-Arbi, a problem of no little moment in the history of the development of early types of 'modern' man in the Mediterranean area; and secondly, to determine the age which should be assigned to the characteristic art form of prehistoric North Africa, the rock engravings of varied forms of animal life in naturalistic style, a question long a matter of controversy among archæologists, of which the suggested solutions have ranged from the palæolithic to the Iron age or later. By his conclusions that this type of early man belongs to the Mesolithic age and even later, the early Neolithic, while the cultures with which he is associated, by correlation with the early civilizations of the Nile valley, can be fixed in terms of years at a period extending from the beginning of the fourth millennium, down to the middle or even the end of the second millennium B.C., M. Vaufrey arrives at a result which will be of the first importance when brought into relation with the study of mesolithic and early neolithic cultures throughout the whole range of cultural distributions in the ancient world.

Prehistoric Caves in Kent

A RECENT subsidence of earth at St. Mary Cray, Kent, has revealed the existence of a subterranean cavity, which, it is thought, may prove to be the entrance to a considerable system of caves, similar to that at Chislehurst, two and a half miles away to the south, where thirty miles of galleries have been explored since the caves were rediscovered in 1902. Marks of deer-horn picks, still clearly visible, show where prehistoric man cut away the chalk. Although it will not be possible to attempt to explore the caves at St. Mary Cray until the fallen subsoil has been removed, entrance to two chambers, it is stated in *The Times* of March 4, has been made by Mr. Gibson-Cowan and Mr. Geoffrey Edwards, who found them to be about five feet high by thirty feet long. Probing with a pole ten feet long at the end of the farther chamber failed to encounter obstructing chalk, and it may be concluded, therefore, that they extend in this direction, while the existence of an earlier subsidence a quarter of a mile away, suggests that there may be a system of connected caves of considerable extent. The Chislehurst caves have produced few archæological relics; but as an Elizabethan villa has been shown to have had direct access to the caves by means of a stair, and the caves were used as refuges, disturbance must have been considerable. At St. Mary Cray, there is no evidence of occupation, at least since Roman times. It is possible, therefore, that they may serve the needs of the archæologist to better effect, and it may be, throw further light on the prehistoric excavators of the chalk, to whose activities the dene holes, notably near Croydon, bear witness. Exploration of the newly discovered caves will begin as soon as the subsided clay has been removed and the roof of one of the chambers has been supplied with the necessary shoring.

Modern Developments in Broadcasting

IN a paper read before the Institution of Civil Engineers on February 16, Sir Noel Ashbridge traced briefly the growth of broadcasting transmission and television, and referred to some of the recent developments arising from the researches carried out by the B.B.C. The paper dealt at some length with the design of studios and the effect of size, shape and materials upon their acoustic properties. The advantages of the ribbon microphone over its predecessors were referred to, and the principal methods of sound recording were described. Improvements in the design of transmitting stations are broadly covered by schemes for economizing the power required for producing a given radiation output, and by the use of high vertical aerials, which tend to concentrate the radiation in the horizontal plane so as to give the most efficient service area. Sir Noel remarked on the difficulty of accommodating all the European broadcasting stations within the available wave-length band, and described the expedient of sharing wave-lengths between two or more transmitting stations by synchronizing their carrier waves. Next, a reference was made to the Empire broadcasting service, and the reasons which necessitated the use of short waves for this purpose were outlined. As a result of research carried out on the design of short-wave aerials to give the most efficient radiation, a considerable improvement is to be expected in overseas reception when the new short-wave transmitters of the B.B.C. are brought into operation in the near future. The paper concluded with a brief description of the methods and technique being employed for the transmissions from the London Television Station on ultra-short waves. The results of field strength surveys round London were given, and reference was made to the effect of interference from motor-cars and electrical apparatus.

Ultra-Short Wave Broadcasting

THE broadcasting service from the Alexandra Palace television station has already illustrated the suitability of ultra-short waves as a medium for the transmission not only of high-definition pictures but also of speech and music of very high quality. The latter achievement arises from the fact that in the ultra-short wave-band, the permissible band width available for the modulation frequencies is many times that obtainable amidst the present congested conditions in the medium and long-wave broadcasting bands. It is rather natural to suggest, therefore, that more use might be made of the ultra-short wave-lengths for high-fidelity sound broadcasting. This matter was referred to in a note in *The Times* of February 18, in which it was pointed out that this aspect has been under consideration by the B.B.C. for some time past. Indeed, experiments were carried out some years ago with a transmitter installed on the roof of Broadcasting House and operated on a wave-length of six metres. Further experiments are being conducted, but it is stated that no plans have yet been made for the development of a public service on these lines. A large-scale extension of the ultra-short wave broadcasting of sound would be complicated by at least two factors. First is the fact that the B.B.C. is not the only user of the band of wave-lengths below ten metres, for some other national services already have vested interests there. Secondly, there is the difficult problem of interference from the ignition systems of motor-cars, which cause very unpleasant noises in neighbouring receivers working on ultra-short waves. It would seem to be unlikely that broadcasting on these wave-lengths will become really popular until the fitting of suppression devices to such ignition systems is made compulsory.

Radio-Elements as Research Tools

IN a lecture to the Society of Chemical Industry on March 1, Prof. F. A. Paneth discussed "Radio-Elements in Chemical and Biological Research". Owing to the extreme sensitivity of electrometric methods it is possible to detect radio-elements in much smaller concentrations than any other chemical substances; and as they are isotopic with ordinary elements we can in many investigations substitute a radio-element for its inactive isotope. Such use of 'radio-elements' as indicators is frequently of great help if the behaviour of an element in very small concentration has to be investigated Perhaps of even greater importance is a slightly different application. By mixing a fraction of a stable element with its radioactive isotope we can differentiate this fraction from the rest of the element, and then study the exchange of atoms of identical chemical properties. It is especially this use of 'indicated atoms' which opens the door to otherwise insoluble problems. Since the discovery of artificial radio-elements, almost every chemical element can be obtained in the form of its radioactive isotope, and the use of radio-elements as indicators has been greatly extended.

AMONG the problems to the solution of which radio-elements have contributed are the determination of the solubility of very slightly soluble compounds, the preparation of the volatile hydride of bismuth, the study of the permeability to air of almost completely airtight gas-mask fabrics, of the formation of alloys at low temperatures, the rate of solution of exceedingly thin films, and electro-deposition from extremely dilute solutions. With the help of 'indicated atoms' the diffusion of lead into lead, the determination of the surface of adsorbing crystalline powders, the exchange of atoms of one and the same kind in chemical reactions have been studied for the first time. The active isotopes of carbon, phosphorus, sodium, calcium and other elements of special importance in biology make it possible to investigate the metabolism of these atoms. The use of radio-elements as indicators is steadily increasing and it is to be expected that in future many chemical, physical and biological laboratories will avail themselves of the great possibilities offered by this method in the study of an infinite variety of problems.

Bird Preservation

THE British Section of the International Committee for Bird Preservation, of which Dr. Percy Lowe is chairman and Mr. D. Seth-Smith treasurer, is appealing for support. It is governed by a committee of sixteen drawn from the Royal Society, the Royal Society of Edinburgh, the Zoological Society of London, the British Ornithologists' Union, the Royal Society for the Protection of Birds, the National Trust, the Society for the Promotion of Nature Reserves and the Society for the Preservation of the Fauna of the Empire. The British Section is not only representative of bird protection interests in Great Britain but, in addition, is in direct communication with similar sections of twenty-six nations. Its work is essentially international in character and deals with problems which can only be solved by scientific and even 'political' work on a very wide front. These include the drafting of a new international convention for the protection of European birds; the destruction of birds by waste oil at sea; the protection of the quail, which is caught in thousands during the breeding season for export to European countries; the conditions under which live birds are transported by sea; and an inquiry into the status of the Anatidæ. This latter, which is regarded as vitally important by scientific workers and sportsmen throughout Europe, includes investigations ranging from the conditions obtaining in northern breeding grounds to the diminution of *Zostera marina*. Of paramount importance is a scheme for ringing duck in order to trace their lines of migration. To carry out this work adequately it is essential that the income of the British Section should be greatly increased. All persons interested are therefore invited to become either patrons at three guineas or associates at 10*s*. 6*d*. a year. Subscriptions should be sent to the Secretary, Miss Phyllis Barclay-Smith, British Section, I.C.B.P., c/o Zoological Society of London, Regent's Park, N.W.8.

Town Planning and Decentralization

THE relationship of man to his work and his environment was explored from various aspects at a conference held by the Garden Cities and Town Planning Association, at the Housing Centre, 13 Suffolk Street, S.W.1, on February 27. Dr. Norman MacFayden, former medical officer of health for Letchworth, showed statistically that the satellite town has proved its great value from the health point of view; his comparative figures for tuberculosis and pneumonia were particularly convincing. He stressed the close relationship between man and Nature which is taken into account in the planning of garden cities, but which the modern congested cities, for example, London, Manchester, Glasgow, cannot provide. The case for the satellite town was further strengthened by papers presented by G. L. Pepler, Colin Clarke and Dr. D. H. Smith. Dr. Smith gave a full account of the uncontrolled location of industries in the Lea Valley on the outskirts of London, and pointed out that in the great majority of cases there was no reason why the factories should not have been located at a greater distance, within satellite towns. He listed a number of problems: noise, traffic congestion, traffic control, vulnerability in war time, journeys to work, as well as health and æsthetic aspects which should be further investigated and could be solved by decentralization. Mr. Colin Clarke estimated the change in the proportion of workers employed in manufacturing industries for 'export' and as compared with local industries and services, and concluded that the increase in the latter, following upon an increased standard of living, will also favour decentralization during the coming decades.

Electricity Supply in Great Britain

ON March 3, in reply to a question by Sir M. Macdonald, Mr. Hore-Belisha, the Minister of Transport, said that his Majesty's Government has decided to adopt in principle the recommendations of the McGowan Committee for a reorganization of electricity supply of the country. A few minor modifications would be added, which he understood would be generally acceptable. In the report it is stated that any attempt to carry through a scheme of reorganization on a voluntary basis would fail, and legislation must confer definite and adequate compulsory powers. It is also stated that schemes of reorganization should make provision for the possibility of ultimate public ownership of all undertakings, including those not at present subject to purchase by the local authorities. Complete standardization of systems and voltages and of methods of charge, as well as amalgamation of a large number of small undertakings into a smaller number of large ones will be necessary. As a result of such reorganization, considerable further development of rural areas should be possible. The scheme recommended by the McGowan Committee should result in a general, though necessarily gradual, reduction in costs. It rejects nationalization as a solution of the distribution problem, at least in the present stage of the evolution of the industry. It prefers to proceed by the gradual method of overhaul and consolidation and a more efficient grouping of existing undertakings. In a report published last December by P E P (Political and Economic Planning, 16 Queen Anne's Gate, S.W.1), the problem is summed up by saying that the public expects that the supply industry will hasten towards a future where the residential consumer, the farmer and the industrialist will have full freedom to use electricity to the greatest advantage. This will obviously take several years.

Nationalism and Use of Land

IN an article on "Nationalism and Land Utilisation in Britain" in the *Geographical Review* of January, Dr. Dudley Stamp directs attention to some of the results of a nationalistic policy in agriculture. Agricultural returns for 1935 and 1936 show an increase in arable acreage and in the total area of improved land, due to protective tariffs, marketing subsidy and, above all, the wheat quota. These schemes lead to excessive specialization in the commodities thus favoured, and they may, by bringing hill slopes under the plough, do more harm than good by the promotion of soil erosion. Again, the general application of, say the wheat quota, throughout the country overlooks the fact that though very little of the country is definitely outside the limits of wheat cultivation, a great part of it is not favourable, and would be harmed by constant soil disturbance. Another important consideration that is overlooked is the very small area of really first-class soils suitable for intensive arable farming such as market gardening, and yet near London and other great towns, where these products are most required, building is allowed to spread regardless of the value of the soil. Furthermore, in the 'reconditioning' of the land, or regrading to a fuller use, it is necessary to supplement the economic standard of judgment, cost per unit, by a standard of nutritional value, and pay more attention to meat and dairy products, poultry farming, and fruit and vegetable production.

Experiments in Resuscitation

A REPORT by the Soviet Union Year Book Press Service relates that ten years ago Dr. Sergei Briukhonenko carried out the following experiment. He removed the head of a dog and attached to it an apparatus which he called the autojector for artificial circulation of the blood, with the result that the severed head was kept alive for six months, reacting to all stimuli. Some years later, Dr. Briukhonenko succeeded in resuscitating a whole animal. A dog had its thorax opened and the action of the heart stopped. Death set in, but the animal was revived by the autojector. In 1936 the Institute of Experimental Physiology and Therapy was created to assist Dr. Briukhonenko in his researches. The result has been that not only has resuscitation been effected so long as half an hour after death, but also life has been maintained so that dogs which were put to death in various ways in August and September 1936 and then resuscitated are still alive and in excellent condition.

Lambeth Degrees

AN interesting note on these degrees, by Dr. Cecil Wall, appears in the "Brompton Hospital Reports", vol. 5, 1936. The power to grant such doctorates in any faculty was given to the Archbishop of Canterbury in 1534 through the Act of Supremacy and Succession. A number of degrees in medicine and science, apart from other faculties, have thus been conferred. The Lambeth doctorates were usually conferred for eminent service on those who were unable to conform with the university regulations for internal degrees. Among the men of science who received such degrees on the dates mentioned were Robert Hooke, physicist and secretary of the Royal Society (1691), John Woodward, geologist (1695), and Peter Dent, botanist (1678).

Books on Industrial Management

THE Management Library (23, Bloomsbury Square, W.C.1) has issued a list of forty-seven recommended books on industrial organization and management arranged under such headings as scientific management, finance and accounting, production management, distribution, advertising, commercial and industrial training. The Library contains some further three thousand volumes, and detailed lists, constituting a catalogue, are available free on (1) general management; (2) production; (3) accounting and company secretary; (4) distribution, including retailing; (5) rationalization; (6) psychology; (7) economics; (8) industrial biographies. Short critical reviews are published to keep members up to date as well as an annual cumulative subject-indexed guide to book selection.

Astronomical Society of the Pacific

AT the annual meeting of the Astronomical Society of the Pacific held in San Francisco on January 30, it was announced that the Catherine Wolfe Bruce Gold Medal for 1937 has been awarded to Prof. Ejnar Hartzsprung, director of the University Observatory, Leyden, Holland. In announcing the award, the president of the Society for 1936, Prof. A. O. Leuschner, gave an account of Dr. Hertzsprung's outstanding contributions to astronomy. Announcement has been made by the Director, Dr. W. H. Wright, of provision for an annual appointment to be known as the Alexander F. Morrison Memorial research associateship in the Lick Observatory. Appointments to the research associateship will be made by the regents of the University of California. "The appointee shall be an astronomer, or an authority on some other subject intimately related to astronomy, of wide and admirable repute by virtue of contributions of great value which he has made to the science of astronomy. The holder of the Research Associateship will reside at Mount Hamilton as a guest member of the staff for a certain portion of a year as would be agreed upon." Prof. Hertzsprung has accepted an invitation to be the first visitor under the new foundation.

A New Comet

A COMET of about the seventh magnitude was discovered during the evening of February 27 at the position R.A. $0^h\ 35 \cdot 3^m$: Dec. 19° 22′ N. (at $18^h\ 25 \cdot 1^m$ U.T.). It was first reported to the Central Bureau at Copenhagen by Prof. A. Wilk of the Cracow Observatory, Poland, but apparently the comet was discovered almost simultaneously by observers elsewhere. From observations made since February 27 at Warsaw, Meudon, Copenhagen, in England and elsewhere, two preliminary orbits have been computed, but the one given by Whipple and Cunningham of the Harvard College Observatory appears to fit the observations the better. The elements of this orbit give the date of perihelion as 1937 Feb 21·73 U.T. and perihelion distance as 0·620 ($\omega = 32° \ 9'$: $\Omega = 57° \ 3'$: $i = 25° \ 57'$). Thus during the present week the comet is receding from the sun, but its distance from the earth is decreasing. In consequence its brightness has remained nearly stationary, though possibly it may reach a maximum about March 13 or 14; although the comet is not a naked-eye object, it should be within the range of binoculars. On February 27, the comet was near the borders of the constellations of Pisces and Andromeda; since then it has been traversing the latter constellation, being near the bright star β Andromedæ in the evening of March 10; the comet's path, continued through Perseus, will have entered Cassiopeia on March 24. In Great Britain the comet has been photographed two or three times by Mr. G. F. Kellaway of Yeovil, Somerset; a short tail to the nucleus is shown on the photographs. Dr. A. C. D. Crommelin thinks that it is worth while to examine the possibility of identity of the present comet with that of the comets of 1532 and 1661.

Announcements

Honorary membership of the Royal Asiatic Society has been conferred upon Prof. Jules Bloch, of the University of Paris, Prof. Carl Brockelmann, of the University of Breslau, and Prof. J. Ph. Vogel, of the University of Leyden, in recognition of their eminent services to Oriental research.

The Royal Society of Edinburgh has awarded the Gunning Victoria Jubilee Prize for the period 1932–36 to Prof. C. G. Darwin, master of Christ's College, Cambridge, formerly Tait professor of natural philosophy in the University of Edinburgh, for his distinguished contributions in mathematical physics; and the Makdougall-Brisbane Prize for the period 1934–36 to Dr. E. M. Anderson, formerly of H.M. Geological Survey (Scotland), for his paper "The Dynamics of the Formation of Cone-sheets, Ring-dykes, and Caldron-subsidences", published in the Society's *Proceedings* within the period of the award.

According to *Science and Culture*, at the annual meeting of the National Institute of Sciences of India held at Hyderabad on January 5, the following officers were elected for the current year: *President*, Prof. M. N. Saha; *Vice-Presidents*, Prof. S. S. Bhatnagar and Lieut-Colonel R. N. Chopra; *Foreign Secretary*, Prof. B. Sahni; *Secretaries*, Prof. S. P. Agharkar and Dr. A. M. Heron; *Treasurer*, Dr. S. L. Hora.

At the annual general meeting of the Geological Society of London held on February 19, the following officers were elected for 1937–38: *President*, Prof. O. T. Jones; *Vice-presidents*, Prof. W. T. Gordon, Mr. J. F. N. Green, Prof. W. J. Pugh, and Prof. H. H. Swinnerton; *Secretaries*, Dr. L. Hawkes and Prof. W. B. R. King; *Foreign Secretary*, Sir Arthur Smith Woodward; *Treasurer*, Mr. F. N. Ashcroft.

At the annual general meeting of the Society of Public Analysts and Other Analytical Chemists held on March 5 the following officers were elected for 1937: *President*, G. Roche Lynch; *Vice-Presidents*, A. L. Bacharach, H. E. Cox, B. S. Evans, A. R. Tankard, J. F. Tocher; *Hon. Treasurer*, E. B. Hughes; *Hon. Secretary*, Lewis Eynon.

The International Commission of Zoological Nomenclature has elected Mr. Francis Fleming to be secretary in succession to Dr. C. W. Stiles, who has resigned on account of ill-health. The Secretary's address is: British Museum (Natural History), Cromwell Road, London, S.W.7.

Beginning on April 1, the Victoria and Albert Museum, including the India Museum, and also the Science Museum, South Kensington, are to remain open on Thursdays, Fridays and Saturdays until 8 p.m. At present the Museums close at 6 p.m. The Museums will remain open until 8 o'clock on the Monday bank holidays at Easter, Whitsun and August.

The University of Lille has accepted the 15,000 francs awarded to Dr. Cloudesley Brereton for his book on France by the Commission du Tourisme, for a prize to be awarded in alternate years for the best essay on the works of M. Izoulet, of the College of France, and on Mr. Branford's work, "Eros and Psyche" (University of London Press).

Jean Chazy has been elected a member of the Section of Astronomy of the Paris Academy of Sciences in succession to the late M. Hamy.

Prof. Heinrich Gloël, of Wetzlau, has been awarded the Goethe Medal for Art and Science.

Prof. P. Rivet, professor of anthropology in the Museum of Natural History, Paris, has been created a Commander of the Legion of Honour.

Prof. L. van Itallie, of Leyden, recently delivered an address before the French Society of Clinical Biology, after which he was awarded the Pasteur Medal.

Prof. Karl Beurlen, professor of geology and palæontology at Kiel, Prof. Albert Dietrich, professor of pathology at Tübingen, and Prof. Hans Seger, director of the Silesian Museum for Art and Antiquities, Breslau, have been elected members of the Imperial Leopold Caroline German Academy at Halle.

The Rockefeller Foundation has made a grant of 10,000 dollars for the investigation of filterable viruses under the direction of Dr. George P. Berry, professor of bacteriology and associate professor of medicine at the University of Rochester (U.S.A.), and one of 6,400 dollars for the study of the biological effects of heat by Dr. Stafford L. Warren, associate professor of medicine and radiology.

NATURE

SUPPLEMENT

No. 3515 SATURDAY, MARCH 13, 1937 Vol. 139

Science and Industry in the Eighteenth Century

Matthew Boulton
By H. W. Dickinson. Pp. xiv+218+15 plates. (Cambridge: At the University Press, 1937.) 10*s.* 6*d.* net.

ADVENTITIOUS insertion of obituary anecdotes in lectures and text-books has done much to create a pardonable prejudice against the [illegible]istorical approach to science. This is regrettable [illegible]wo reasons. The first is that some of the most [illegible] hypotheses have been built with a scaffold-[illegible]logy and metaphor the significance of [illegible]ried in a forgotten social context. [illegible]at the history of science, which is [illegible]f the positive constructive achieve-[illegible]uman reason, is largely neglected by [illegible]ns. Hence the social culture of the [illegible]ury does little to reinforce confidence [illegible]er of rational co-operation. Of late, [illegible]en a new orientation, signalized in [illegible] by the publication of Hessen's much-[illegible]y, Prof. Woolf's book on seventeenth [illegible]ce and technology, a new appreciation of Hooke's work, Crowther's "British Scientists of the Nineteenth Century", and a series of memoirs in the *Economic History Journal*. The most notable of the last-named are: one by Lennard, who has edited the "Heads and Enquiries" into the prosperity of British agriculture issued in the first decade of its existence by the Royal Society, and an article on the relations of science to early English capitalism by Prof. G. N. Clark.

In one way or another, these authors show a new interest in the growth of science as a department of social history. They are less concerned with the admitted capabilities and domestic idiosyncracies of the principal actors than with the social circumstances which enlisted their interests, provided them with problems for inquiry and supplied the means of solving them. The influence of technical, ideological and institutional changes on the momentum of scientific research and the impact of new discoveries on the progress of technology, social habits and social organization are now being recognized as the professional business of the historian of science. Inevitably this makes more exacting demands than the serial obituary method. It also creates the need for a *genre* of social history which has not yet been written.

The history of science may therefore prove to be a substantial bridge between naturalistic and humanistic studies, and the beginnings of a truly scientific humanism. Many years must elapse before an authoritative work ranging over so wide a field as Whetham's "History of Science" can be undertaken with due regard to the fact that science is a social institution and that scientific workers are members of a social group. Meanwhile, the more modest task of compiling case histories concerning organizations and persons with a pivotal relation to the application of science in social life can do much to provide the necessary materials. Matthew Boulton is pre-eminently such a person, and Mr. Dickinson deserves our gratitude for a work of ripe scholarship and rich entertainment. Such is the new biography which he has given us.

It is a curious circumstance that much more has been written about the relations of science and industry during the seventeenth and nineteenth than during the eighteenth centuries. The outburst of zeal for the prosecution of scientific inquiry in Stuart times was predominantly related to navigation and the beginnings of capitalist farming. London as the centre of English mercantilism was also the centre of a highly localized culture directly or indirectly related to mercantilist policy. During the subsequent struggle between the chartered monopolies and local manufacturing interests, London forfeited its pre-eminence. Edinburgh, with the brilliant coterie which included Black, Francis Home, Playfair, Hutton and Roebuck; Birmingham, with its Lunar Society of Boulton, Erasmus Darwin, Wedgwood, Priestley and Watt; Manchester, with Henry, Dalton and James Watt, junior; and Bristol, with Beddoes and Davy, were foci of flourishing local activity in scientific research during a period when the official organs of education fully justified the pessimism finally ventilated in Babbage's tract on the "Decline of Science in England". As yet, none of them has been exhaustively explored for material relevant to the task of the historian of science.

For Birmingham the materials are most accessible. Not the least valuable part of Mr. Dickinson's biography are the opening chapters which trace its industrial development and personnel through what Nef ("Rise of the British Coal Industry") calls the first industrial revolution of Stuart times. Already in 1538, wrote Leland, "a great part of the Towne is maintained by Smithes who have their Iron and Sea cole out of Staffordshire". There the pottery industry, already flourishing in the seventeenth century, was destined to provide an early market for the partnership of Boulton with Watt. The propinquity of the Potteries proved important in more ways than one. Mr. Dickinson mentions the fact that Boulton's project to adapt the Newcomen engine for pumping water from the tail race to feed a mill-wheel "had been already adopted by other persons". From a recent article by Thomas in the *Transactions of the Ceramic Society*, it appears that it was first done by the master potter John Turner a few years before Boulton discussed the possibility with Benjamin Franklin. Extracts from this correspondence establish an interesting link between the Philadelphia Academy, the Lunar Society and the Edinburgh centre. Small, a Scots physician who had been professor of natural philosophy in the College of Williamsburg, Virginia, returned to his native country with an introduction from Franklin to Boulton, and was directly responsible for introducing Watt to the latter.

The close relations between the Edinburgh centre and the leaders of the Industrial Revolution in the eighteenth century would repay further search. The references to Black in the letters of Watt and the Wedgwood-Playfair correspondence included in the biographies of Smiles bear eloquent testimony to the unity of Scottish theory and English practice at this period. Mr. Dickinson gives us some relevant information about the business relations between Boulton and Roebuck (of sulphuric acid fame) and between Boulton and Keir, another Scots chemist, who set up an alkali factory about the same time as the introduction of the Leblanc process. The part which Birmingham played in the rise of chemical industry (in the modern sense) is not so widely known as its place in the history of power production. Watt himself was instrumental in getting bleaching powder produced on a commercial scale, and Murdoch's installation in the Soho factory started the commercial production of coal gas. The craze for 'bone china' sponsored by Spode at this period created a commercial demand for bone ash and possibly nursed into being the match industry.

James Watt, junior, who represented his father's interests in Manchester, is a direct link between the groups which respectively included Priestley and Dalton. How the new social need for theoretical guidance made it possible for them to pursue "knowledge for its own sake" has been sufficiently documented by Smiles. In the initial stages of the Industrial Revolution, chemistry was the science in greatest demand. Such was the social context in which chemical science was re-established on new theoretical foundations. It is a curious obliquity of vision to isolate the individual passion for truth from the historical circumstances which decide whether it is encouraged and along what paths it is guided.

Mr. Dickinson notes in his preface that no separate biography of Boulton has appeared since Smiles wrote "Lives of the Engineers: Boulton and Watt" in 1865. It will be recalled that t[illegible] same author also wrote a life of Wedgwood. [illegible] Dickinson, who has already given us a [illegible] volume on Watt, would perform a gr[illegible] if he added new materials to our kn[illegible] social milieu in which Priestley w[illegible] panion volume on the Prince of Po[illegible] a welcome supplement. If a less sp[illegible] than Boulton, Wedgwood, who co[illegible] Boulton in providing financial backin[illegible] was a more focal personality in re[illegible] scientific renaissance of their time. [illegible] interests in pyrometry and geology, [illegible] chemistry, closely followed the techn[illegible] the Potteries and ranged over a muc[illegible] There is a mine of new material at t[illegible] the University of London in a recent [illegible] dissertation by Thomas on the rise of [illegible] shire industry.

Mr. Dickinson writes with enthu[illegible] merges into hero worship, and pa[illegible] Men such as Boulton, Wedgwood a[illegible] were the finest flower of a stage in so[illegible] when the *entrepreneur* still discharge[illegible] function in organizing prosperity and [illegible] the advancement of knowledge w[illegible] prosperity possible. The book is bea[illegible] illustrated with photographs of Boulton's prod[illegible] and mechanical diagrams. A feature which wil[illegible] commend it to students of economic history is the account of Boulton's relations with the Mint and the technical problems of coining in his time.

L. H.

Place-Names and their Study

(1) The Place-Names of Warwickshire
By J. E. B. Gover, A. Mawer and F. M. Stenton, in collaboration with F. T. S. Houghton. (English Place-Name Society, Vol. 13.) Pp. li+409. (Cambridge: At the University Press, 1936.) 21*s*. net.

(2) The Concise Oxford Dictionary of English Place-Names
By Eilert Ekwall. Pp. xlviii+520. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 15*s*. net.

(1) THE volumes issued by the English Place-Name Society steadily increase in interest as the series lengthens. This is due in no small degree to the added skill which comes from experience in dealing with the material. The Warwickshire volume, it is true, is only the second excursion of the Society into the Midlands; but apart from the adventure of new country, the names on the whole have not the intrinsic attraction which is attached, for example, to the wealth of evidence relating to paganism in the volumes for Surrey and Essex, to name the most recent issues, nor can Warwickshire make a contribution equal in interest to that of the latter of these two counties in the study of early Saxon settlement.

The earliest reference to the name of the county is in the Anglo-Saxon Chronicle under the year 1016 in the form Waerincwicsir. It appears in a later reference as Waeringscir. That the area of the present county is not a homogeneous unit is indicated by the character and distribution of the place-names, which preserve the distinction, political indeed, but determined by geographical conditions, affecting the character of settlement, rather than by any adjustment of racial boundaries.

So long ago as the seventeenth century the famous Warwickshire antiquary, Dugdale, noted the distinction between the northern and southern areas of the county. This is to be seen in the fact that in the north, where are such names as Birmingham, Tamworth, Polesworth, settlement is of the hamlet type, whereas in the south there are large villages with the open field system, as around Oxhill and Tysoe. The settlements of the north are typical forest clearings. The Hwicce advancing into the south from the west, and founding their settlements along the valley of the Avon, found themselves on the edge of the great forest of Arden, which joins on practically continuously to the great Royal forests of Feckenham, Morfe and Cannock. Here they halted; and this northern area was left to the settlement of the Mercians, who advanced along the valley of the Nene. For them the forest determined that the form of their settlement should be the isolated farm and hamlet and not the village with its open field. The boundaries of the ancient sees of Worcester and Lichfield preserve the older civil distinction. In the Lichfield diocese, Mortimoe, near Radway, has been traced to an earlier form Mercna Mere, "the boundary of the Mercians".

Among the references to early conditions preserved in place-names one of the most interesting is Tysoe. This, the "hoe" or "hob" of Tiw, is the first reference to be encountered in the survey of the name of the old English pagan god of war. It clearly associates his worship with a spur of the Cotswolds, which forms the south-eastern boundary of the Vale of the Red Horse. Although no early reference to the latter name has been found, as the editors point out, it affords strong probability that the hills bordering the vale were once marked with a symbol appropriate to the war god. In any event, the name proves that the Hwicce were still sturdy pagans when they reached this point of their advance.

References to either Britons or Norse are not numerous. Walcots and Bretford are among indications of the former, while the latter appear only on the eastern boundary, as, for example, in the name Kirby, being confined here, as elsewhere, to the eastern side of Watling Street. Celtic derivations appear most numerously, as usual, in connexion with rivers and streams as in Anker, Avon, Arrow, Itchen and Leam.

Memory of the exploitation of the salt mines of Droitwich lingers in the name Salt Street, which appears three times on the line leading in the direction of Stratford.

Neither Norman-French nor purely French names have left a strong mark on the county. Among the latter is Beaudesert, the name of a castle in France, and among field names occur such as "le commun champ" and "le novel gardin".

(2) The volumes of the English Place-Name Society, while satisfying the need of general interest, are planned with the requirements of scholarship in view; but they have not yet covered the ground, nor will they do so for some

time to come. In the meantime Dr. Ekwall's admirable "Concise Oxford Dictionary of English Place-Names" is available as a source of information and instruction, both for those counties with which the Society has still to deal, and to meet the needs of those who are interested in the subject without being specifically students in this or related branches of research. Here the place-names are set out in alphabetical order, each with an indication of its component elements and derivation. Although the list is not complete, it is sufficiently full to meet all but an exceptional test. As a corrective of the uninstructed enthusiasm of the place-name mythologist, Dr. Ekwall provides a preface in which he has set out the main principles to be followed in the study of place-names, and indicates the principal provinces of study—archæology, local and national, and social and racial history—in which it has proved an invaluable aid to research.

Accidents

Accidents and their Prevention
By Dr. H. M. Vernon. Pp. ix + 336. (Cambridge: At the University Press, 1936.) 15*s.* net.

INCREASING attention is being paid to industrial accidents and their prevention throughout the world; the question has indeed become one of scientific study and inquiry into the proneness and incidence of accidents in relation to personal qualities and environmental conditions.

In Britain, in all good factories, the immediate treatment of minor injuries is being encouraged so as to minimize the time lost by absence from work. Systematic inquiry is being made into the cause of all accidents, and it is customary to hold a regular 'court-martial' into the more serious ones. Careful statistics are kept and exchanged with other firms, and trade associations give special attention to problems which are common to their industry. The Home Office is at all times helpful in a variety of ways.

Accidents are in the main due to human error, but it is the duty of the employer to remove so far as possible all temptations to err. The subject in some of its aspects occupied a session at last year's Chemical Engineering Congress, when the interesting fact was brought out that in Germany the after-care of the injured falls on the firm, whereas in Great Britain it falls largely on the insurance company.

In the main, in large establishments a great deal is being done, though this must be regarded only as a step towards even better conditions: in small factories and working establishments, there is doubtless still much to do, and it is these which require legislative stimulus to make them realize their responsibilities. The slogan "Safety First" is widely preached and the nation is slowly being educated to develop a safety habit of mind, though it would be obviously bad if all of us in consequence became over-cautious and were unprepared to take justifiable risks.

Enough is known about the generalities of the subject to make it possible to write about them in text-book form, and we know of no one more capable (both from his past experience and sympathetic attitude) to do this than Dr. H. M. Vernon. His book should be widely read, and will prove of particular value to safety officers and those others who are concerned in protecting their operatives. It deals, however, with much more than factory accidents, which are, as we know, only a small proportion of the total—there are accidents in the home, on the railways and most of all on the roads. Whereas the factories can be reached by legislation, the prevention of accidents elsewhere depends on a number of factors.

The question of the causes of the terrible loss of life and limb on the roads is far too thorny a one to be discussed in a review. It is a world problem and so serious as to constitute a major problem: it is known that it is receiving careful study on the lines discussed by Dr. Vernon in three of his chapters. The public at large is so obsessed with the desire for speed as to be unmoved by a casualty list which would spread horror in war time.

As against the danger of the roads, the railways have been rendered entirely safe by attention to the elimination of the risks. The air is relatively safe as the result of stringent regulations based on scientific study. The loss of life on an ill-found ship is followed by a searching inquiry and the fixing of responsibility.

There is very definitely a science of accident prevention, and it is to be hoped that this informative and valuable book will come into the hands of the largest possible number of readers.

E. F. A.

Cinematographic Anthropology

We, the Tikopia:
a Sociological Study of Kinship in Primitive Polynesia. By Dr. Raymond Firth. Pp. xxv + 605 + 25 plates. (London: George Allen and Unwin, Ltd., 1936.) 30*s*. net

THE cinema is characteristic of the age. It responds to a craze to see from an arm-chair an exact likeness of the reality in which we daily move. This spirit has invaded the social sciences. Archæology is giving up the attempt to *explain* civilization; its highest ambition is to photograph it at any given period. Anthropology has caught the infection in the most virulent form, because it is fatally easy to visit some obscure tribe, bring back continuous verbal pictures, and reel them off in volume after volume.

While we sit in our arm-chair, there pass before the mind's eye "sullen grey days with lowering clouds", the "sun-bleached thatch of sago palms", "down-drooping velvet-surfaced leaves of the taro". We can hear a servant's quavering laugh of fright, chubby little things welcoming father home, and (twice, p. 174 and p. 239) mother being notified of baby's lapse from propriety. As Dr. Firth sagely remarks, "banality about a tropic dawn is difficult to avoid when the scientist tries to range himself with the writers of fiction and belles lettres" (p. 51); but the temptation to indulge in belles lettres about the South Seas is too strong, and we have to resign ourselves to sit through an interminable "series of vignettes" (p. 110) for the sake of an occasional one which may be valuable because it serves for generalizations.

We have to sit through much that we might see at home. Read Cornwall, Manitoba, Peru for Tikopia in par. 1, p. 89, par. 3, p. 128, par. 3, p. 160, etc., and it will apply. Do we really send expeditions to the Antipodeans to come back and tell us that they are men who eat, work by day, and sleep by night, whose children cuddle up to them, and who may be good or bad parents?

So many of these "slices of life" (p. 89) are trivial. By that we do not mean small. An accent is a small thing, but it is not trivial because it has laws, alters sounds and affects etymology. Dr. Firth's excursion into "that unprofitable study, the etymology of Polynesian words", might have been more profitable if he had noticed the laws of Polynesian accent (p. 70). But to know that Sukimataranga is a bit of an acrobat (p. 14) is no good to anyone, and therefore trivial.

These vignettes are indeed accompanied by a commentary designed to bring out their scientific value. Unfortunately, the commentary often takes the place of the facts. The oft-repeated excuse is that space is lacking for complete "documentation". Surely room could be made by jettisoning lists of points there is no space to discuss (for example, pp. 429, 432), fine writing, trivialities, jettisoning even some of the texts. Text *S*.11, p. 244 might figure in a grammar, but the fact that it was heard used by a mother to her son does not make it a kinship phrase. Thus ample room could have been made for more of those illuminating statements by natives which Dr. Firth distributes all too sparingly (pp. 113, 191, 305, 332). His very valuable documents on conception (pp. 480 ff.) reward us for much long-suffering. Chapter xiii is one of the most useful because there Dr. Firth comes nearest to following his own advice that "the observer's theoretical explanations should be separated from the account of the actual happening" (p. 423).

Interpretations are no substitute for the "documents". Dr. Firth's interpretation is that for Tikopians English phrases have a talismanic value, but what Pa Tekaumata said was that they are a useful monopoly (p. 39). We should have liked to hear a Tikopian comment on the lines "your sky stands in the ocean" (p. 289), but the voice is Dr. Firth's in a 'belletristic mood'. A more prosaic interpretation is possible: "sky" in parts of Polynesia means "tomb". Compare these commentaries with Miss Alice Fletcher's "Hako" and it will be seen how much anthropological workmanship has fallen off in the last thirty-two years. As there is no vocabulary, we cannot check the translations.

Considered as contributions to theory, some of Dr. Firth's reflections are worth pondering, for example, on avoidance of kin (p. 322), and of the mother-in-law in particular (p. 314), on kinship and procreation (p. 247). Too many, however, are platitudes inflated with an uncouth phraseology. We knew that different societies have different marriage rites; the only thing we did not know was that it could be expressed as having "each their own mechanisms for dealing with the problem of transferring the major allegiance of a woman from her parents to her husband" (p. 574). It sounds more profound than it is to say that "a system of ownership of land is a mechanism of social stability" (p. 407), while to say that Tikopia "is not a community where the differential possession of wealth is an overt feature in the social structure" is longer but conveys no more than "there is no pronounced inequality of wealth" (p. 372). The functional school has fallen under the spell of the social science jargon of America, where it conceals the poverty of ideas.

Ideas are not the strong point of this book, facts might have been if the Tikopians had been allowed to speak for themselves throughout.

A. M. HOCART.

Fifty Years of Plant Physiology

An Introduction to the Principles of Plant Physiology
By Prof. Walter Stiles. Pp. xviii + 615 + 5 plates. (London: Methuen and Co. Ltd., 1936.) 27*s*. 6*d*. net.

THE publication of this book is, in some respects, a noteworthy event, as it is the first reasonably complete treatise on plant physiology published by a British author since the work of Vines in 1886. The enormous development of the literature of the subject during that period is illustrated by the long list of references included in this volume. This consists almost entirely of the more important papers published since that date. The present volume, therefore, deals almost exclusively with the plant physiology of the last fifty years.

It is of interest to compare the more noteworthy advances which are evident. The concepts underlying all branches of the subject have, of course, gained greatly in precision and, usually, they can now be illustrated by quantitative data. Especially noteworthy are the great advances in our knowledge of the properties of the leaf pigments and to balance this, a comparable clarification of the dynamics of photosynthesis. We can now distinguish mentally the role of diffusion, of photochemical change and of 'dark' reaction, even though the details of these stages in plants may still lack precision. Equally well advanced, in the relative sense, is knowledge of the absorption and conduction of water and of solutes by plants. The principle of osmosis had indeed already been established fifty years ago. But though we may now at least conceive (if with some misgivings) how water may be transported up a tree, we have been presented with still another problem in the physiology of conduction, that of accounting for movement of solutes through the phloem at rates of the order of tens of thousands of times greater than those observed in diffusion.

Again, although enormous strides have been made in understanding the mechanism of respiration, particularly in yeast and other fungi, the possible connexion in plants between fermentation and ærobic respiration, already suggested fifty years ago, is still not conclusively proved or disproved. In spite of much research, the problems involved in nitrogen and fat metabolism in plants still largely defy simple or comprehensive treatment; and considering the advances made in genetical knowledge, we are still curiously ignorant of the cell nucleus as a biochemical or physiological unit. Similarly, though very considerable advances have been made in the description and dynamical analysis of growth and of tropistic movements, it is only quite recently that much success has attended inquiry into the mechanisms underlying these phenomena.

In order to discuss such a variety of subjects adequately, Prof. Stiles, of necessity, has had to limit his treatment. He has done it by assuming a general knowledge of chemistry and by dealing mainly with the cardinal principles involved. These are considered under four main headings; (1) the general physiology of the plant cell (including respiration); (2) metabolism; (3) the physiology of growth and development; and (4) that of irritability and movement. In the introduction, the author expresses the hope that the book will be useful to undergraduates reading for pass and honours degrees. There is no doubt that this will be the case, and the treatment is, moreover, sufficiently comprehensive to make it also a valuable source of information to botanists in general. The author's name is a sufficient guarantee that it is well written, that its material is reliable and its conclusions well founded. In fact, only one slip, that in the formula for γ-fructose on p. 151, has been detected.

To some extent, the limitations imposed in choosing and compressing the available material must rightly tend to stifle criticism. Such a work as this must be viewed as a whole and not as a series of isolated chapters, and there are few who could or who would care to deal adequately with so many and such varied topics One reader might prefer to see more space devoted in the chapter on salt absorption to recent work on the energy relations of this process. The fundamental property of plant cells of accumulating ions against the concentration gradient seems to demand this treatment. Again, there are certainly some workers who would prefer to use the terms protease and peptidase rather than to employ pepsin and erepsin, on the grounds that the latter terms are not necessarily applicable to the majority of proteolytic enzymes in plants. The reference to cytochrome may possibly be regarded as somewhat brief, and the paragraphs dealing with sexual reproduction suggest that reference to recent work on sex differences might also be included. These features, however, detract from neither the broad scope nor the general utility of the book, and might well be allowed to be matters of individual preference. W. H. P.

Biological Control of Insects

The Biological Control of Insects: with a Chapter on Weed Control. By Prof. H. L. Sweetman. Pp. xii +461. (Ithaca, N.Y.: Comstock Publishing Co., Inc., 1936.) 3.75 dollars.

MUCH that has been written on the subject of biological control is of a scattered and rather fragmentary character. Some of these writings record successful application of the method; others are biological studies more or less incidental to practical issues; while a few are attempts to formulate the general biological principles involved The factors governing success or failure, where biological control is put into practice, are generally manifold and complex. We do not understand the operation of these factors sufficiently to be able to forecast an end-result with any certainty. Each project is of the nature of an experiment in itself which may, or may not, give the desired practical outcome.

The amount of information and data now available fully justifies judicious sifting and embodiment in book form. Prof. H. L. Sweetman is, consequently, to be congratulated on being the writer of the first text-book solely devoted to biological control. It had its inception, he tells us, in some teaching courses on the subject which he gave at the Massachusetts State College. The book is essentially scientific in outlook and acquaints the reader with the life-cycles, habits, methods of manipulation and of utilization of various organisms employed, or likely to be utilized, in schemes of biological control. It is, therefore, not wholly devoted to parasitic and predaceous insects. The general principles of parasitism and other phenomena come in for discussion, while the biological control of noxious plants forms the subject of a separate chapter.

Without going further into detail, the book is to be recommended as a sound introduction to the subject, which is treated from a broad point of view. It is both well arranged and well illustrated, while the literature is adequately covered in the 30 pp. of bibliography. Admirable as the book is, one cannot overlook the fact that it has been compiled to some degree by lifting whole paragraphs bodily from the writings of others. These excerpts bear neither parentheses nor reference numbers to the literature concerned. They are either copied verbatim or with some trivial alterations only. Such practices do not militate seriously against the undoubted value of the book, but they are disconcerting, and so is one of the portraits, which is not that of the person it is stated to represent.

A. D. IMMS.

Principles and Practice of Fruit-Growing

Hardy Fruit Growing
By Sir Frederick Keeble and A. N. Rawes. Pp. xi +334 +21 plates. (London: Macmillan and Co., Ltd., 1936.) 16*s*. net.

THIS is not a text-book, and it is certainly not a scientific treatise, but it is nevertheless one of the most valuable additions to horticultural literature we have had for some time. It is merely an unusually lucid, explanatory account of the practice of fruit-growing and an exposition of the scientific principles underlying the art. Chapter and verse for the statements made are not given, indeed only one reference to an original paper is quoted in the whole book, but so thorough and complete is the knowledge and so authoritative its presentation that one is left with the feeling that, even in subjects where controversy does exist, the methods advocated by the authors will at least give excellent results. The Worshipful

Company of Fruiterers, to whom the book is dedicated, is owed a debt of gratitude for conceiving the idea of so happy a collaboration. It is safe to predict that this volume will be the standard guide and reference book for many years to all who grow outdoor fruit.

The book is divided into three sections; Section 1 deals with the making and maintenance of the orchard and fruit garden, and comprises the main reading matter of the volume, in contrast with Section 2 which is intended for reference only. In this first section, the treatment of the subject of pruning requires special mention. All too often in works on practical horticulture this subject is treated in one or other of two ways. Either an attempt is made to describe in detail, often with complicated figures, the precise point at which any particular type of shoot should be cut, without more than a half-hearted effort to explain the why and wherefore, or else an involved account is given of the objects of pruning and the novice is left to infer for himself what to do in particular cases. In the book under review, the subject is treated in logical order, beginning with what pruning does and then explaining very clearly how to do it.

The chapter on where and where not to plant is also very well done, for advice on where not to plant is of as much importance as its more positive opposite, but is rarely to be found.

Section 2, however, will be to the experienced grower as well as the novice the most permanently valuable part of the book. It gives in condensed form details of culture, propagation, choice of varieties, and the more important pests and diseases and their control, for each kind of fruit separately. The amount of condensed information is astonishing. As would be expected from one who knows varieties so intimately as Mr. Rawes, the selection of varieties for different purposes is admirable and displays far more critical appreciation than in any previously published lists.

Section 3 is intended to serve as an introduction only to commercial fruit-growing. It is very short, and admittedly far from complete. Perhaps the best piece of advice in it is the indispensability to the commercial grower of Seabrook's "Modern Fruit Growing". The separate chapter on strawberries under glass is presumably added as information on this specialized line is difficult to get.

The format of the book is attractive and the print and paper of the usual high standard to be expected of the publishers. If a criticism may be made it is that more illustrations might usefully have been included. Those given are very good and mostly helpful, but refer mainly to apples. There seems no obvious reason why pear scab should have been picked out as the only fungal disease to be illustrated. However, it is refreshing to find that the usual valueless illustrations of one or two of the best-known apple varieties to be found in every other book of the kind have been omitted.

R. H. S.

Gem-Stones

A Key to Precious Stones

By Dr. L. J. Spencer. Pp. vii+237+8 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1936.) 5*s*. net.

DURING the past thirty years or so, much more interest has been taken, both by those in the jewellery business and by those who purchase their wares, in that part of mineralogy which is concerned with the stones used in jewellery. The former have found it imperative to be better informed about the stones that come into their hands, because of the increasing number of minerals which are being drawn upon for ornamental purposes. This moderately priced book is the latest on the subject, and comes from one whose career has well equipped him to write it. Dr. Spencer spent his official lifetime in the service of the Trustees of the British Museum, retiring as keeper of minerals, and in 1904 he gained an extensive grounding in the subject by translating Max Bauer's great treatise on precious stones.

The book is arranged on the usual plan. The first part, which is slightly the shorter of the two, deals with such portions of physics, chemistry and geology as are required for the proper appreciation of the properties of gem-stones, and the second part is concerned with the description of the several species. In his preface, Dr. Spencer points out that the determination and naming of the stones can be correctly done only with some knowledge of the principles of mineralogy.

Considering the long experience enjoyed by the author, it is strange that this book, which purports to be the key to the subject, should lack the lucidity and accuracy in the information wanted in practice. The characters generally used for the discrimination of cut stones are the specific gravity and the refractivity, especially the latter. In describing the use of heavy liquids in the determination of specific gravity, Dr. Spencer gives details of the elaborate set of tubes which he says that he has used for thirty years; but omits any reference to the diffusion column which is so convenient for a rapid test. A much more serious matter is the incomplete and inaccurate description of the refractometer and its use. He appears to have had little personal experience with this instrument; otherwise he would not state that in doubly refractive stones the greatest and least of the refractive indices may be found only if the facet under test is cut in a certain direction, whereas, as is well known to students of the subject, any facet will serve. Two interesting chapters on the geological occurrence and origin of precious stones and on their mining are included in this part of the book.

In the second part the properties and occurrence of the mineral species that have been used as gem-stones are discussed in twelve chapters. In order to keep the number of chapters so small, the second rank of species are grouped in pairs—spinel and chrysoberyl, beryl and topaz, garnet and tourmaline, zircon and olivine—and a host of minor minerals appear in the penultimate chapter, the final one as usual being devoted to the organic gems. In view of their importance, diamond and corundum with its well-known varieties, ruby and sapphire, are discussed in separate chapters, and both quartz and jade have been segregated. Opal has been linked with silica-glass; the author joined an expedition to the Libyan Desert to study the origin of the latter substance, a fact which perhaps explains the space devoted to its description, as it is unlikely to fill more than a humble place in jewellery. At the end of each chapter is appended a useful summary of the characters of the several species.

The book is illustrated by many drawings which appear in the text as well as by plates. There is also a plate in colour showing the principal gem-stones, but by a curious whim of the publishers it is printed on the dust-jacket. Considerable difficulty is still experienced in achieving a faithful reproduction of gem-stones in colour, and that in the present instance the result is far from true is not surprising. The key to the plate appears on the end-papers front and back. A good index adds to the value of the book.

Radio Communication for the Student

Wireless Engineering
By Prof. L. S. Palmer. Pp. xii+544. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1936.) 21*s*. net.

PROF. PALMER'S book on wireless was published in 1927 under the title "Wireless Principles and Practice"; the present edition bears the title "Wireless Engineering". This change of title is a consequence, we are told in the preface, of a rearrangement of the book and of the introduction of new matter. Comparison of the two editions, however, shows that as regards arrangement the new edition is very like the old, the heads of chapters and sections being almost identical.

As the arrangement of matter seems open to serious criticism, we summarize here the contents of the chapters to show their order: wave motion, theory of oscillatory circuits, description of miscellaneous apparatus and of aerials, theory of some special circuits, theory of thermionic tubes, description of spark and arc plant, theory of triode oscillators and descriptions of plant, wave propagation, detection of oscillatory currents, amplification, telephony and directional wireless. This order of presentation inevitably leads to difficulties in exposition and to the multiplication of forward and cross references. Also, clearly, the interpolation of a chapter dealing with a miscellany of apparatus between two chapters on the theory of oscillatory circuits cannot facilitate the task of learners. Similarly, the intrusion of a chapter on ancient spark and arc plant into the midst of the theory of triodes and triode oscillators produces another awkward break. Again, the chapter on directive aerials at the end of the book suffers by its distance from the section dealing with aerials in general. We had hoped that the opportunity of rearrangement opened by the call for a new edition would have been taken more wholeheartedly.

This lack of logical order in the chapters is often echoed inside them. For example, in the chapter on wireless circuits and aerials we find brief statements about dielectric losses, square law condensers, measuring instruments such as thermocouples, the self-capacity of coils, selectivity, together with photographs of great masts. It is to be regretted that these various items were not transported to happier positions during the preparation of this second edition. Similar comment may be made on the chapter on the detection of high-frequency currents, for this winds its tortuous way from coherers and crystal detectors to mercury arc plant for power stations, from the heterodyne method and the forgotten ticker to loud-speakers and the acoustic design of their horns.

These defects of arrangement do not, however, prevent a wireless expert from appreciating the general accuracy and wide variety of the information afforded, and the lucidity of the descriptions and explanations. But the wealth of small detail is sometimes fatiguing, and the procession of facts is sometimes packed so tight as to give an air of breathless haste. This, though useful as a memory refresher for the experts, may offer difficulties to the students for whom the book is intended, especially as the living and growing tissue is not distinguished from the dead wood.

In bringing a book on wireless engineering up to date, some authors would be influenced by the fact that in these days the number of wireless engineers concerned with apparatus for receiving signals is vastly greater than the number of engineers working on transmitting gear. But Prof. Palmer has not bothered about this; and therefore, we think, he has given far too little attention to, say, filter circuits, the matching of circuits, the use of padding condensers for yielding a constant-frequency difference between two varying circuits, decoupling connexions, and variable selectivity devices, all of which are necessities to the practising engineer, and, moreover, form instructive exercises for students. Further, in the chapter on thermionic tubes, the screen grid tetrode, perhaps the most important of all modern inventions in this field, gets short shrift, and the variable mu valve passes without any blessing. As for the great series of modern forms of tube, ranging from the pentode to the octode, and including such combinations as the duo-diode triode, these all remain unhonoured. Even such an important modern receiver as the superhet, of which hundreds of thousands are in use, gets less attention than the long-discarded arc transmitter, of which only odd examples survive.

Many wireless engineers and many students will no doubt feel that it would have been more helpful to them if these matters had been given some of the space allotted either to obsolescent things or to the analysis of the ionosphere, even though this last is admirably done and has intrinsic interest for physicists.

Infancy of Chemistry

Prelude to Chemistry:
an Outline of Alchemy, its Literature and Relationships. By Prof. John Read. Pp. xxiv + 328 + 64 plates (London: G. Bell and Sons, Ltd., 1936.) 12*s*. 6*d*. net.

THE early ages of chemistry possess a romantic glamour unshared by those of any other major science, which perhaps explains why chemists are so generally interested in the history of their subject. Prof. Read's interest reaches the level of enthusiasm, and though he expressly disclaims to have attempted to add to the formal literature of chemical history, his book—which may be appropriately classed among the *belles lettres* of chemistry—could have been written only by a scholar deeply and widely read in both primary and secondary authorities. His guiding principle has been to show the cultural relationships of alchemy, examining the numerous points of contact it made with religion, philosophy, mysticism, magic, mythology, literature and even music, and exhibiting it in proper perspective against its general social and intellectual background.

This treatment of the early history of chemistry is something quite new, and in Prof. Read's hands has resulted in a book of peculiar charm. An easy style, a nice sense of words, and a whimsical humour that never descends to facetiousness, add attractiveness to a story that has often been told, but rarely, if ever, in so delightful a manner. The professional historian of chemistry will, it is true, find few facts here that he did not know before, and may perhaps regret, according to his personal preferences, that certain periods and persons have received disproportionately small attention; but he will nevertheless enjoy the colourful tapestry of medieval alchemy which Prof. Read has woven with characteristically delicate skill. The general reader may be happy in the assurance that nothing of significance in recent work on the history of chemistry has escaped Prof. Read's notice. He mentions, for example, Prof. A. J. Hopkins's ingenious colour theory of alchemy, Prof. Tenney L. Davis's notable researches on Chinese alchemy, and Prof. J. R. Partington's investigations of chemical origins, as well as the work of Prof. Julius Ruska and others on Arabic chemistry; and in every case—as throughout the book—he is eminently successful in selecting the points of real interest and importance.

A further source of pleasure is provided by the admirable collection of illustrations, including a coloured frontispiece of the exquisite "Peacock in the Vase of Hermes" from a British Museum MS. of the "Splendor Solis". Alchemy relied very largely upon pictorial representation, so that its tenets cannot be properly appreciated without continued reference to such graphic aids ; the "Mutus Liber" (included in Manget's "Bibliotheca Chemica Curiosa") claims indeed to set forth the whole of Hermetic philosophy in a series of unannotated pictures.

Count Michael Maier (1568–1622) pressed another of the arts into the service of alchemy, setting to music—presumably of his own composition—Latin epigrams on secrets of "Chymical Nature". Prof. Read had the excellent idea of persuading a St. Andrews choir to learn and to sing some of these alchemical fugues, and since their rendering has been perpetuated in a gramophone record, anyone who wishes may hear it. In this part of his work he has had the assistance of Mr. F. H. Sawyer and Prof. H. J. Rose, whose modern chemical canon, "Hydrogenesis", written and composed in imitation of Maier's, shows 'a pretty wit' : "*Aëre cum crasso tenuis componitur aër ; adde Iouis fulmen, fit sonus, unda manet.* With a dense gas a thin gas is mixed ; pass the electric spark, and pop ! you have water." But it must have been Prof. Read who so thoughtfully added : "$2H_2+O_2=2H_2O$" !

E. J. HOLMYARD.

Quantitative Organic Microanalysis

Quantitative Organic Microanalysis of Fritz Pregl

By Dr. Hubert Roth. Third English edition translated from the fourth revised and enlarged German edition by E. Beryl Daw. Pp. xvi+271. (London : J and A. Churchill, Ltd., 1937.) 18*s*.

THE brilliant yet painstaking investigations of the late Prof. Pregl have placed quantitative organic microanalysis on such a sure footing that not only have such methods been widely adopted but also improvements and additions are constantly being introduced. Indeed, to-day, practically all the analytical procedures which the organic chemist is likely to require have been made available for him on the micro scale. This rapid development of the subject has made necessary a further edition of Pregl's well-known manual, which has now been brought up to date by Dr. Roth and translated into English by Miss Beryl Daw.

The book has been considerably enlarged and revised and, as hitherto, it opens with a section on the microchemical balance. To the matter in previous editions there have been added descriptions of a new Kuhlmann aperiodic balance, of two of the latest Bunge types, while a brief mention is made of ultra-microchemical balances.

The section dealing with elementary analysis has not been greatly modified A method of estimating carbon in the wet way is given, while the micro-Kjeldahl determination of nitrogen has been revised and a detailed description given of Friedrich's incineration with hydriodic acid. Other new procedures include a wet decomposition of halogen derivatives ; the determination of iodine as iodate ; the estimation of sulphur in the presence of nitrogen, chlorine and bromine

It is in the sections dealing respectively with the general groups and physical methods that the greatest alteration has been made, numerous new methods being included. These comprise the determination of active hydrogen by the Grignard reagent ; the titration of amino acids ; the volumetric determination of alkoxyl, alkylimino and S-alkyl groups ; the estimation of C-methyl and of isopropylidine groups ; catalytic microhydrogenation processes. New physical methods which are given include the microscopic determination of melting points ; the adaptation of Schleiermacher's principle to 'micro-boiling points' ; the determination of molecular weights by Barger's method of isothermal distillation ; the photoelectric measurement of absorption spectra ; the determinations of molecular refraction and specific rotation.

In the descriptions of the various procedures, there is given first a brief historical survey of the estimation, after which the apparatus and materials used are discussed. Then follows a very lucid and detailed summary of the course of the determination, while, finally, an actual sample analysis is given

The translator has performed her task quite creditably, although a number of small errors have been allowed to creep into the text. Fortunately, these are relatively unimportant, and do not detract from the great value of the book both to the organic chemist and to the analyst.

G. R. D

Short Notices

Archæology and Anthropology

The Dawn of the Human Mind:

a Study of Palæolithic Man. By R. R. Schmidt. Translated by Prof. R. A. S. Macalister. Pp. xxix+256+50 plates. (London: Sidgwick and Jackson, Ltd., 1936.) 12*s*. 6*d*. net.

DR. SCHMIDT in this elaborate and detailed study of the growth of mentality in primitive man, and more especially of *Homo sapiens* as he first appears as Cro-Magnon man, argues from both structure and the products of man's mind preserved in the archæological record. On one side, function is inferred from the development in organic evolution attained, more especially in growth and character of the brain, by the various early types of man from *Pithecanthropus* to *Homo sapiens*; and on the other, the basis of inference is the product, the artefact, interpreted as an indication of the mentality required to produce it, as well as of the cultural associations—social organizations, cults and the like—implied in its production. The analogy of peoples of backward culture of the present day support the argument with certain reservations.

Both lines of argument are familiar, though Dr. Schmidt is both bolder and more thoroughly logical than most in their application. The pioneer quality of his work, however, lies more particularly in the introduction of a third element into his analysis. This is interpretation through evidence afforded by a recapitulation in the child of the mental evolution of the race, analogous to the prenatal embryonic recapitulation of the phases of organic evolution. The argument is precarious, and in fact it is possible that no two observers would agree in drawing the line between this 'race-memory' and environmental influence. Nevertheless, by the aid of his theory Dr. Schmidt has produced an excellent and stimulating analysis of the culture of palæolithic man. Within its compass, his account of palæolithic art and his interpretation of it are as good as anything at present available. Prof. Macalister's translation of a difficult text is excellent.

Stone Age Africa:

An Outline of Prehistory in Africa. By L. S. B. Leakey. Pp. xii+218+14 plates. (London: Oxford University Press, 1936.) 7*s*. 6*d*. net.

DR. LEAKEY'S Munro Lectures for 1935–36, here expanded into book-form, present in summary a review of the evidence for the Stone Age in Africa. After a brief survey of the climatic and geographical conditions and the regional distribution of the distinctive fauna, recent and modern, the author gives an account of the cultural successions in East, South, North and West Africa, pointing out in dealing with the last-named that evidence at present is almost non-existent.

Recent progress in the study of African archæology has been rapid, and a correlation of this kind was badly needed. The task, however, is one for which an intimate knowledge of widely differing conditions is a necessity. In this respect there are few who are better qualified than Dr. Leakey. Nor is he afraid to assert an independent judgment, as will be noted in his critical attitude towards the work of his fellow archæologists in South Africa. In criticizing their system of nomenclature he raises a difficult question, on which for the moment it is perhaps best to reserve judgment. The extension of stone-age archæological studies to a world-wide field demands an open mind in approach to this question, until chronological and typological correlations have been more fully worked out.

Dr. Leakey does full justice to the valuable work of M. Vaufrey and other French archæologists in North Africa; but it is in East Africa, where he is on his own ground, that he is at his best. While accepting for the moment the criticisms which have been levelled at his chronological evidence, he argues inferentially for the early appearance of *Homo sapiens* in East Africa.

Misprints and slips in names and dates are regrettably frequent.

Naven:

a Survey of the Problems suggested by a Composite Picture of the Culture of a New Guinea Tribe drawn from Three Points of View. By Gregory Bateson. Pp. xviii+286+28 plates. (Cambridge: At the University Press, 1936.) 18*s*. net.

'NAVEN' is a ceremonial of the Iatmul, a head-hunting tribe of the Sepik River, New Guinea. Its preformance on occasions of importance in the life of an individual, more especially when something is done for the first time, as, for example, when a head is taken, has afforded Mr. Bateson the material for an elaborate study of the culture of the Iatmul people, in which different aspects of the one ceremony are made the basis of a detailed analysis of structure, emotional attitude and social relation.

Anthropologists who are interested in the origins of custom and religious ideas will find here much on which to exercise their theoretical faculty. This, however, is a branch of inquiry which Mr. Bateson deliberately eschews. His treatment is synchronous, and his theoretical interest is directed to the development of method in sociology and cultural anthropology on lines suggested by his investigation of 'naven'. The method here elaborated differs from the functional method of Prof. B. Malinowski, in so far as this is based upon the satisfaction of human needs. This the author consistently emphasizes, admitting, however, at the same time, that it is a development arising out of the practice of the functional school. So far, however, from discrete or classifiable needs affording the guiding principle, a single cultural element, such as the 'naven' ceremony, may be regarded from a number of aspects. Of these, three are considered here, the structural, the emotional and the sociological, and made, as it were, the matrix from which emanate lines of inquiry to embrace an analysis of the whole pattern of behaviour and the social complex. It deserves, and no doubt will receive, the careful consideration of all field anthropologists.

Biology

The Microscope

By Prof. S. H. Gage. Sixteenth edition, revised and enlarged by the addition of a Chapter on Micro-Incineration. Pp. viii + 617. (New York: Comstock Publishing Co., Inc., 1936.) 4 dollars.

This standard work passes to its sixteenth edition, which is thoroughly revised. Probably earlier editions are in the laboratories of every university and research institute, but there is not as much evidence in respect to their use as might be expected. Indeed, few laboratories can place at the disposal of their research workers the full equipment necessary for the microscopic examination of any animal or plant tissue. Teachers may explain the structure and use of a microscope, but cannot do more, since microscopy is a subject which can only be learnt by extended experience. The sole comparison of animal and plant tissues that have been killed, fixed and stained is out of date, and attention is concentrated first on the living tissues rather than on their artificial pictures; the final result has to be a composite, derived from all available means of observation.

As to the instruments, the bright-field microscope is generally mastered, but the dark-field, so invaluable for living organisms, is too little used largely because laboratories have no adequate illuminant for such. The polarizing and ultra-violet microscopes have limited use but must be available. The latter depends on the fluorescence of the substances, for example, chlorophyll giving red, and the living cells can be studied while the rays are affecting them; its use should be greatly facilitated by Dr. Gage's recent invention of an aluminium-vapour reflector, the film being deposited on polished quartz discs. No reference is needed to the chapters dealing with drawing, projection, mounting, section-cutting and other accessory technique as they show no great advances; for hæmatoxylin staining care should be taken that the Canada balsam used for mounting be alkaline.

Lastly, there is a useful chapter dealing with micro-incineration, as to which we first learnt as a practical process about four years ago, when a study was made of the distribution of the inorganic salts in the early development of the chick. The plan here is to eliminate the organic matter without unduly disturbing the mineral matter, which can be most conveniently studied on a dark-field; here spectrographic methods should also be useful.

Nature in Britain:

an Illustrated Survey. Introduced by Henry Williamson. With Contributions by R. St. Barbe Baker, E. G. Boulenger, L. C. Bushby, R. and E. Gathorne-Hardy, Seton Gordon and Frances Pitt. (The Pilgrims' Library, Vol. 3.) Pp. v + 250 + 97 plates. (London: B. T. Batsford, Ltd., 1936.) 5*s*. net.

This book, containing no less than 143 illustrations from photographs of animals and plants, written by experts in their several lines, is a remarkable production. Inevitably there must be compression, and the various chapters contain little more than brief descriptions and the more recognizable identification marks and habits of Britain's wild life. This, too, is necessarily unequal. While Miss Pitt tells us something about every one of our mammals, and Mr. Boulenger about our reptiles and amphibians, Mr. Seton Gordon cannot in thirty pages mention every British bird, or Mr. Bushby every one of several thousand insects.

As an introduction to the wild life of Britain which will compel even the blasé to take an interest, however, the book can be thoroughly recommended. It is simply written. The chapter on pond life is enough to send every boy off with a jam jar and net to the nearest pond. The illustrations are wonderfully clear, and give a good idea of the astonishing advances made in this department of photography. Where all is so good, it seems churlish to criticize, or to single out any particular chapter for praise. Nevertheless, the reviewer would have liked a little more information about certain quite common creatures; for example, there is no mention of the grass snake's offensive defensive, while "Do dragon-flies sting?" is a question only too frequently asked, and it is not answered here. Still, the amount of information given, and pleasantly given, is wonderful. If the youth of to-day is no longer interested in Nature, it is not for lack of inspiring and inspired naturalists

The Eggs of Mammals

By Prof. G. Pincus. (Experimental Biology Series.) Pp. ix + 160. (New York: The Macmillan Co., 1936.) 14*s*. net.

The subject of this book is the behaviour of mammalian eggs from the time of their genesis in the ovary to their implantation in the uterus. It opens with a discussion of the origin of the ovum, its growth and that of the follicle, and then passes on to its main theme, the physiology of fertilization, parthenogenesis and cleavage.

The mammalian ovum offers many special problems because of its close dependence on a particular environment, that of the maternal uterus, which is itself under the influence of various hormones elaborated in other parts of the body. These relationships are not yet by any means cleared up, but a promising beginning has been made in their investigation, largely by Dr. Pincus himself, many of whose results are here published for the first time. The author has also been responsible for important advances in the technique of handling and cultivating mammalian eggs outside the body, and has been able to initiate parthenogenetic development. It may be hoped that the remarkable phenomenon of ovarian atresia, the data on which are fully summarized, will throw some light on the conditions of activation of cleavage.

As is natural in a subject which has only recently been submitted to experimental analysis, the value of the book lies more in the questions which it raises than in any answers it may suggest; as the author states, "this is a book of interrogation, not explanation". It will be extremely valuable to those few who are already working in this field, and one may hope that it will lead to an increase in their number.

C. H. W.

The Principles of Bacteriology and Immunity

By Prof. W. W. C. Topley and Prof. G. S. Wilson. Second edition. Pp. xv+1645. (London: Edward Arnold and Co., 1936.) 50*s*. net.

It is not possible in a short review of this book to deal in any detail with the very extensive revision which has been carried out so successfully by the authors. Whole chapters have been rewritten and rearranged in order that the results of the very rapid advances which have taken place in bacteriology during the last few years could find their place. It is only necessary to read such chapters as those dealing with antigen-antibody reactions and virus immunity and to note the extensive additions which have been made in chapters on the Streptococci, *Brucella*, etc., to have some idea of the magnitude of the task undertaken and so thoroughly carried out.

The book has always been a really valuable work of reference, and we feel that the new edition will give it an even higher place in bacteriological literature. It will be more than a mere book of reference.

Part IV, which deals with applications of bacteriology to medicine and hygiene, will, we hope, be read by many who are not specialists in bacteriology. It might be considered as a thoroughly up-to-date textbook dealing with the practical problems of disease in man and the lower animals. To many of us this will be the most valuable, though perhaps not the most interesting, part of the book.

It is a book which every worker on the subject of bacteriology should possess and read and re-read. Our only criticism is that it is too bulky to read comfortably in an easy chair. We heartily congratulate the writers on the production of this excellent second edition.

J. M. Beattie.

The Animal's World

By Prof. Doris L. Mackinnon. Pp. xv+272. (London: G. Bell and Sons, Ltd., 1936.) 7*s*. 6*d*. net.

Too often the spoken word is lost. It was in response to many written requests by listeners to a series of broadcasts on simple biology in which Prof. Mackinnon took part that this entrancing book came to be written. As she explains in her modest preface, the author leans more to things zoological than botanical, and it is only when animals and plants become interdependent on one another that plant biology is introduced—hence the title.

Prof. Mackinnon has that rare combination—a wide and exact scientific knowledge with a facile and sympathetic pen. How animals move in air, in water, on land; how they breathe and why; how they talk to one another; what the world looks like through their eyes; why honeysuckle smells sweeter in the evening; why the heart beats; these and a hundred other questions she answers in the simplest and most direct language, such language that a child can understand and yet a grown-up can enjoy and learn from all the time.

Some of the most interesting chapters are on the senses of animals, especially those which deal with hearing and the ways in which animals communicate with one another. In connexion with the latter, an interesting example of the use of the microphone is given.

The book is profusely illustrated with many photographs of outstanding interest and beauty. In addition, there are drawings and diagrams which help to explain the text. There is also a comprehensive index.

G. M. V

British Grasshoppers and their Allies:

a Stimulus to their Study. By Dr. Malcolm Burr. Pp. xvi+162+6 plates. (London: Philip Allan and Co., Ltd., 1936.) 6*s*. net.

The sub-title of this little booklet expresses very neatly its purpose as a stimulus to the study of British Orthoptera, and there can be no question that it will serve the purpose in an admirable way. Although there are thirty-one species of Orthoptera and Dermaptera on the British list, they remain one of the most neglected groups of insects, and the distribution of the different species, to say nothing of their habits and ecology, are most imperfectly known. Determination of the recognized British species, and of such few as may be expected to occur in the British Isles, is very easy with the aid of short descriptions and figures of outstanding characters. Distributional maps are given for each species, but they serve mostly to show the lamentable paucity of records. General remarks at the beginning of the book, and scattered throughout its text, contain a host of suggestions for studies, both valuable scientifically and mostly easily carried out by any serious amateur naturalist.

The booklet, which is compact, well produced and cheap, should rapidly find its way into the pockets of field naturalists, with the desired stimulating effect on the accumulation of knowledge about this sadly neglected, but in many ways fascinating, group of insects.

B. P. Uvarov.

Aquariums and Fishponds

By A. Laurence Wells. (Warne's Information Series.) Pp. 64. (London and New York: Frederick Warne and Co., Ltd., 1936.) 1*s*. 6*d*. net.

Here are the main principles of fish-keeping and of the plants and animals suitable to an aquarium. Let it be square; cover the bottom with sand, then loam, and plant it with carefully sterilized vegetation.

Scatter the surface with pebbles, fill up and place it in the best light, taking care to cover with a glass plate to keep out dust—the organisms prefer vita-glass. When growth has commenced, introduce a few snails as scavengers, change ten per cent of the water weekly and remove debris. When all is well, introduce the fish, which must not be crowded. A pond may be constructed on the same principles and has the great advantage that the small crustaceans, insect larvæ, worms and other life will provide the necessary fish-food. For an indoor tank recourse must be had to dried foods, the best of which consist of the natural food dried, with small parts of meat, biscuit, egg and vegetable powder. We also catch live crustaceans —but any good food will do, provided that too much is not given. Chapters deal with the food and ailments of fish—we have found flavine most useful for fungus—and the plants are shown in thirty illustrations. This is a charming little book.

Cosmetic Dermatology:

with Dictionary of Ingredients; Discussion of Anatomic, Physiologic and Pharmacologic Bases of Cosmetic Application; "Shelf-tested" Formulary; and Appendices on Odor and Color in Cosmetics. By Dr. H. Goodman. Pp. xv+591. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 36*s*.

This encyclopædic work, which forms a valuable addition to dermatological literature, is divided into two unequal parts. The first, which is entitled "Dictionary of Ingredients", contains separate descriptions of the official drugs of the United States Pharmacopœia and of the unofficial drugs used in the treatment of skin diseases. The second part, which forms the bulk of the work and is devoted to practical cosmetic dermatology, consists of fifty-four chapters in alphabetical order (acne–vitamins) containing an account of various skin diseases and modes of treatment. There are three appendixes dealing respectively with cosmetic colours, perfumery and weights and measures

Color Changes of Animals in relation to Nervous Activity

By Prof. G. H. Parker (University of Pennsylvania: Leidy Memorial Lectures.) Pp. ix+74. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1936.) 7*s*. net.

This volume is a somewhat extended form of the Joseph Leidy Memorial Lecture in science delivered in March 1936. Prof. Parker's recent work has led him to the conclusion that the chromatophores in fishes are controlled by neurohumors which are liberated by nerves. They may be divided into two classes—the hydrohumors, such as the substance liberated by the pituitary gland, which are carried in the circulation, and the lipohumors, which are oil-soluble substances liberated by nerve endings in the skin and diffusing slowly from one area of skin to another. The book describes the experiments on which these conclusions are based. It is well illustrated and attractively produced.

Chemistry

Industrial Chemical Calculations:

the Application of Physico-Chemical Principles and Data to Problems of Industry. By Prof. O. A. Hougen and Dr. K. M. Watson. Second edition. Pp. ix+487. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 22*s*. 6*d*. net.

The title on the cover of this excellent book is a very modest one, and gives little indication of the wealth of information and instruction to be found within. The objective of the book is the development of concise and logical methods by which complex industrial chemical problems may be solved from fundamental scientific principles. Its study is intended not to replace but to supplement a course in physical chemistry, and to prepare the student for advanced courses in chemical engineering. The first nine chapters of Part 1 deal with the more ideal low-pressure system in which simple algebraic methods can be used, and the last five chapters treat non-ideal cases by more general and complicated methods, involving considerable use of the calculus. The first four chapters deal with weights and compositions, stoichiometry, ideal behaviour of gases, and vaporization and condensation respectively. Thermo-physics and thermo-chemistry are the subjects of the next two chapters, which are followed by chapters on industrial reactions, fuels, weight and heat balances of combustion, and chemical and metallurgical processes. A detailed analysis is made, for example, of the chamber acid process and of a blast furnace. Part 2 of the book deals with entropy, free energy, and the other thermodynamic potentials, and their application to the study of chemical equilibria. Here the method of treatment is most helpful to the industrial chemist who desires to make use of all the assistance thermodynamics can give but who lacks the technique.

Detailed solutions of typical problems illustrate the application and combination of the various principles which receive treatment, and emphasis is placed on the necessity of giving each individual step in the calculation, clearly labelled, in order that a correct result may be reached, capable of quick verification. At the end of each chapter, problems are presented for solution by the reader, since only through actual practice can skill in analysing and solving problems be attained. There are more than twenty tables which provide useful physical data for a whole range of chemicals, and there are nearly a hundred figures. The price should place this book within the reach of every industrial chemist who feels the need of a more exact and quantitative approach to his problems. R. T.

Elements of Chemical Engineering

By Prof. W. L. Badger and Prof. W. L. McCabe. (Chemical Engineering Series.) Second edition. Pp. xvii+660. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 30*s*.

The first edition of this book was noticed in Nature of October 10, 1931. Time has proved its utility in America to the increasingly large number of chemical engineers who have received a college training. Now that the Imperial College of Science is starting a full undergraduate course in the subject leading to a degree at the University of London, chemical engineering may be expected to attract more students in Great Britain.

The new edition follows the old closely, with the new work incorporated; the principal changes are to be found in the chapters on flow of heat, evaporation, drying, distillation, gas absorption, extraction and filtration. Such technical works are necessarily full of symbols, the precise meaning of which it is difficult for the reader to retain: it is therefore convenient to find at the end of each chapter a list of all the symbols used therein. It is stated that, so far as possible, these correspond to the recommendations of a Committee of the American Institute of Chemical Engineers.

The book contains an introduction by Arthur D. Little, who has passed away in the interim: he was the gifted and inspired leader of the movement to make chemical engineering a science of its own.

(1) Recent Advances in Physical Chemistry

By Dr. Samuel Glasstone. Third edition. Pp. viii+477. (London: J. and A. Churchill, Ltd., 1936.) 15*s*.

(2) Recent Advances in General Chemistry

By Dr. Samuel Glasstone. Pp. ix+430. (London: J. and A. Churchill, Ltd., 1936.) 15*s*.

(1) DR. S. GLASSTONE has earned the gratitude of many chemists by writing his "Recent Advances in Physical Chemistry"; the appearance of a third edition within five years is sufficient testimony to the widespread recognition of the value of his reviews of modern work. The new matter in this edition is largely concerned with the application of wave mechanics to problems of molecular structure, and gives an account of the valency bond and the orbital methods as applied to a number of structural problems as well as a discussion of resonance phenomena in organic molecules.

(2) The new companion volume on "General Chemistry" opens with an account of atomic disintegration, and includes articles on deuterium, on electron diffraction and on free radicals. It also includes the discussions on solubility and on acid-base catalysis which had been omitted from later editions of the "Physical Chemistry" owing to lack of space. It is, however, the chapters on statistical methods and on the mechanism of reactions in solution which the reviewer has most admired. For entirely different reasons both subjects are difficult to deal with in a limited space, but Dr. Glasstone has succeeded in giving a clear and readable account of the fundamental theory of the former, whilst the discussion of reaction mechanism is an excellent survey of theory and experiment.

Chemists will find the new volume as helpful and as interesting as the earlier "Physical Chemistry"; it would be difficult to give it higher praise than this. S. S.

Physical Chemistry

By Prof. F. H. MacDougall. Pp. ix+721. (New York: The Macmillan Co., 1936.) 17*s*. net.

THIS text-book follows more or less traditional lines in the order in which the subjects are presented, but it possesses some special features worthy of note. Thus the thermodynamical aspect of physical chemistry is given more emphasis than in most English text-books of a similar standard, and the exposition of the first and second laws and their application to chemical problems is admirably clear and concise. Electrode processes and the theory of the E.M.F. of cells are also dealt with thoroughly and without the ambiguities which often mar the treatment of these subjects. Much modern work is included and the sections on extranuclear atomic structure and on theories of strong electrolytes may be mentioned as clear and useful introductions to these topics. S. S.

Disperse Systems in Gases:

Dust, Smoke and Fog: a General Discussion held by the Faraday Society, April 1936. Pp. 1041–1300. (London and Edinburgh: Gurney and Jackson, 1936). 12*s*. 6*d*. net.

AN article on some points raised in the general discussion organized by the Faraday Society on "Disperse Systems in Gases" appeared in NATURE of May 2, 1936. The papers, which are now available, are considered under the general properties of such systems and their industrial aspects, the latter being quite a short section though of great importance in relation to the amenities of life. We are all plagued by dust, by fog and by the deposition of dirt from smoke; many of the ills of the flesh are a consequence of their preventable existence. Dust produced in industry is the subject of legislation where it causes occupational diseases, but dust produced in the streets or in our homes, which we breathe laden with bacteria, is no one's concern. Nor is there any serious effort to restrict the production of smoke except by factory chimneys, in spite of the fact that so many alternative smokeless fuels to raw coal are available.

The Faraday Society was more concerned with the theoretical aspects of the question, the size of particles, their movement and the cohesion between particles. Many very useful papers are collected under the sub-heading of mist, cloud, hygroscopic nuclei, town and country fogs.

The discussions were most valuable and it will prove useful to have them in book form for reference.

A Text-Book of Inorganic Chemistry

Edited by Dr. J. Newton Friend. (Griffin's Scientific Text-Books.) Vol. 6, Part 5: Antimony and Bismuth. By W. E. Thorneycroft. Pp. xxviii+249. (London: Charles Griffin and Co., Ltd., 1936.) 18*s*. net.

THE volume of Dr. Friend's well-known text-book dealing with antimony and bismuth maintains the high standard of the series. The chemistry of these two elements is particularly difficult, and the author has wisely adopted a rather conservative attitude, in which the compounds are regarded as containing the element existing in one of two valency states, 3 and 5. The information includes the mineralogy and technology of the elements as well as the pure chemistry, and the physical constants of the elements and compounds are given in detail.

It is regrettable that a higher standard of accuracy in historical information is not generally required in text-books; in the present volume, two names are incorrectly given in one line on p. 14, for example. References to analytical methods are adequate. The literature appears to have been very well covered until about 1933, but there do not seem to be many references after this date. It should be noted that neither Thenard nor Regnault should be written with an accent.

Geography

The Preservation of our Scenery:

Essays and Addresses. By Dr. Vaughan Cornish. Pp. xiii+92+12 plates. (Cambridge: At the University Press, 1937.) 7*s.* 6*d.* net.

To Dr. Vaughan Cornish beauty of scenery is no mere luxury but a factor in the formation of national character, and he regards its preservation as essential to national well-being. Fortunately, there is a growing, but not yet sufficiently influential, body of opinion that subscribes to this view. The study of the mechanism of Nature is less important than its philosophical contemplation, and wild Nature must be protected from both the devastation of the builders and road makers and the frenzy of the collectors who may be termed the criminal classes among Nature lovers.

In the volume before us, Dr. Cornish has collected six papers and addresses which he has given to various societies on the subject of the preservation of the scenic amenities of Great Britain, and he has illustrated the volume with several of his charming sketches. One of the papers discusses the types of scenery suitable for national parks in England and Wales and the relative value of certain areas from this point of view. Another contains a strong plea for the preservation of English cliff scenery, and this is an even more urgent matter since the destructive hand of the bungalow builder is making serious inroads on some of our cliffs, notably in Cornwall.

All who value the beauty of our countryside will welcome this volume. It may be too much to hope that the vandals of our natural heritage will realize their iniquity from its pages, but the indifferent may be persuaded to abandon that attitude.

Markets and Men:

a Study of Artificial Control Schemes in some Primary Industries. By J. W. F. Rowe. Pp. ix+259. (Cambridge: At the University Press, 1936.) 7*s.* 6*d.* net.

One of the solutions for the economic troubles, which have recently 'depressed' production throughout the world, has been some form of control. The schemes have varied greatly. They have involved a world limitation of output to a percentage of the normal—tin, copper, rubber; paying the farmer not to produce certain products—cotton, wheat, hogs; actual destruction of the crop—coffee.

After a preliminary chapter on the origin and growth of artificial control schemes, the author describes those for coffee, wheat, sugar, American cotton, rubber and tin, and discusses the troubles which give rise to restriction schemes.

The language is simple, and the book is a useful record of experiments, the success or propriety of which is to-day a matter of keen controversy in political and economic circles.

Geology and Mineralogy

Rutley's Elements of Mineralogy

23rd edition, by Prof. H. H. Read. Pp. viii+490. (London: Thomas Murby and Co.; New York: D. Van Nostrand Co., 1936.) 8*s.* net.

The homely saying that the proof of the pudding is in the eating is well exemplified by this well-known text-book, now in its twenty-third edition, which has guided the footsteps of so many generations of students of mineralogy.

In Part 1, which deals with the properties of minerals, the chapters on crystallography and optics have been rewritten and a new chapter on the occurrence of minerals has been added. In the discussion of the elements of crystallography the treatment has been kept as simple as possible. Nothing, for example, is said about the reflecting goniometer, and only the eleven more prominent of the thirty-two classes of crystal symmetry are considered; possibly the number might have been expanded slightly so as to include the cuprite class in the cubic system, the chalcopyrite class in the tetragonal system, and the sulphur class in the orthorhombic system. Prof. Read follows all writers, except some in Great Britain, in the use of the Bravais symbols in the hexagonal system in place of the original Millerian indices. From the excellent account which is given of the optical properties of minerals the student can acquire the fundamental knowledge necessary in the determination of minerals by means of their optical characters, particularly in thin sections of rocks. The chapter on the occurrence of minerals is really an introduction to petrology and the subject of ore deposits.

In the second part, which comprises the description of minerals, the usual chemico-crystallographical classification originated by Dana has been given up in favour of one based upon economic and chemical considerations, the minerals being grouped according to the useful element contained in them and the order following the periodic classification of the elements. Care has been taken to retain the important rock-forming silicates in their natural families. Under each mineral the properties are clearly stated and attention is directed to the discriminative characters which serve to distinguish it from others with which it might be confused.

The usefulness of the book is greatly increased by the large number of excellent illustrations which are interspersed in the text and by the copious index. It is, indeed, a book which may be commended to every student of mineralogy, from whatever angle the subject be approached.

Getting Acquainted with Minerals

By G. L. English. Pp. xi+324. (New York and London: McGraw-Hill Book Co., Inc., 1934.) 15*s*.

The veteran author of this book has long been known to those interested in the acquisition of minerals. In 1886–1904, he was actively engaged in mineral dealing under the trade name of George L. English and Co.; for the following nine years, until 1913, he was monazite expert to the National Light and Thorium Company; and finally he returned to his old life, first until 1921 as manager of the mineralogy and petrography department and then until 1934 as consulting mineralogist of Ward's Natural Science Establishment. Thus for forty-eight years he has dealt with minerals, and many of the American specimens obtained by collectors during those years have come to them through his agency.

In this book the author gives the amateur collector the benefit of his long experience. It is not and is not intended to be deeply scientific. In the first part a general but superficial account is given of the physical and chemical properties of minerals, which will serve to induce the reader to take still greater interest in the specimens already in his collection and those he hopes to acquire. Part 2 is devoted to the descriptions of minerals. As the Dana system of classification which is normally used in mineralogical text-books demands considerably more scientific knowledge than the author expects of the ordinary reader, he has adopted a classification in which the species are arranged according to the most important elements in their composition, a cross-reference being given where necessary, while the important group of rock-forming minerals are brought together in the second section. In Part 3 the rocks are briefly considered in three sections: igneous, sedimentary, and metamorphic. Part 4 is an important and original feature of the book. In it an attempt is made to identify any mineral specimen by means of three simple and obvious characters: lustre, hardness, and colour. It is a method which may be expected in skilled hands to yield good results. A novel feature of the book is the pronouncing vocabulary at the end.

The author has added to the usefulness of the book by introducing in the text a large number of drawings and illustrations from photographs, and the ample index is a great advantage.

Interpretative Petrology of the Igneous Rocks

By Prof. H. L. Alling. Pp. xv+353. (New York and London: McGraw-Hill Book Co, Inc., 1936.) 24*s*.

The igneous rocks arise by processes taking place in the physical chemical system of the magma, and the study of the genesis of these rocks is largely concerned with the application of physical chemistry to these systems. Few geologists, however, have this fundamental knowledge—their training has been too broad. It is the aim of this book to present to the geologist those principles of physical chemistry that will enable him to interpret the life-history of these rocks. The phase rule and its application to igneous systems are the basis of the treatment.

The principles of equilibria, solid solution, isomorphism and polymorphism are first examined, and then the various groups of the igneous rock-forming minerals are considered as solid solutions of end-members, or *minals*, and their thermal diagrams and optical properties dealt with. Then follows a series of what may be called essays on numerous topics of petrogenesis, such as the crystallization of magmas, diversification of igneous rocks, magmatic assimilation, end-stage processes, and many more.

Whether or not the author has succeeded in his intention of making physical chemistry plain and easy for the geologist—and opinion will certainly be divided on this point—he has at least written a book of great interest to petrologists already learned in this subject. He has, too, provided refreshing and stimulating essays on all those theories that make modern petrology so entertaining. The small scale of some of the illustrations, and a few rather awkward misprints mar an otherwise well-printed book.

Mathematics

An Illustrated Historical Time Chart of Elementary Mathematics:

for Senior and Secondary Schools, Training Colleges and Universities. By E. J. Edwards. In 5 sections, each 31in. × 22in. (London: University of London Press, Ltd., 1936.) Thick cardboard, varnished, 21*s*. net.

Many teachers of mathematics recognize the advantage of associating the subject with its history, but find difficulty in doing so in the time available. If they decorate the walls of their classrooms with Mr. Edwards's attractive charts, they will have available a stock of interesting information, illustrated with diagrams, maps and portraits, to which incidental reference can be made when appropriate.

The first chart (Beginnings of Mathematics) deals with primitives, Babylon, Egypt and China up to 2000 B.C. The second (Early Mathematics of Egypt, Babylon and China, 2000–1000 B.C.) sketches the development of integers and fractions, and of intuitive and practical geometry. The third (Ancient Greece, 1000–30 B.C.), perhaps the best of the five, deals with the work of seventeen famous mathematicians. The fourth (Dark Ages, Arab School) brings the account up to 1000 A.D. The fifth (Decline of Arabian and Beginning of European Mathematics. Modern Mathematics, 1000–2000 A.D.) attempts too much. Up to the time of the invention of the calculus the chart is good, if overcrowded (a fault emphasized by the lettering, which is more artistic than legible), but it would have been better to have omitted all reference to the eighteenth and nineteenth centuries rather than give such a meagre account, ignoring even Euler and Lagrange. The publishers might fill up the blank space (nearly a column) with matter selected from H. W. Turnbull's "The Great Mathematicians" (especially p. vii), or the works of F. Cajori and G. Prasad. H. T. H. P.

(1) Logarithmetica Britannica:

being a Standard Table of Logarithms to Twenty Decimal Places. By Dr. Alexander John Thompson. Part 7: Numbers 70,000 to 80,000. (Issued by the Biometric Laboratory, University of London, to commemorate the Tercentenary of Henry Briggs' publication of the "Arithmetica Logarithmica", 1624.) (Tracts for Computers, No. 20.) Pp. vi+102. (London: Cambridge University Press, 1935.) 15*s*. net.

(2) Tables of the Higher Mathematical Functions

Computed and compiled under the direction of Harold T. Davis. Vol. 2. (Published as a Contribution of the Waterman Institute for Scientific Research, Indiana University.) Pp. xiii+391. (Bloomington, Ind.: The Principia Press, Inc., 1935.) n.p.

(1) This part, the seventh to be issued, contains the logarithms of numbers from 70,000 to 80,000, leaving two parts still to appear. There are some interesting reproductions to illustrate the relation of Henry Briggs to Napier's "Constructio Canonis".

(2) The first volume of these tables appeared in 1933 and was reviewed in Nature. The present second volume maintains the high standard attained by the first. Tables 13–28 give the first four derivatives of the psi functions at varying intervals and from 10 to 19 decimal places. There is here some overlapping with Vol. I of the British Association Tables which appeared, as the director observes, when his work was far advanced. Tables 29–39 are concerned with Bernoulli's and Euler's numbers. Tables 40–49 give data for polynomial approximation up to the 7th degree. The volume gives errata to Vol. 1, and if the list is reasonably complete, the authors are to be congratulated on the small number of errors in so large an undertaking.

L. M. M-T.

Mathematical Snack Bar:

a Collection of Notes and Results. By Norman Alliston. Pp. vii+155. (Cambridge: W. Heffer and Sons, Ltd., 1936.) 7*s*. 6*d*. net.

This is a very unusual book and therefore somewhat difficult to review in a short notice. It comprises a collection of miscellaneous notes and conclusions in both geometry and arithmetic. As the author points out, a roving investigator accumulates a considerable amount of original material; but gleanings here and there do not necessarily provide the ingredients for a connected thesis. The apt title of the volume gives some clue to its contents, in so far that no single theme is systematically developed.

The text touches upon Diophantine analysis, Heronian triangles, theory of numbers, residues and many geometrical problems off the beaten track. Although the mathematical treatment is quite elementary, some very interesting facts are presented, notably in the determination of rational parts of a triangle, the expression of a biquadratic as a square, problems on tangencies and Fermat problems. There are indeed so many really valuable mathematical 'snacks' in the book that it is a great pity there is no reference index. A few minor inaccuracies in the print are noticeable; for example, index omitted on p. 2; sign in line 25, p. 25 and n for x on p. 87, line 3.

Elementary Analytical Conics

By Dr. J. H. Shackleton Bailey. Pp. v+378. (London: Oxford University Press, 1936.) 7*s*. 6*d*.

This interesting volume, by the headmaster of the Royal Grammar School, Lancaster, provides an elementary course in analytical conics for the use of pupils preparing for the various Higher Certificate Examinations and for scholarships. It opens with a lucid introduction showing that the conics are really plane sections of a cone—a vital point so often overlooked. Then follow seven chapters on the point, straight lines, equations and the transference of axes, the circle, parabola, ellipse and hyperbola. Chapter viii is devoted to a discussion of oblique axes, whilst the final section contains one hundred examples from recent Higher Certificate papers.

The course is thoroughly sound, and develops an admittedly difficult subject for beginners in a very stimulating way. The various parts, so often dealt with piecemeal, are here woven into a coherent whole, and special emphasis has been rightly laid upon parametric representation. The text is excellently printed and arranged, the principal formulæ being summarized at the end of each chapter.

The book may be confidently recommended, for the author has well fulfilled his aim by providing a sound foundation of the elements of co-ordinate geometry in a very attractive way which is admirably suited to the needs and age of sixth form pupils.

Interpolation and Allied Tables

Reprinted from the Nautical Almanac for 1937. Pp. ii+44. (London: H.M. Stationery Office, 1936.) 1*s*. net.

There is no wholly satisfactory text-book on interpolation, especially on the practical side. The Nautical Almanac staff have a wide experience of interpolation and sub-tabulation, and they have developed methods which appear to be superior to those generally known. This pamphlet will serve a useful purpose in making such methods more widely known, and the explanations are full enough to make it a working manual of interpolation for those who have an elementary theoretical knowledge of the subject. The method for inverse interpolation is new, and possibly more convenient than any of those already published. Special attention is directed towards 'critical tables', which are used without interpolation and have a maximum error of only half the usual amount. H. T. H. P.

Metallurgy

(1) The Journal of the Institute of Metals
Vol. 58. Edited by G. Shaw Scott. Pp. 325 + 30 plates.

(2) Metallurgical Abstracts (General and Non-Ferrous)
Vol. 2 (New Series). Edited by G. Shaw Scott. Pp. vii + 889.

(London: Institute of Metals, 1936.)

(1) "Metallic Wear" formed the subject of a general discussion at the last annual meeting of the Institute of Metals. The opening paper by Dr. H. W. Brownsdon is given in this volume, together with a record of the discussion, in which no fewer than twenty-one experts expressed their views on this important subject. Following the presidential address of Mr. W. R. Barclay, in which he dealt with organized development in the non-ferrous metal industries, are fourteen papers and related discussions, including "Effect of Molten Solder on Some Stressed Materials", "Test for Zinc Coating on Wire", "A Deep Drawing Test for Aluminium", "Magnesium Copper Alloys", "The Physical Properties of Nickel Silver Alloys" and "Experiments on the Electrical Resistance of Copper Wires". The volume concludes with an account of Mr. C. C. Paterson's May Lecture on "The Escape of Electricity from Metals: Its Practical Consequences". The author traces the effect which the liberation of the electron from metals has had on the trend of electrical engineering during the past twenty years.

(2) The second volume of "Metallurgical Abstracts" is larger than its bulky predecessor by ninety pages—a fact indicative of the ever-increasing volume of metallurgical work that is being published all over the world. The field covered includes properties of metals and alloys, corrosion and protection, electrodeposition, refining, analysis, apparatus and instruments, testing, temperature measurement and control, foundry practice, scrap metals, furnaces and fuels, refractories, heat-treatment, working, joining and the cleaning and finishing of metals. The present volume contains upwards of 10,000 abstracts, the index to which alone occupies 146 pages. It is indispensable to everyone concerned in any way with the use or application of metals and alloys. One omission which is still noticeable is a list of publications from which abstracts are regularly prepared.

Corrosion Resistance of Metals and Alloys
By Robert J. McKay and Robert Worthington. (American Chemical Society Monograph Series, No. 71.) Pp. 492. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1936.) 35*s*. net.

The remedy for corrosion in many cases is the use of the right alloy in the right place. The authors have taken this as a text in writing their book, which summarizes up-to-date information on the corrosion resistance of all the ferrous and non-ferrous alloys of any importance at all.

The first part of the book sets out to classify and explain the important points of the theory or mechanism of corrosion. The second and longer portion consists of detailed data on the corrosion of individual materials in given conditions. Chapters are devoted to: magnesium and its alloys, aluminium and its alloys, zinc and zinc coatings, cadmium plate, tin and tinplate, lead, iron and steel, molybdenum alloys, chromium alloys, chromium plate, nickel-iron alloys, nickel, nickel-copper alloys, copper, and high copper alloys. Each chapter gives a general discussion of the behaviour of the material, followed by a documented survey of knowledge of its resistance to a wide range of corrosive conditions, and an extensive bibliography.

In employing this method of presentation, metal by metal, the authors realize that it has the shortcoming that the answer to the question "What metal is best to use?" or "Is copper better than lead for sulphuric acid?" may not readily be apparent. But a uniform system of presentation enables a rapid comparison to be made once a preliminary selection of likely materials has been effected. The latter process is facilitated by a form of master-chart giving a cross-section of corrosion rates for each metal group in each of seven typical corrosive conditions. If the data given are then interpreted on the basis of the fundamental considerations set out earlier the reader will be able to obtain a clear idea of the material best suited to his purpose. It will thus prove invaluable to all metallurgists, chemical engineers and others who are faced with the problem of selecting materials to withstand particular conditions.

Miscellany

Changing Man:
the Education System of the U.S.S.R. By Beatrice King. Pp. 319. (London: Victor Gollancz, Ltd., 1936.) 10*s*. 6*d*. net.

Not even political prejudice can conceal the fact that the communist Russia to-day represents an immense social experiment of far greater interest and significance in political and social thought than the reversion to autocracies represented by modern Fascism. The success or failure of Communism under the conditions of to-day, whether in the execution of its successive five-year plans, or in the vastly enhanced extent to which the scientific worker has been placed in control, or again in the attempt to make the service motive a driving force comparable with that of the profit motive elsewhere, depends as much on education as on any one factor. In this book we are given a survey of the education system of the U.S.S.R., which should at least assist in judging as to the chances of success.

The survey is admirably done and apart from the larger question, the scientific worker will find much to interest him in the account of technical and professional education, of educational research, of higher education, discipline and examinations, etc. On many points of detail it is clear that the practice of Soviet Russia might well be adopted to some extent in our own educational system, as for example, in the efforts made to regulate the number of students entering different types of technical schools in accordance with industrial requirements, so as to prevent dislocation of industry or of social life. Similarly, the course of social science which is compulsory in university education might perhaps be adopted with advantage in our own system.

The author has given us a book which cannot well be passed over by anyone who, whatever his political creed, is interested in the impact of science on society and the capacity of man to adapt himself to new conditions.

The Philosophy of Religion *versus* The Philosophy of Science:

an Exposure of the Worthlessness and Absurdity of some Conventional Conclusions of Modern Science. By Albert Eagle. Pp. 352. (Manchester: The Author, University; London: Simpkin Marshall, Ltd., 1935.) *5s.*

THIS book is a somewhat emotional outburst written in an extremely unconventional style and evidently intended for the non-scientific reader. The author is a mathematical lecturer but he is violently opposed to 'relativity' ideas in physics and astronomy. He raises an interesting question too often overlooked by mathematicians—Is not mathematics merely a shorthand of symbols? Are not the fundamental realities of space and time based on the structure of our own minds and not on facts independent of us but observed by us? Is there a fundamental distinction between what Bergson calls 'duration', which is real time, and mathematical time, which is a convenient fiction? Was T. H. Huxley right when he said that mathematics is not a science but a machine?

Another object of the author's attack is the materialistic philosophy as preached by some biologists. It is well known that quite a number of biologists do hold the view that all the peculiar features of life are to be accounted for by the chemical composition of protoplasm, but this is not true of all; and as the author says, the most distinguished physiologists repudiate this conclusion. Dr. Eagle especially objects to a recent book on popular biology by some of the younger biologists—all of them specialists in narrow fields—in which occur dogmatic statements about materialism being the ascertained conclusion of science, and also on the nature of heredity and the method of evolution. Such a book is calculated to injure the cause of science by associating it in the popular mind with 'mechanistic' philosophy and morals.

E. W. M.

The Digestive Tract:

a Radiological Study of its Anatomy, Physiology and Pathology. By Dr. Alfred E. Barclay. Second edition. Pp. xxxvi+427. (Cambridge: At the University Press, 1936.) 36*s.* net.

IT is not surprising that within a very short time a second edition of a book of such outstanding merit as Barclay's "The Digestive Tract" should be called for. The foundation laid by the first edition is, however, so solid that, little being required in the way of alteration, the author can be content with merely bringing the book up to date. He introduces notes on the latest developments in technique, such as X-ray cinematography, a branch of the science of radiography, at present in its infancy, which should prove of great utility in investigations of the movements of the digestive organs in health and disease.

The author has for many years been concerned about the safety of workers in X-ray departments; it is reassuring to find that he now allows a higher safety limit of exposure than that laid down in his first edition.

The book not only has an appeal to the systematic reader who wishes to study the subject in its entirety, but also it will undoubtedly give many hours of pleasure to the more casual reader who merely wishes to 'browse'. It is written by one who is not content with blindly accepting the 'dicta' of his predecessors, who not only looks at his subject from widely different angles, but who also consistently probes beneath the surface. The illustrations throughout the book are of the highest quality and much may be learnt from a perusal of these alone.

Whilst appreciating that the book represents a radiological study of the anatomy, physiology and pathology of the digestive tract, one cannot help feeling that its value would be enhanced by a fuller account of the clinical aspects of the lesions described. This is not by way of a criticism, but is put forward as a tentative suggestion worthy of consideration in future editions.

R. E. ROBERTS.

Scientific Progress

(Sir Halley Stewart Lectures, 1935.) By Sir James Jeans, Sir William Bragg, Prof. E. V. Appleton, Prof. E. Mellanby, Prof. J. B. S. Haldane, Prof. Julian Huxley. Pp. 210. (London: George Allen and Unwin, Ltd., 1936.) 7*s.* 6*d.* net.

THE Sir Halley Stewart Lectures, 1935, reproduced in this volume were dealt with in NATURE at the time of their delivery. The collected volume offers the opportunity of intercomparison in relation to the aims of the Sir Halley Stewart Trust, with their concern for the prevention and removal of human misery, the social relationships of man, the development of body, mind and spirit in the individual, of just environment in the community, and of "peace on earth" through international goodwill. The placing of the six lecturers in this series on "Scientific Progress" is an excellent, if highly individual and invidious, exercise. One reader would unhesitatingly put J. B. S. Haldane first, would hesitate between Mellanby and Huxley for second place, and with renewed firmness put Sir James Jeans last. So much for a physicist's view. What would the biologist say?

Social Hygiene To-day

By H. E. Garle. Pp. 387. (London: George Allen and Unwin, Ltd., 1936.) 12*s*. 6*d*.net.

WITH some remarkable exceptions, such as Abraham Flexner, the authors of works on prostitution and venereal disease have been medical men. The present work is remarkable as emanating from a barrister-at-law, who possesses no medical qualification.

The book is divided into two parts. The first consists of ten chapters dealing with various aspects of prostitution and venereal disease, while the second part contains a digest of laws relating to prostitution and venereal disease in different countries. There are numerous appendixes dealing with international agreements made at Paris and Geneva for the suppression of the traffic in women and children and the facilities given to merchant seamen for the treatment of venereal disease, followed by a bibliography classified according to anthropology, biology and physiology, psychology, social applications and venereal diseases.

Albrecht van Borgunnien's Treatise on Medicine

(Sloane MS. 3002, British Museum). By W. L. Wardale. (St. Andrews University Publication, No. 38.) Pp. xlvii+80. (London: Oxford University Press, 1936.) 10*s*. 6*d*. net.

THIS work is a fifteenth century medico-astrological treatise written in Eastern North Low Saxon by a certain Albrecht van Borgunnien, about whom nothing further is known. Almost the whole text, which consists of a prologue and remedies for various diseases, appears to be founded on a methodical leech book which contained charms of a popular character and various medico-astrological treatises.

In addition to numerous external and internal remedies, the subjects dealt with in the work include urinoscopy, phlebotomy and the signs of the Zodiac, the four elements, the four complexions and the signs of life and death. A glossary and short bibliography are appended.

Estimation of Vitamin A

SOON after the Second International Conference on Vitamin Standardisation (1934), it became apparent that the value of 1,600, which the Conference had provisionally allotted to the factor for converting results of spectroscopic tests for vitamin A into international units, might need reconsideration[1].

The Vitamin A Sub-Committee was reluctant to undertake experimental work on this problem which, it was hoped, would be settled before long by published work. When, by the autumn of 1935, this hope had not been realized, the Sub-Committee proceeded to collect unpublished data of biological and spectroscopic tests for vitamin A in various materials. These showed certain anomalies, which in the state of knowledge existing at the time, could not be harmonized. For example, a consistent series of biological tests, particularly of concentrates, showed a conversion factor of about 1,000–1,200, while equally consistent tests with some cod and halibut liver oils seemed to require a value nearer 2,000.

Further experimental work on this subject was therefore initiated by the Vitamin A Sub-Committee. The co-operation of as many laboratories as possible was enlisted, so that the results should command the maximum of confidence, and show whether any part of the discrepancy was due to variations in technique. It was obvious that with biological tests the most trustworthy results would be obtained by confining attention to a small number of materials and using as many experimental animals as possible. It was decided to investigate first whether the act of saponification, presumably effecting hydrolysis of the esterified vitamin, resulted in any change which might influence the conversion factor. Halibut liver oil, as the richest common source of vitamin A, was the material chosen. The Sub-Committee is indebted to Messrs. Parke, Davis and Co. for a quantity of a rich oil which was mixed with an equal quantity of an oil manufactured in Aberdeen.

The preparation of the concentrate and the dilution of the feeding-solutions of oil and concentrate, as well as the spectroscopic examination of all the materials including the carotene standard at the beginning of the experiment, and of the residues of the feeding-solutions from each laboratory at the end, were in the hands of Dr. R. A. Morton and Dr. J. R. Edisbury of the University of Liverpool. A special dilution of the β-carotene standard for use in the biological tests was prepared in the Department of Biological Standards of the National Institute for Medical Research. Special precautions were taken to minimize deterioration of all these materials, and great emphasis was laid on the importance of the tests for stability made on the residues of the actual solutions used for feeding. Sources of variation in technique, apart from the choice of basal diets and general treatment of the animals, were eliminated as far as foresight would permit. All the diluted feeding solutions were derived from one batch and distributed to the participants, ready for use. The relative, though not the absolute, dosage to be used was fixed and each worker used one dropping pipette for all the materials. The bottles of test material were stored continuously in a refrigerator from the time of arrival, only the approximate amount needed for dosage on any day being withdrawn at one time.

The materials were prepared in April 1936, and the last of the tests was completed in the following October.

The participants in the biological tests were:

A. L. Bacharach and E. L. Smith, Glaxo Laboratories, Ltd., Greenford.
W. A. Broom, Messrs. Boots Pure Drug Co., Ltd., Nottingham.
H. M. Bruce and K. H. Coward, Pharmaceutical Society, London.
A. D. Emmett and O. D. Bird, Messrs. Parke, Davis and Co.'s Detroit Laboratories (communicated by J. A. Freeman).
E. M. Hume, Lister Institute, London.
S. K. Kon, National Institute for Research in Dairying, Shinfield.
T. Moore, Dunn Nutritional Laboratory, Cambridge.
S. W. F. Underhill, Messrs. The British Drug Houses, Ltd., London.
H. Wilkinson, Messrs. Lever Bros., Ltd., Port Sunlight.

The results showed a surprising degree of harmony. They are now being subjected to a statistical examination. There will necessarily be some delay before this is completed, but it seems unlikely that the general conclusion will be modified. A preliminary announcement of the results is thought to be in the general interest.

After a suitable correction, to weight the means obtained according to the number of rats used by the different participants, the conversion factor for the halibut liver oil was found to be 1,470, the range of the individual values being 1,400 to 1,700. For the concentrate the values were lower, most of them lying between 1,000 and 1,200.

The spectroscopic tests for stability of the solutions administered, however, made it clear that while the halibut liver oil solution had remained relatively stable throughout the period of the tests, deterioration had occurred in the solution of the concentrate. When the individual tests were corrected for the degree of deterioration, the low value for the conversion factor disappeared, and little doubt was entertained that, in the case of this concentrate, its instability was sufficient to account for the lower values obtained. Since this deterioration took place in spite of special precautions, it seems possible that other vitamin A concentrates might behave in the same way.

It is concluded therefore that:

(1) In view of the margin of error inherent in the biological tests, the above results, giving a conversion factor of 1,470 for a halibut liver oil, provide no support for changing the value of 1,600 recommended by the International Conference (1934) for the conversion factor.

(2) Many apparent discrepancies with concentrates are likely to have been due to unsuspected deterioration in the course of biological tests, so that independent control of this source of error is essential.

(3) The ground has now been cleared for further experiments designed to test supposed variability of the conversion factor in materials derived from different species of animals.

Further co-operative experimental work is contemplated on other alleged discrepant materials from different sources, and, for this purpose, information regarding other materials showing well substantiated discrepancies would be welcomed.

Chromosome Behaviour and Phylogeny in the Neuroptera

THERE has been disagreement on morphological and palæontological grounds as to the relationship of the groups of true Neuroptera and Megaloptera. In the first place, take the family Sisyridæ of the true Neuroptera (or Planipennia). Its members possess aquatic larvæ, and as they have some morphological features in common with Osmylidæ, the larvæ of which are semi-aquatic, Tillyard[1] in 1916 put forward the suggestion that it had to be regarded as a comparatively late offshoot of the latter. This view was then adopted by Withycombe[2], and recently Killington[3] in his admirable monograph of the British Neuroptera maintains the idea that "these two families are no doubt closely allied, and, indeed, it appears very probable that the Sisyridæ have been derived from an Osmyloid ancestor". On the other hand, Handlirsch[4] was not of the opinion that the families were very nearly related, and pointed out that Sisyridæ show a remarkable similarity with the then oldest known fossil remnants of true Neuroptera, that is, the Triassic Prohemerobidæ, the larvæ of which are supposed to have been aquatic also. Recently, Handlirsch[5] (and Beier), after having considered the discoveries of true Neuroptera in the Permian by Tillyard[6] and Martynov[7], also directs attention to the striking resemblance of some of these very old remnants with the living Sisyridæ, which group he still regards as a primitive and primarily aquatic one. Tillyard[8] seems later to have given up his original view and regarded Sisyridæ as "a specialized side branch" not very close to Osmylidæ. After much dispute, therefore, morphologists have come to no agreement on the relationships of the two groups.

The evidence of chromosome behaviour, on the other hand, proves to be unequivocal. From the work of Naville and Beaumont[9] we know that in Planipennia, including the Osmylidæ, the males possess an X and a Y chromosome, which show what Lorbeer has called "distance conjugation", that is, in the first meiotic metaphase the sex chromosomes always lie near the opposite poles of the spindle, apparently not having been in touch earlier. This property is not found in any other group of Insecta, and is extremely rare elsewhere. Now the Sisyridæ, which so far have been cytologically unknown, differ from all Planipennia, in having a normal behaviour of the sex chromosomes (Fig. 1 *a*, *b*). This is shown by their behaviour in *Sisyra fuscata*, which has $2n = 12 + X + Y$ in the male. X and Y pair like the autosomes in the first metaphase. (The stainless space between X and Y in the figure is a connexion, the existence of which is proved by a case where the XY-complex is bent at this point without any dislocation of their near ends.) This, I think, supports the view of Handlirsch.

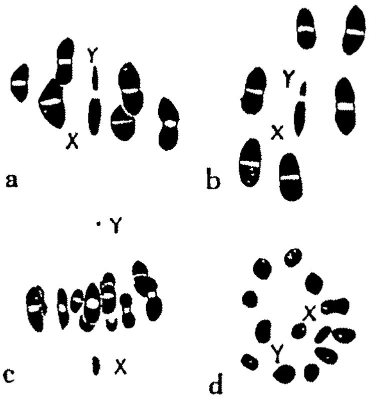

Fig. 1.

FIRST MEIOTIC METAPHASE OF *Sisyra fuscata* (*a*, *b*) AND *Raphidia xanthostigma* (*c*, *d*). PERMANENT ACETO CARMINE SMEARS, SLIGHTLY PRESSED.

Consider now the Megaloptera (Sialoidea and Raphidioidea). They have long been regarded as a single group remotely related to Planipennia. Thus Killington[3] does not include it in his comprehensive work. Tillyard[6], however, after having found fossils of Raphidioidea from so early a time as the lower Permian, and considering also the discoveries of Sialoidea by Martynov and himself from the same period, now considers these two groups to be as different *inter se* as they are from Planipennia. He refuses to give them ordinal rank as Handlirsch did (cf. also Withycombe[2], p. 401).

The chromosomes of a species of Raphidioidea, the whole group previously having been unknown cytologically, are shown in Fig. 1, *c*, *d*. The males have an XY-pair of sex chromosomes, the Y being very small, dotlike. These chromosomes show the "distance conjugation", known otherwise only among insects in Planipennia, and suggest a relationship with this group. The number of chromosomes in the male of the species investigated, *Raphidia xanthostigma*, is $2n = 24 + X + Y$.

The chromosomes of Sialoidea are described only in Japanese by Ito[10]. From his figures, however, I do not find any evidence of the occurrence of "distance conjugation" of the sex chromosomes. The number of chromosomes is $2n = 18 + X + Y$ in *Chauliodes* *japonicus* and $2n = 20 + \alpha + \beta_1 + \beta_2$ in *Protohermes grandis*.

The opinion put forward by Tillyard in 1936 on palæontological grounds therefore seems to be supported by the cytological evidence. Raphidioidea may be even closer to Planipennia than to Sialoidea, and the distinction between Megaloptera and true Neuroptera therefore unsound.

Note added in proof. Since writing the present note, I have received an article by Naville and Beaumont *Arch. d'Anat. micr.*, 32, 1936), which shows the same behaviour as I have found in another species of Raphidia.

Duality of the Reversibly Oxidized Forms of Vitamin C and the Polarization of its Dienol Group

OUR recent work[1] on oxygen absorption of acid vitamin C solutions suggested the existence of the oxidized form: vitamin + ½ O, or vitamin − H. This form corresponds to the first step of the reversible oxidation of the vitamin, deshydroascorbic acid being the second. New evidence corroborates the duality of the reversibly oxidized forms of vitamin C. Phosphomolybdic acid ($P_2O_5(MoO_3)_{24} + 16\ H_2O$) mixed with an acid solution of vitamin C develops a blue or a green colour. The blue colour reaches its maximum intensity when the ratio $\frac{\text{ascorbic acid}}{\text{phosphomolybdic acid}}$ approaches $\frac{176}{3000}$. This colour fades when the quantity of the oxidizer, the phosphomolybdic acid, is diminished, and turns green when it increases.

The blue colour may be obtained not only by the consequent increase of the concentration of vitamin, but also by adding to the weak ascorbic acid solution a substance such as cysteine. This last substance is not capable by itself of giving any colour reaction with phosphomolybdic acid, but acts by lowering considerably the potential of the solution. The changes from the blue to the green reaction and vice versa evidently depend upon the potential. Therefore these reactions must be evidence of the existence of two reversibly oxidized forms of the vitamin. To make this clearer, we have produced the maximum blue and green reactions and treated the solutions with hydrogen sulphide. Testing the liquids (after removal of hydrogen sulphide) with the Bezssonoff reagent $[3(MoO_3 17(WO_3)P_2O_5 + 24H_2O)]$ and iodine, we find about 94 per cent of the vitamin which was present before the colour reactions.

We also ascertained that after precipitation of the green colour by means of neutral lead acetate, and lead with sulphuric acid, the liquid no longer gives the reactions of ascorbic acid. Later treatment with hydrogen sulphide restores the vitamin reactions.

Phosphomolybdic acid gives similar blue and green reactions with hydroquinol but not with pyrogallol, nor with various other polyphenols. Catechol gives a completely distinct yellow colour reaction; however, it possesses like vitamin C the common group COH : COH. The presence of such a group in the vitamin C molecule[2] is shown by the well-established formula of Hirst and confirmed by means of a titanium sulphate colour reaction (Ettori[3]).

Thus, phosphomolybdic acid gives identical colour reactions with hydroquinol and vitamin C, but not with catechol, in spite of the presence in these last two substances of the same dienol group (COH : COH). It is therefore evident that the dienol groups of vitamin C and hydroquinol are subject to a common influence which does not occur in the case of catechol.

The structure of hydroquinol, , and of vitamin C,

$$\mathrm{H_2COH\,.\,H\,COH\,.\,\overset{\ulcorner}{HC}\,.\,COH:COH\,.\,\overset{\urcorner}{CO}},\ \text{(O bridge between HC and CO)}$$

indicates that in both substances the dienol group is polarized. This peculiarity does not distinguish the enol groups of catechol and of pyrogalol.

Tyrosine in Diseased Pedipalps

THE value of X-ray methods in the identification of minute quantities of crystalline substances is well demonstrated in the following example. Dr. E. Warren has been studying part of the collection of Pedipalps (arachnids related to the scorpions) in the British Museum (Natural History), and in two series of *Hypoctonus formosus* Butler, from Further India, he has found evidence of a fungus disease (actinomycosis), which had affected at least 70 per cent of the specimens. Associated with the fungus centres, which are scattered throughout the tissues of the host, there are yellowish-white spherules measuring up to ½ mm. in diameter. These spherules are made up of radiating, birefringent needles which are probably pseudomorphous after the radiating fibres and hyphal tubes of an Actinomyces.

An X-ray photograph (using copper radiation) of one of the spherules yields a well-marked 'powder pattern' identical with a photograph of powdered artificial *l*-tyrosine, thus confirming Dr. Warren's preliminary determination based on solubility tests. Possible alternatives such as uric acid, the two hydrates of calcium oxalate, leucine, etc., are also excluded by their X-ray patterns. Moreover, two samples of *dl*-tyrosine, prepared by different methods, which were kindly sent to me by Prof. H. S. Raper, give patterns similar to, but not identical with, those of *l*-tyrosine. This distinction between *l*- and *dl*-tyrosine is enhanced in powder photographs of the hydrochloride derivatives. Hence tyrosine is present in diseased Pedipalps either as the *d*- or *l*-form, more probably the latter. It results from the decomposition of proteins in the host, and has been detected in vertebrates as a rare urinary sediment associated with acute yellow atropy of the liver, phosphorus poisoning and yellow fever.

The Lachish Letters and the Use of Iron Inks in Antiquity

THE documents found early in 1935 on the ancient biblical site of Lachish, and now known as the Lachish Letters, were brought to London on the return of the expedition. During the summer of 1935, at the request of Mr. L. J. Starkey, I submitted them to a chemical examination. At the same time I made a more general investigation of the subject of early inks.

A survey of the literature indicated a consensus of opinion that iron displaced carbon inks at some time during the Middle Ages. I found, however, that the ink used in these letters contained both carbon and iron.

The problem is complicated by the presence of ferric iron in the body and on the surface of the sherds, and it was necessary to develop a special technique for testing the microscopic particles detached from various positions within and outside the lettering. It was observed that the better preserved writing was richer in iron, and the more eroded characters were primarily carbon.

A further search of the literature gave evidence of the early knowledge of iron inks. An examination was therefore made of the material available in the British Museum, and it was found that most of the writing on vellum of the early Christian period was in iron free from carbon. The earliest of these was the second century leaf from a Codex, concerning which Kenyon[1] says: "The earliest extant examples (of vellum) are probably two leaves, one in the British Museum containing part of Demosthenes' De Falsa Legatione (B.M. Additional MS. 34,473 i) . . ." A minute fragment of this taken from a broken edge of a paragraphing line, after subdivision into portions of about 0·02 mm. in size, was tested under the microscope. This gave the reactions for iron, the ink being entirely soluble and leaving no residue of carbon. Of the third and fourth century vellum documents or fragments, three out of twelve were carbon. Among the nine of iron type is the Codex Sinaiticus, which is a good example of this carbon-free brown iron ink.

Iron inks are decomposed with time to brown ferric oxide and hydroxides, which in the case of these early vellum manuscripts, appear as an almost transparent gel, combined perhaps as a complex with the vellum.

It can scarcely be doubted that the writers of antiquity insisted upon an ink of good appearance, comparable when fresh with a carbon ink, and as in these examples carbon is absent, the iron must have been in combination with a gall or tannin extract.

The ancient world was well acquainted with iron inks and with the various combinations which could be made with carbon, copperas, oak galls and gum; and it was with such an iron and carbon mixture that the Lachish Letters were written.

A complete account of the work will be found in "The Lachish Letters. I. The Wellcome Archæological Research Expedition to the Near East", which is now in the Press.

Effect of Meteoric Shower on the Ionization of the Upper Atmosphere

OBSERVATIONS on the ionization of the upper atmosphere during a meteoric shower have as yet been very few in number and have all been confined to the Kennelly-Heaviside or *E* region. So far as we are aware, only two observations, one carried out in the United States[1] and the other in India[2], comprised direct measurements of the ion content of this region during the Leonid showers. Both gave strong evidence that ionization of this region increases enormously during such showers.

It seems natural to inquire if meteoric showers have any effect on other regions besides the *E* region of the ionosphere. Measurements with this object in view were carried out at Calcutta on five consecutive nights during the Leonid shower in November 1936. The dates of observations were centred around the night of maximum shower, November 14–15. The critical penetration frequency method was employed for the purpose; the range of frequencies used was 1–15 Mc./sec. Observations were made at intervals of one hour between 22.00 and 05.30 hours. The observed results are plotted in Figs. 1 and 2.

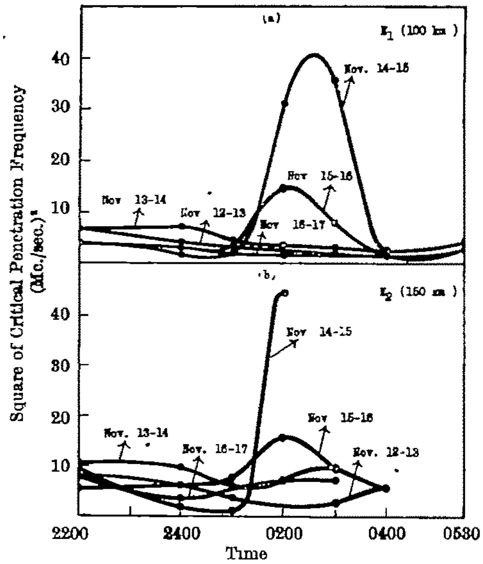

Fig. 1.

Fig. 1 (*a*), E_1 region. There is sharp increase of ionization between 01.00 and 04.00 hours, which is the period of maximum intensity of the shower in the nights of November 14–15 and 15–16.

Fig. 1 (*b*), E_2 region. Similar increase as in the case of E_1. The drop in the curve for November 14–15 could not be observed, presumably because the ionization fell below that of the E_1 region.

Fig. 2 (*a*), F_1 region. The ionization on an average diminishes for all the nights except for that of November 15–16.

Fig. 2 (*b*), F_2 region. The ionization on an average diminishes for all the nights.

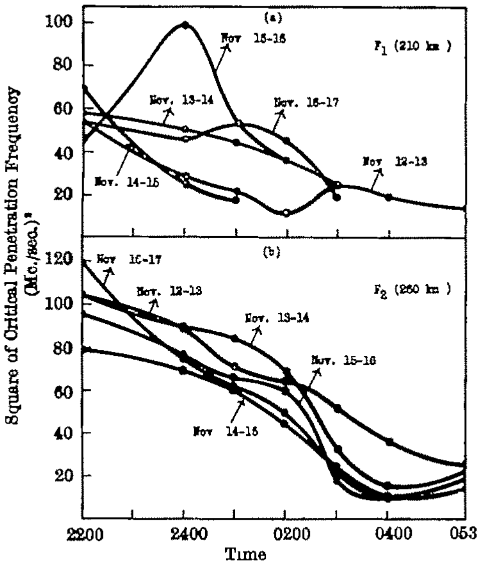

Fig. 2.

The increases in the ionization of the E_1 and E_2 regions (Fig. 1) on the night of November 14–15 are undoubtedly due to the impact of meteors. There was no other disturbing factor in this night. There might be some uncertainty with regard to the increases on the night of November 15–16 in E_1, E_2 and F_1 ionization, as there was a magnetic storm in progress during that night. Since, however, the time of increase in the ionization of E_1 and E_2 on this night corresponds, as on the previous night, to the hour of maximum intensity of the Leonid shower, and also since no significant correlation between a magnetic storm and abnormal increase of the ionization of these regions has, as yet, been found in our latitude, it may safely be inferred that these increases are also due to the meteoric shower. With regard to the increase in the F_1 ionization during the same night, it is very doubtful if meteors were responsible for this, since the time of increase does not correspond with the time of maximum shower. Further, as in the case of the two E regions, there was no increase of a similar nature on the previous night.

Since the heights of most frequent appearance and disappearance of meteors, visible to the naked eye, lie between 160 km. and 70 km., it is to be expected that any increase of ionization caused by the meteors should be confined within these limits. This is what has actually been observed. Though, in the course of our observations, we were able to detect each of the four distinct regions of maximum ionization, it was only the lower ones—E_1 and E_2—which were found to be affected by the meteoric shower. The fact that these regions showed increase separately and were not merged into one continuous region due to meteoric impact—as, at first thought, might have been expected—also receives an easy explanation if we remember that a region which is already ionized should undergo proportionately greater increase of ionization than a region which is not originally ionized.

An account of this work with fuller details will appear shortly in the *Indian Journal of Physics*. The author is indebted to Prof. S. K. Mitra and Dr. H. Rakshit for their kind interest in the work.

Figures of the Earth and Moon

A RECENT paper of mine, noticed in NATURE for February 27, p. 381, needs a correction, since the next issue of the *Monthly Notices of the Royal Astronomical Society* (p. 126) contains a correction by Prof. E. W. Brown to the calculated motions of the moon's perigee and node, which had stood for about twenty years. The change for the perigee is about three times what appeared to be the probable error of the previous value. Brown, in a letter to me, has queried the probable errors that I used; but provisionally retaining them until better estimates are available, I have made a new solution, which is: $J = 0{\cdot}0016361 \pm 0{\cdot}0000059$; $1/e = 297{\cdot}19 \pm 0{\cdot}52$; $J' = 0{\cdot}000316 \pm 0{\cdot}000024$; $K' = 0{\cdot}000115 \pm 0{\cdot}000048$; $f = 0{\cdot}69 \pm 0{\cdot}06$.

The ellipticity of the earth is only slightly affected; the chief change is in the ellipticity of the moon's equator, which is proportional to K' and is more than doubled. It is now almost midway between the two inconsistent values of Hayn and Stratton, and affords no ground for preferring either to the other. The coefficient of $g_e \sin^2\phi$ in gravity will be increased to $0{\cdot}0052917 \pm 0{\cdot}0000059$.

The need for a modern series of observations to determine the moon's librations in longitude is clear; in the above determination, K' rests entirely on the motion of the perigee. If it is correct, the period of the free libration in longitude should be close to 50 sidereal months and the amplitude of the annual forced libration 0·84′.

Planetary Positions at Sunset in 1937

THE hour after sunset is possibly the time most often chosen by many for noticing the bright planets, chiefly because Venus and Mercury scarcely let us notice them at any other time, except by insisting on inconvenient wakefulness before sunrise.

In the accompanying drawing (Fig. 1), and for the English sunset sky, the positions of the sun and the bright planets are indicated for the first day of every month of the year. Number 1 stands for the first day of January, 2 for the first of February, and so on, 13 standing for the first of January 1938. The positions of the setting sun on the first day of two months like January and December are not really the same, but they are sufficiently near to one point to be marked the same for the purposes of this diagram.

The positions of Mercury lie on a peculiarly tangled path, and the middle of April (the fourth month) seems the best time to look for that planet. It is then at a considerable altitude directly above the setting sun, but the small size of the spot marked 5—the spots are graded for relative brightness—indicates that the planet may not be very bright on those evenings. Venus will evidently be a magnificent object in March, over the south-west horizon and about half-way up to the zenith. The curve for Mars shows a singular loop in the autumn, and during August, September and October the planet is actually farther *east* each successive evening at the time of sunset. This loop, by the way, is not to be thought of as only the ordinary loop made relative to the background of stars, but rather as a loop made relative to the leafless branches of the old tree at the south end of my garden, as viewed each evening from the same spot, at the time of sunset. The hourly changes of position of any object may be judged from the seventeen little arrows showing the track of an equatorial star at sixteen hourly intervals, and some planetary positions are marked below the eastern horizon. Jupiter and Saturn are nearly as sedate as fixed stars.

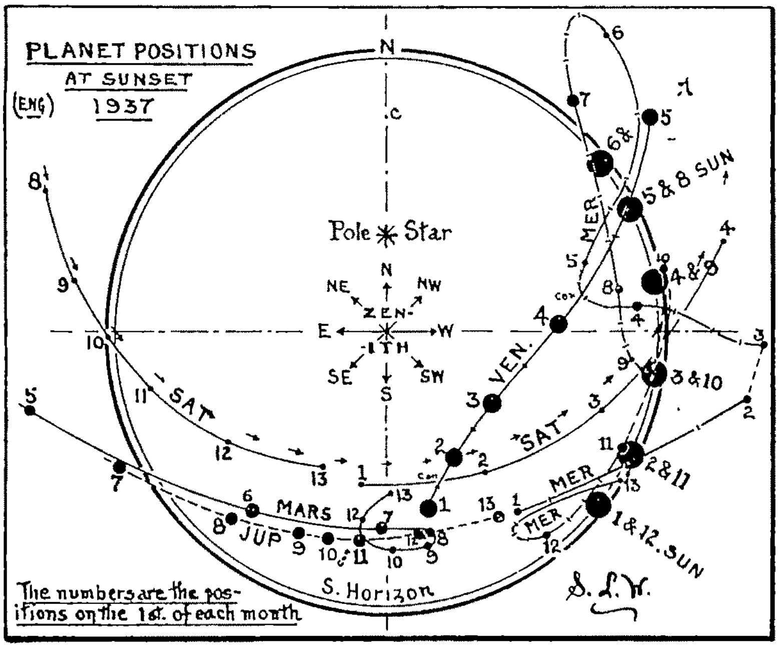

Fig. 1.

About the middle of January the planets Venus and Saturn appeared close together, and the same will be true of Venus and Mercury in April. Mars and Jupiter are to be so close together at the end of October that the one spot numbered 11 is allowed to mark the position of both.

Latent Heat of Evaporation of Liquid Helium

THE letter of Dr. J. Newton Friend in NATURE of December 26, 1936, on this subject raises interest in his equation. I have tested it with the following results:

As many know, the variation of the coefficient of viscosity of a liquid with temperature can often be expressed—over a short range at least—by an equation of the type

$$\log_e \eta = A + \frac{B}{T} \quad . \quad . \quad . \quad . \quad (1)$$

Taking therefore Dr. Newton Friend's equation for latent heat and casting it in the form

$$\text{Molar } L = 4R \frac{T_1 - T_2}{T_1 T_2} \log_e \frac{\eta_1}{\eta_2} \quad . \quad . \quad . \quad . \quad (2)$$

we get by inserting equation (1)

$$\text{Molar } L = 4R \frac{T_1 - T_2}{T_1 T_2} B \left(\frac{1}{T_1} - \frac{1}{T_2}\right) = 4RB \quad . \quad . \quad (3)$$

which looks simple enough.

Taking the viscosity results on helium liquid I obtained in Toronto and plotting them over the range 3·5°–4·2° K. (I restrict myself to temperatures not far from the boiling point, 4·2° K.), I find:

$$\log_e \eta = A + \frac{9}{T}$$

There is no point at present in evaluating A. Substitution in equation (3) gives a value for the molar L as 72 calories. This is equivalent to 18 calories per gm.

If, however, we use the data obtained at Leyden, the latent heat of vaporization of liquid helium 1 is of the order of 5 calories per gm. (Reference to the Leyden entropy diagram of helium shows an increase of entropy of 1·2 units per gm. when liquid helium 1 evaporates at 4·2° K., and 1·2 × 4·2 = 5 calories very nearly).

Therefore whether we consider Dr. Newton Friend's result or the value I quote above as being more correctly obtained by his equation, we see that the agreement with the correct value is not good. Hence his equation must be in error.

JOHN SATTERLY.

Department of Physics,
University, Toronto.
Jan. 19.

I AM grateful to Prof. Satterly for directing attention to the discrepancy. Accepting 5 × 4 = 20 as the molar latent heat of evaporation of helium, the value 31·3 calculated with the aid of the Clausius-Clapeyron equation is certainly wide of the mark; so is 36·2 which I calculated from my equation using Prof. Burton's data. But as my equation was derived on the assumption that the Clausius-Clapeyron equation holds, clearly if the latter fails the former may be expected to do so also.

Both equations have, however, been found to give very satisfactory results with a large number of substances. Assuming the vapour pressure and viscosity data for liquid helium are correct, instead of suggesting that the equations "must be in error", would it not be better to suggest that helium is abnormal? That such may well be the case is evidenced by the curious fact that liquid helium II is much more fluid than liquid helium 1, despite its lower temperature, as Prof. Satterly has himself pointed out elsewhere[1]. It would be interesting to ascertain the absolute cause of this discrepancy.

Magnetic and Electrical Dimensions

IN NATURE of January 9, in a review of Dr. Lanchester's book on "The Theory of Dimensions", Prof. G. W. O. Howe devotes a portion of his review to the dimensions of electrical entities and his own views upon the same, and criticizes adversely a paper of mine upon this subject, which Dr. Lanchester had printed in full in an appendix in his book.

Prof. Howe proposes to write the fundamental equation of electromagnetism

$$f = \mu \,.\, \frac{ids}{r^2} \,.\, ids,$$

and he evidently intends μ to be the permeability, because he states: "The classical formula $f = mm'/\mu r^2$ is merely the above formula wrapped in mystery".

It will be noticed that in Ampère's classical equation given above, Prof. Howe has substituted μ for $1/A'$. He does this without any explanation or justification, unless, since $c^2 = A'/K$, it is merely to maintain the expression $c^2 = 1/\mu K$, whereas the full expression is $c^2 = A'/K = A^2/\mu K$, A, A', μ and K being the four fundamental constants in the classical theory. Now Maxwell assumed A' to be an undimensional constant numerically equal to unity, and this has been the established practice, hence K has the dimensions $1/V^2$ and even if $c^2 = 1/\mu K$, μ must be undimensional, a conclusion to which Prof. Howe objects.

With regard to Prof. Howe's mystery and his further reference to "such a fictitious complexity as a permanent magnetic point pole of unit strength", is there any more in this than the conventional application of our standard method of dealing with a system of distributed forces in a case where the forces are both attractive and repulsive, by finding the centroid of each system and calling these points the poles of the magnet? The resultants through the poles give the same magnetic moment as the magnet possesses, and the historical choice of the unit pole was a very natural one. How else would it be possible to deal with the interaction of magnets? It is a common physical laboratory experiment to determine the equivalent poles of a long bar magnet by means of an exploring coil or vibrating needle. Other "fictitious" complexities are found useful in other branches of science in order to make very abstruse problems easily tractable, such as point sources and sinks in hydrodynamics. Think of Rankine's work on streamlines by this method.

If magnetic forces are due to electric currents, then the two standard equations $f = ids \,.\, i'ds'/A'r^2$ and $f = mm'/\mu r^2$ must be co-dimensional, and the simplest solution is $m = iL$ and $A' = \mu$ dimensionally. No objection either physical or mathematical has yet been offered to this solution, which eliminates from electrical science that great bugbear, the dual system of dimensions, and no sacrifice is required in adopting it.

I would remind Prof. Howe that one International Committee has already recommended that μ is to be considered a dimensional entity, also that the final decision is to be made this year.

JAMES B. HENDERSON.

38 Blackheath Park,
London, S.E.3
Feb. 11.

IN reply to Sir James Henderson, I can only say that I was under the impression that I had given ample explanation and justification for introducing only one magnetic constant of space. If ferromagnetism is due to orbital movement of electrons, that is, to electric currents, then I cannot believe that the forces between magnetic poles involve one property of space and the forces between current-carrying conductors another property. I intended μ to be exactly what I stated in the review, namely, the space constant which makes the formula for the force between electric currents (or magnets) dimensionally and numerically correct, just as $1/K$ is introduced in the formula for the force between charges, and G in the gravitational formula.

I agree that point sources and sinks are excellent mathematical tools and that the unit pole is a very useful conception, but having invented the conception, let us not look to it as an oracle and expect it to answer questions on the ultimate realities of electromagnetism. As I have said elsewhere[1]: "the greatest danger in this subject is that of overlooking the fact that, having put various ingredients into the hopper and turned the handle several times, the result has not dropped from heaven but has come out of the machine and contains all the assumptions that were put in". For this reason I am not impressed by the statement that on certain assumptions "μ must be undimensional" or that the simplest solution of some equations is that $A' = \mu$ dimensionally.

With reference to the equations "$f = ids \,.\, i'ds'/A'r^2$" and "$A' = \mu$ dimensionally", to which Sir James Henderson says "No objection either physical or mathematical has yet been offered", seeing that this is equivalent to writing $f = ids \,.\, i'ds'/\mu r^2$ with μ in the denominator, I can only express my surprise that such a suggestion is put forward seriously.

I cannot understand why Sir James Henderson should remind me of the well-known fact that one International Committee has already recommended that μ is to be considered a dimensional entity. This is surely what I maintained in the review. I was under the impression that he was trying to maintain the contrary opinion. I am in entire agreement with the recommendation of the Committee and with Rücker, who pointed out the advantage of "not suppressing the secondary fundamental units such as μ and K" by "arbitrarily assuming that some one of the quantities involved is an abstract number".

Supraconductivity of Lanthanum

WE have investigated the magnetic behaviour of lanthanum below 10° K. The metal was kindly lent to us by Prof. F. M. Jaeger of Groningen; the analysis was given as lanthanum 98 per cent, iron 1 per cent and traces of carbon, silicon, aluminium and magnesium. Two lumps of irregular shape were tested by methods described previously[1, 2]. Strong diamagnetic susceptibility, which could be destroyed by a magnetic field, showed that the specimens became supraconductive. After supraconductivity had been destroyed by a magnetic field, the magnetic flux threading the specimens 'froze in' when the field was lowered again. The formation of such a supraconductive 'sponge' was to be expected in a specimen containing 2 per cent of impurities[3].

The transition point in zero field was determined by the decrease of the 'frozen in' magnetic dipole with increasing temperature[4]. The transition point was found to be 4·71° K. The threshold values, that is, the field strengths at which the last trace of supraconductivity disappeared, were found to be very high (steepness of the threshold curve more than 1,000 gauss per degree). The specimens behaved in all respects similarly to the samples of tantalum investigated by Mendelssohn and Moore[1].

So far, supraconductivity has been observed in all metals in Groups II*b*, III*b*, IV*a*, IV*b* and V*a* of the Periodic Table (except germanium, which is cubic like grey tin, and protoactinium, which has not been tested) but in no other group. The supraconductivity of lanthanum (Group III*a*) makes it probable that some of the other metals of this group also (scandium, yttrium, actinium) will become supraconductive. The question arises also whether the rare earths between lanthanum and hafnium will show supraconductivity. It has to be remembered, however, that the rare earths, owing to their incomplete *N*-shells, have strong magnetic moments which may make supraconductivity impossible. From this point of view, the element 71 (where the *N*-shell is completed) is the one in which supraconductivity is most likely.

Dr. Seeber in South Africa

IN connexion with the study of South African freshwater fishes, it is of interest to ascertain particulars about Dr. Seeber, after whom two fishes were named by Gilchrist and Thompson. Apparently Dr. Seeber corresponded with these authors about the years 1909-11, but I can obtain no information as to who Dr. Seeber was, where he lived or was stationed, or where he travelled in South Africa. The Medical Register and other local sources have failed, and this request is issued in the hope that one of the many readers of NATURE may have known Dr. Seeber. Any facts bearing on his residence or activities in South Africa will be welcome.

Points from Foregoing Letters

MISS E. W. HUME reports the preliminary results of an investigation on vitamin A standards, undertaken by the Accessory Food Factors Committee with the help of numerous collaborators. It appears that the discrepancies previously reported in the case of 'concentrates' have been due to unsuspected deterioration in the course of biological tests. The factor for converting results of spectroscopic tests into international units is found to be 1,470, with a range of individual values of 1,400–1,700. The previously accepted value of 1,600 recommended by the International Conference of 1934 is, however, retained for the time being.

According to investigations described by Holger Klingstedt, the behaviour of the sex chromosomes at meiosis indicates a closer relationship between sections of the Megaloptera and true Neuroptera than exists within these orders. The old distinction between them may therefore be unsound, as newer morphological and palæontological evidence also indicates.

The reversible behaviour of the blue and green solutions obtained by treating ascorbic acid (vitamin C) with phosphomolybdic acid is described by Prof. N. Bezssonoff and Mélanie Woloszyn. The authors consider this as further proof of the 'duality' of the reversibly-oxidized form of ascorbic acid and, by comparison with the behaviour of other organic compounds, conclude that the dienol group of the vitamin C molecule is polarized.

The identification of tyrosine by means of X-ray spectrograms in diseased pedipalps (arachnids related to the scorpions) is reported by F. A. Bannister. The tyrosine occurs in the form of radiating needles in museum specimens which have been affected by a fungus disease (actinomycosis).

A chemical examination shows that the ink used for the letters found on the biblical site of Lachish was of mixed iron and carbon type. A. Lewis has, in addition, investigated other ancient documents and concludes that iron inks, probably in combination with a gall or tannin extract, were frequently used in antiquity.

Curves based on the critical penetration frequency of radio waves, indicating a sharp increase in the ionization of the E_1 and E_2 regions of the upper atmosphere during the period of maximum intensity of the Leonid meteoric showers in November 1936 are submitted by J. N. Bhar. The ionizing power of the meteors appears to be effective in the region where they are visible to the naked eye (between 165 km. and 70 km.).

A new value for the ellipticity of the earth and that of the moon's equator, based on a corrected value for the moon's perigee and node, calculated by Prof. W. W. Brown, is given by Dr. Harold Jeffreys.

Prof. J. Sattorly points out that the value of the molar latent heat of evaporation of helium calculated from data on viscosity and vapour pressure, according to Dr. J. Newton Friend's formula, does not agree with the experimental value, and concludes that the formula is incorrect. Dr. Newton Friend suggests that, since the formula applies to a large number of substances, one may assume that liquid helium behaves abnormally.

Research Items

The Katanga Skull

THIS human skull belonging to a skeleton found in 1918 in some old native workings in the mine of Kambove (Katanga) in the Belgian Congo, has been made the subject of a study by Dr. Matthew Young of University College, London (*Mém. Musée Roy. d'Hist. Nat. de Belgique*, (2), 5). The skull is complete, with the lower jaw. It is undoubtedly of negro type, though showing signs which suggest admixture Unfortunately, the remainder of the skeleton was not preserved. Although stained green with malachite, it shows no signs of mineralization to any appreciable degree. The specimen is of moderate length, very narrow, with a notable post-orbital constriction, and relatively high with a well-arched vault. The forehead is fairly rounded and shows the median eminence characteristic of the negroid type, though there are distinct indications of frontal eminences. The supraciliary ridges are fairly prominent. The temporal ridges are strongly developed, which is said to be a negroid feature. They appear to be more convergent than usual. The face is long, the nasal bridge excessively flat. The nasal aperture is relatively wide. Prognathism is moderate, and the lower jaw robust. The lower central incisors had been extracted at an early age. The skull is adult and probably male. It most closely resembles the Teita series from East Africa collected by Dr. Leakey, except in regard to the length of the face and especially of the alveolar portion. In this respect, it resembles two Nuba females from South Kordofan. A similar type of unusually long face and development of the alveolar region, accompanying an exceptionally high palate, is seen in Leakey's Nakuru and Elmenteita types, which have been compared with the Oldoway skull. These are usually considered to be Hamites, while Keith regards Oldoway as proto-Hamite. The Katanga skull then is a negro of recent date, probably not later than twelfth century, and is more nearly allied to the East than the West African type. It may be the remains of a slave captured at some distance from the Katanga

Mule Deer of the Pacific Region of America

As a result of the examination of 602 specimens of *Odocoileus*, supplemented by the studies of former investigators, Ian M'Taggart Cowan finds that two species only inhabit the Pacific coastal region of North America—the white-tailed deer (*O. virginianus*) with two geographical races, and the black-tailed deer (*O. hemionus*) with nine. Complete intergradation was found between the latter and *O. columbianus*, formerly regarded as a distinct species (*California Fish and Game*, 22, 155; 1936). The monograph is a thorough one, but we can refer here only to two points of general interest. The pigmentation, particularly of the tail, shows great variation, and each colour grade is generally associated with a more or less uniform set of environmental conditions, but over the whole area the intensity of the coat colour seems to be related to the humidity of the environment. The races living in the humid coastal region have the darkest pigmentation, the desert forms the lightest; and in these respects the coloration agrees with what has been found in several other mammals and birds. The second point is that the races of the mule deer conform to the general truth known as Bergmann's law, that individuals of races inhabiting colder localities are larger than those of races inhabiting the warmer regions. Not only is this so, but also the northern races, as well as being larger than the southern, display greater sexual dimorphism in size of body.

Pinus radiata in New Zealand

A LEAFLET (No. 28. N.Z. State Forest Service, December 1936) has been recently issued dealing with the terminal hypertrophy in *Pinus radiata* in relation to frost damage. It is based on researches by Mr. T. T. C. Birch. Hypertrophied terminals are distinguishable from a normal leading shoot by the following characteristics: (1) length of terminal, from last whorl to apex, exceeds 4 ft. and occasionally reaches 12 ft. or more; (2) epicormic shoots and five-needle fascicles are often associated with the condition; (3) the larger hypertrophied terminals do not necessarily represent one year's growth, two layers of wood frequently occurring in the basal portions, without lateral branches; (4) abnormal turgidity and brittleness, primarily due to the large proportion of medulla in the shoots. As might be expected, hypertrophied terminals rarely escape some form of climatic injury, and owing to their brittle nature, many of those projecting above the normal crown-level of a stand, are broken or damaged by wind. Frost also is responsible, both directly and indirectly, for a considerable amount of damage to hypertrophied terminals. Mr. A. D. McGavock, director of forestry, says in a note that "Mr. Birch is conservative when he describes this leader as 'occasionally reaching 12 ft. or more'. This is correctly stated if he refers to a single year's growth only; but similar growth in subsequent years is frequently superimposed on this, and lengths of up to 22 ft. without a single lateral branch have been measured. Such a condition in itself is undoubtedly a sign of ill-health in a tree; but seemingly because it is not due to any pathogen nor to any apparent mechanical injury, it has not, so far as I am aware, received any attention from forest pathologists".

Respiration in Tropical Fruits

THE extensive studies of changes during ripening in fruits in storage under English conditions carried on at the Low Temperature Research Station, Cambridge, are now being very usefully extended to the tropical fruits, at the equivalent research station in Trinidad. Drs. C. W. Wardlaw and E. R. Leonard have two papers dealing particularly with respiration in tropical fruits in the *Annals of Botany*, 50, 1936, which are also issued separately by the Imperial College of Tropical Agriculture (July 1936). Two points of general importance in these communications are the further support given to the importance of the oxygen concentration in the internal gas concentration in relation to the initiation of that period of maturation frequently described as the climacteric, and the new suggestion that the subsequent onset of senescence may be associated with the difficulty in the movement of oxygen into the interior of the fruit as a result of the changes in texture, etc., associated with maturity, which hinder the ready access of oxygen from the outside air. Considerable attention has been paid to the internal atmosphere in these studies, such hollow fleshy fruits as the papaw readily lending themselves to the necessary technique for sampling the internal gases.

A Halo-Spot of Tomatoes

THE prevalence of tomatoes covered with a number of silvery spots has been noticed on many occasions. Insects were thought to be the cause, but Dr. C. L. Walton has shown (*Gard. Chron.*, Jan. 2, 1937) that this is not so. The trouble appears when 'top-watering' to simulate rain is practised. Drops of water fall upon the fruit, and if a burst of sunshine occurs, they evaporate very rapidly, and the skin of the fruit is scorched. This kind of trouble is probably more widespread than is often realized, and the lens-shape of the drops may even cause necrotic spots or other puzzling symptoms.

Cordierite in Pegmatites from Japan

THE results of an important study of cordierite and its graphic intergrowth with quartz in Japanese pegmatites has been published by H. Shibata (*Jap. J. Geol. Geog.*, 205 ; 1936). The pegmatites are regarded, not as of purely igneous origin, but as syntectic products involving reaction with the invaded rocks. One from Sasago injects sandstone and slate ; in the central zone of graphic microcline-granite, rosettes of andalusite and intergrowths of cordierite and quartz occur. Another intrudes amphibolite of the Misaka Series (Higashidani). Soda diffused into the amphibolite, while reaction between magnesium silicate (from hornblende) and the pegmatitic liquid led to the crystallization of cordierite. In another example (Mujinazawa) cordierite also formed by reaction of magmatic material with hornblende. A zonal arrangement of minerals developed, with graphic intergrowths of cordierite and quartz in the intermediate zone. The analysed cordierites show large amounts of iron, manganese and soda. The author has systematized the physical and chemical properties of cordierites from all parts of the world. The various relationships between optical properties and chemical composition are summarized in a series of tables and diagrams.

Geographical Distribution of Deep-Focus Earthquakes

A RECENT paper by Messrs. B. Gutenberg and C. F. Richter (*Bull. Seis. Soc. America*, 26, 341 ; 1936) contains some interesting notes on the distribution of deep-focus earthquakes. Those with focal depths of about 100 km. occasionally occur in nearly all the seismic regions of the globe. Others with depths of about 200 km. are frequently found in regions, such as the eastern Mediterranean and the Hindu Kush, where there is at present no evidence of very deep foci. So far as is at present known, earthquakes originating at the greater depths (400-800 km.) are confined to a few regions adjoining the Pacific Ocean, such as Kamchatka and the Kurile Islands, Japan, the East Indies and western South America. In Japan and South America, the deeper the foci, the farther removed as a rule are the epicentres from the ocean basin. With regard to the origin of such earthquakes, the most probable conclusion at present is that normal and deep-focus earthquakes are caused by the same forces, which may act near the surface or at great depths.

Measurement of Upper Winds

THE measurement of upper winds by means of pilot balloons is the subject of a recent publication (M.O. 396) of the Meteorological Office, Air Ministry (H.M. Stationery Office, 1936. 1*s*.) This method of measuring upper winds has been in use for many years, and has developed greatly as the demands of aviation for information about upper winds have increased. It depends upon observations of the elevation and azimuth of a small balloon that ascends at a nearly constant speed and is carried horizontally by the wind at its level. These angles may be measured by a single theodolite, and the wind is then calculated on the supposition that the rate of ascent is strictly constant. Alternatively, two theodolites may be used at a known distance apart, or a tail of known length may be attached beneath the balloon and the angle subtended by the tail be measured by a graticule at the focus of a single theodolite. Each of these alternatives does away with the need for assuming a constant rate of ascent, and in expert hands provides reasonably accurate information about the upper winds. In M.O. 396 the practical details are set out, including the method of filling the balloon and giving the necessary free lift, the setting up of the special theodolite and the working out of the speed and direction of the wind from the observed angles. A full-sized drawing of the special slide rule used for these computations is included.

Air Conditioning in Modern Buildings

IN a paper read on February 19 by Mr. E. R. Dolby to the Institution of Mechanical Engineers the whole question of ventilation and air conditioning in modern buildings is discussed. It has been stated that the ideal condition of the air is that of a hillside on a bright spring morning. This is taken to mean that the air is free from dust, odours, etc., that the temperature should be moderate, say, 60° F., the humidity about 50 and that there should be a bright atmosphere with slight, but not excessive, movement. In the ideal suggested, the carbon dioxide in the air should be restricted to not more than 6-7 parts in 10,000, as compared with 4 parts in 10,000 in the external air. Mere ventilation as, for example, the system used in coal mines, where a large volume of external air is passed into the mine and the contaminated air in the mine extracted, differs from 'conditioned air' ventilation as now used in houses, shops, factories, theatres and ballrooms. In the latter case the vitiated air is evacuated and replaced by air so treated that dust, fog, deleterious gases and odours are eliminated. The temperature of the incoming air is raised or lowered and its humidity is suitably modified. At the same time the conditioned air must cause no unpleasant draughts. The maximum air velocity of the delivered air, for comfort, in sedentary occupations is assumed to be about 2 ft. per sec. In large works, hotels, exhibition buildings in which a kitchen or canteen forms part of the establishment, the installation of a separate ventilating and air conditioning plant is well worth considering.

The Beta-Ray Disintegration

A DISCUSSION on the β-type of nuclear transformation was held by the Royal Society on March 4. Papers were read by Prof. C. D. Ellis, Dr. J. D. Cockcroft, Dr. R. Peierls and Dr. H. O. W. Richardson; a number of other experimental and theoretical workers took part in the discussion. The main centre of interest seemed to be in the correctness or otherwise of the neutrino theory.

Prof. C. D. Ellis, in his opening address, gave a brief account of the development of our knowledge of the β-ray transformation in recent years. As is generally known, the fundamental difficulty is that the electrons (or positrons) are emitted with a continuous energy distribution although there must be a constant difference between the proper energies of the initial and final nuclei. This anomaly could be explained either by abandoning the conservation laws, or as suggested by Pauli, assuming that another uncharged particle, the neutrino, is emitted in the transformation and shares the available energy with the electron. This latter alternative is now generally favoured.

The neutrino has been given a spin equal to that of the electron, to enable angular momentum to be conserved in the transmutation; and a mass, which if not zero, is only of the same order as that of the electron. A particle with these properties would be very difficult to observe directly, and in fact the many attempts which have been made to detect the neutrino by any ionization it produces have all failed. The hypothesis can at present only be tested by its success in accounting for the features of the β-ray decay.

One consequence of the neutrino hypothesis can be seen without any detailed theory. The β-ray spectrum should have a definite upper limit at which the neutrino is emitted with zero kinetic energy, and this end point should be given by the difference between the masses of the particles before and after the transmutation. If these predictions were not fulfilled, the neutrino theory would have to be abandoned.

The evidence on this point was discussed by Dr. Cockcroft. In about six cases of β-transformation among the light elements, the end point of the spectrum is known with fair accuracy, and the difference between the initial and final masses can be obtained from other transmutations in which energy is certainly conserved. The results are sufficiently definite to show that the mass difference cannot be equated to the *mean* energy of the β-ray spectrum, but its identity with the experimentally determined end point is still rather uncertain. However, even this is very useful evidence. It is known that the total energy emission as measured in a calorimeter corresponds to the mean energy of the spectrum. As the change in mass in the transmutation is certainly greater than this, there is a definite surplus of energy which must either have disappeared or have been carried out of the calorimeter in the form of neutrinos.

Further data on the identity of the end point of the spectrum and the mass difference of the initial and final nuclei would be very important, as this is one of the few points on which the neutrino hypothesis is capable of being disproved. However, the determination of the end point of the spectrum is a matter of some difficulty, because the intensity approaches zero very slowly with increasing energy. The actual end point must be found by extrapolation. Here a theory of the form of the β-ray spectrum would be very useful. Unfortunately, the most successful theory, that of Uhlenbeck and Konopinski, disagrees with the observed spectrum just in this region, and extrapolations based on it give values for the end points which appear to be too high. In these circumstances, all that can be said is that the experiments do not disagree with the value for the end point given by the mass change in the disintegration.

The detailed mathematical development of the theory enables it to be compared with other experimental data. We may expect the theory to predict the form of the β-ray spectrum and how it depends on such parameters as the total energy released and the change of nuclear spin in the transmutation. Also the theory should give the value of the total probability of disintegration, or the decay constant. The general case of β-decay is one in which the final nucleus may be formed in one of a number of excited states. The β-ray spectrum is then built up of a number of partial spectra, each with a different end point and intensity. In examining such a spectrum, the experimenter depends on theoretical guidance on these points.

The theoretical aspects of the problem were dealt with by Dr. Peierls. The theory is based on the analogy between the transition of an atom between two stationary states with the emission of a light quantum, and the transmutation of a neutron into a proton with the emission of an electron and a neutrino. A remarkable consequence of this point of view is that it should be possible for a nucleus to be transformed by capturing one of its K electrons and emitting a neutrino—a new type of transmutation which has not yet been observed.

To proceed further, the theoretical worker has to assume some form of interaction between the neutrino and the heavy particles which give it birth. Here he has little to guide him but the demands of relativistic invariance and his æsthetic sense. The most simple and natural assumption was made by Fermi, but this led to a form of the β-ray spectrum which was definitely too symmetrical about the mean energy. Konopinski and Uhlenbeck remedied this by using a form of interaction which depended on the velocity of the neutrino as well as on its position. At first they appeared to have been very successful. Experiments with the large sources of light radioactive elements now available in the United States gave very satisfactory agreement with the new theory. A more detailed study has since shown that though the main part of the spectrum was given correctly, the high- and low-energy regions required modification. The evidence on this point was discussed by Dr. Richardson, who showed that whereas fair agreement with experiment was obtained for the low-energy part of the spectrum when account was taken of the Coulomb forces on the electrons, the Konopinski-Uhlenbeck theory gave too high an intensity for the high-energy electrons, in some cases by a factor of fifty.

Attention has therefore been turned to other possible modifications of the theory. A very wide choice seems to be possible, so that the theory could be made to fit almost any form of the experimental spectrum in several different ways. This elasticity is perhaps an advantage, in that there is no immediate danger of our being forced to abandon the neutrino theory and therefore the conservation laws, but it destroys much of the heuristic value of the theory. For example, although the β-transmutations can be classified into two groups, corresponding to the two Sargent curves connecting the decay constant with the energy of the end point, it is not known how this classification is connected with the change of nuclear spin in the transmutation.

In conclusion, the general impression given by this discussion was that although the neutrino theory is probably capable of explaining most of the features of the β-ray transmutation, it scarcely does so in the natural and unforced way which alone would reconcile the physicist to an unobservable particle. However, it remains a working hypothesis useful in directing attention to the points which still require experimental work, and in collating the data already obtained.

A. NUNN MAY

Lightning

AN instructive paper on lightning was read on January 7 by B. L Goodlet, of the Metropolitan-Vickers Electric Co., Ltd., to the Institution of Electrical Engineers. He discussed lightning first as a physical phenomenon and then gave the elementary theory of direct strokes to transmission circuits. He began by saying that although "Lightning" was the title of the Kelvin Lecture given seven years ago, yet the progress made during the last seven years is at least as great as that made during the previous seventy. He awarded due credit to the early pioneers, but modern research on the subject has been so intensive in high-tension laboratories, in the upper atmosphere and in connexion with the tens of thousands of miles of high-tension overhead wires now in continuous operation, that the modern research workers have large sources of experimental data from which they can test theories widely accepted in recent years.

The cumulo-nimbus cloud, or thundercloud, differs from the ordinary rain cloud in having greater vertical dimensions and in the existence of powerful upward air currents. Its formation is associated with convectional instability of the atmosphere, the separation of the electric charge being effected by the resulting upward currents of air. Lightning strokes usually discharge negative electricity into the ground, and consist of a preliminary 'leader' stroke from cloud to earth followed by a powerful return stroke from earth to cloud. Schonland found by means of a Boys camera that each flash is initiated by a streamer which shoots rapidly downwards from the cloud towards the ground, but becomes extinguished before it has travelled more than a fraction of the total distance. About 50 microseconds later, a second streamer follows closely on the track of the first and elongates the channel a little farther. This goes on until an ionized channel is blazed all the way from cloud to earth. The rate of growth of the channel is of the order of 100 kilometres per second.

The maximum current at the ground end of a lightning flash is deduced from the intensity of the magnetic field produced in the vicinity of transmission towers and lightning conductors struck by lightning. About 24,000 magnetic detectors were distributed over the lines of various German electric power companies in 1934. The results showed that the most frequent value of the maximum stroke current lay between 30,000 and 40,000 amperes. Currents greater than 100,000 amperes occur very rarely In 97 per cent of the cases recorded, the cloud discharged negative electricity to the earth. Presumably therefore the base of the cloud must have been negative. Similar results have been obtained in the United States.

The question has often been discussed as to whether certain localities receive an abnormal proportion of lightning strokes. The evidence in favour of localization of lightning flashes comes mainly from the records of electricity undertakings. It has been found, for example, that a certain 80 km. line received 43 strokes, of which 26 fell on one section 6·3 km. in length. Investigation showed that this section of the line was traversed by underground springs. A study of available data has convinced the author that the existence of 'danger spots' struck more frequently for a given storm exposure is a fact.

Some interesting lightning problems occur in connexion with aircraft. Ten cases are known of British aeroplanes having been struck by lightning. In nine out of the ten cases, the wireless aerial was hanging down and was damaged. Moored kite balloons are particularly troubled by phenomena of this nature. When an aeroplane or an airship is flown through a thundercloud, the metal parts of the machine, unless bonded together, acquire very different potentials. Shocks are experienced by persons inside the aircraft when they touch and when they leave go of metal objects.

The earth currents caused by lightning can be a source of great danger. If a current of 50,000 amperes enters the soil at a point and spreads out uniformly in all directions, the voltage drop on the surface as we go away from the point may be very large even at some distance away from the point. The voltage between two points on the earth separated by the length of an animal's stride may be quite sufficient to pass a lethal current up one leg and down another.

The second part of the paper was more technical, being concerned mainly with direct strokes to transmission circuits. In this case rather more than half the direct strokes to a line fall on the conductors in the span between the towers. The final potential of an insulated conductor so struck is probably never less than 2 million volts, and may be sixteen times as great The insulator impulse spark-over voltage of the most heavily insulated overhead line yet constructed is of the order of 2½ million volts. Wooden poles give additional insulation to earth, but cannot be relied on to withstand more than 100–150 kV. per foot. It seems highly probable, therefore, that practically every direct stroke to a live wire will produce some kind of flash-over.

Hence it is necessary to prevent direct strokes or to render flash-overs innocuous. The first can be done by an overhead earthed wire, which proves to be a reasonably effective interceptor; but in places where special protection is required, two earthed overhead wires should be used. In order to secure easy entrance for the current in dry soil, many modern lines are equipped with a 'counterpoise'. This consists of a length of bare cable buried in the ground and attached to the foot of the tower. Each circuit of the new Boulder Dam line in America is equipped with two parallel counterpoises, continuous from tower to tower.

The alternative to lightning-proof construction of the line is to ensure that lightning flash-overs on the line do not interrupt the supply. The best known method of doing this is to use a Petersen coil, which is in general use on the Continent but is less popular in Great Britain and the United States. Alternative methods were also mentioned. In the author's opinion, these methods will prove more popular than the overhead earthed wire, as they are much cheaper. Arc rupturing devices and lightning arrestors can be installed easily on existing unsatisfactory lines.

University Events

BIRMINGHAM.—Dr. Henry Pratt Newsholme, Medical Officer of Health for Birmingham since 1927, has been appointed to the chair of hygiene and public health in succession to the late Sir John Robertson.

CAMBRIDGE.—Prof. E. D. Adrian, Fellow of Trinity College, Foulerton professor of the Royal Society, has been elected as from October 1 to the professorship of physiology which will become vacant by the retirement of Sir Joseph Barcroft.

The subject for the Sedgwick Prize for the year 1940 is: "The Influence of the Idea of Evolution on some Branch of Geological Studies". The essays must be sent to the Registrary on or before October 1, 1939.

The examiners consider that the following essays submitted by candidates for the Smith's Prizes and Rayleigh Prizes are of distinction: H. M. Cundy (Trinity College), "Motion in a Tetrahedral Field"; E. R. Love (Trinity College), "Riemann-Stieltjes Integrals"; H. R. Pitt (Peterhouse), "Tauberian Theorems". The Smith's Prizes have been awarded to E. R. Love and H. R. Pitt and a Rayleigh Prize to H. M. Cundy.

GLASGOW.—Prof. G. G. Henderson, regius professor of chemistry, has sent in his resignation, to take effect from October 1.

Dr. J. Bassil Rennie has been appointed wholetime lecturer in the practice of medicine.

SOUTHAMPTON.—Dr. N. K. Adam, research chemist in Imperial Chemical Industries, Ltd., has been appointed professor of chemistry in University College.

Science News a Century Ago

Birds of Paradise of the Arru Islands

AT a meeting of the Royal Geographical Society held on March 13, 1837, a communication by W. S. Earl was read entitled "On the Key and Arru Islands". The Arru Islands, the author said, were about forty miles south-west of Papua, or New Guinea, and about a hundred miles to the north-east of Timor Laut. The Keys were a smaller group about thirty miles to the westward of the Arrus. The islands were small but closely grouped. Much commercial intercourse prevailed between the islands and the neighbouring coasts, the chief exports being tortoise-shell, bees-wax, ambergris, edible birds' nests and birds of paradise. The last were found in great numbers on the Arrus and the coasts of New Guinea. They were especially valuable, and from the numbers sent to Singapore appeared to be inexhaustible.

Valentyn, a Dutchman who wrote on the East in 1702, described seven varieties of these beautiful birds, while Le Vaillant, and later Guimard, gave descriptions of them. They were exported in great numbers to Arabia and Persia. Francois Valentyn or Valentijn, who was born in 1666 and died about 1725, was a protestant minister at Amboina, Banda and other places.

The Zoological Society

VARIOUS papers were read at the meeting of the Zoological Society held on March 14, 1837, one of them being by Darwin on the *Rhea Americana* and the newly discovered species, in which he described its mode of swimming, a fact unnoticed by earlier writers, but which he had witnessed in two instances. Their progress through the water was slow, very little of the body appearing above the surface, the necks being extended slightly forward. According to the Guachos, the males carried out incubation and not only hatched the eggs, but also attended the young until they were able to provide for themselves. Several females laid in one nest and the number of eggs deposited by each female during the season was from forty to fifty, or according to Azara, from sixty to seventy.

Physical Science in the University of Edinburgh

No one did more to further the study of physics in Scotland a century ago than J. D. Forbes, who instituted a complete working system of examining for degrees in arts in the University of Edinburgh by means of printed papers. His letters frequently contained references to his efforts to stimulate an interest in natural philosophy, and writing on March 15, 1837, to Airy, he said:

"I have been exceedingly busy, and not very well, which have been the causes of my silence. Among other occupations I have had to read five essays, which I have received in competition for a medal I proposed on the Undulatory Theory of Light, a new subject in Scotland, which I am delighted to find has stirred up our youth, and I have got some really respectable compositions. This is a proof to me that things are mending, and that exertion, private and personal, is not thrown away, even where public sympathy or support is not to be looked for.

"I have not abandoned my polarized heat, but have been much driven about this winter. I have got twelve thermometers sunk in different soils from three to twenty-six feet deep, to measure conduction."

Anniversary Meeting of the Statistical Society

At the anniversary meeting of the Statistical Society held on March 15, 1837, the third annual report of the Council was read. In the report, suggestions were put forth for furthering the object of the Society, which was instituted "for the purpose of procuring, arranging and publishing facts calculated to illustrate the conditions and prospects of society". Reference was also made to the advancement of statistical studies. A Statistical Society had been established at Bristol, and the Statistical Society of Glasgow had commenced to publish its proceedings. In foreign countries the collections of statistics had advanced rapidly. The French Government, following the example of that in Great Britain. had published a volume of statistical tables; the Belgian Government had published a similar volume and a statistical journal had been founded in Sicily. The total membership of the Statistical Society at this time was 392.

Societies and Academies

Dublin

Royal Dublin Society, January 25.

Paul A. Murphy: A ten-year experiment on the spread of leaf-roll in the field. The extent of spread was determined in relation to weather conditions in a uniform experiment. Most infection took place in June. Wet Junes were always marked by least spread, due to direct repression of aphids. The reverse did not always hold, the effect of dry Junes being more complex, affecting differently aphids, parasites and plants. Most spread generally took place when the rainfall of the month was nearly normal.

K. C. Dixon: Some aspects of carbohydrate metabolism.

Paris

Academy of Sciences, February 8 (*C.R.*, 204, 385–456)

Alexandre Guilliermond, Fernand Obaton and Roger Gautheret: Presentation of a film on the mitochondria in plant cells. This film, which is believed to be first taken of plant cells, proves definitely a certain number of essential properties of mitochondria concerning which many cytologists have held different views.

Antonin Gosset and Ivan Bertrand: The treatment in man of peripheral nerve sections by medullary heteroplastic grafting. Details of three successful applications of the method.

Marc Krasner and Mlle. Britt Ranulac: A property of polynomials of the division of the circle.

Jacques Hadamard: Remarks on the preceding communication. A. Lienard and Khintchine have given independent solutions of the same problem.

Szolem Mandelbrojt: The principle of regularization of functions.

Georges Valiron: The curves of constant modulus of integral functions.

Chi-Tai Chuang: Some theorems of the directions of Julia and of Borel of meromorph functions.

Pierre Dive: A heterogeneous fluid mass in rotation with a given kinetic moment.

L. Cagniard: The propagation of movement in viscous media.

René Swyngedauw: A new theoretical expression concerning a pulley with a thick belt.

David Belorizky: Resolution of the nebular lines in the spectrum of Nova Herculis 1934.

Théodore Kahan: The theory of the deuton: proton-neutron interaction of exponential tendency.

Ernest Baumgardt: The absorption of ultrasound waves by benzene.

René Lucas: New properties of the thermal elastic waves of liquids.

Douchan Avsec and Michel Luntz: Electroconvective vortices in a liquid sheet.

Mlle. Marguerite Quintin: The potential of copper in solutions of copper benzenesulphonate.

Léon and Eugène Bloch: Structure of the spectra Sb VI and Te VII.

Léon Grillet: The enlargement of the green line (5461 A. Hg) in mercury vapour arcs under high pressure. The green mercury line has been taken as the most useful basis for many measurements. The radiation of two mercury lamps has been studied with a prism spectrograph and with a grating. It is shown that the definition of the wave-length of this line requires special precautions.

Mlle. Hoang thi Nga: The colouring matters of the anthracene group and their photo-sensible capacity.

René Audubert and Henri Muraour: The emission of ultra-violet radiation in the course of the slow decomposition of nitrides (hydrozoates). The slow decomposition of nitrides when heated is accompanied by an emission of ultra-violet radiation. It is relatively intense with the nitrides of sodium, potassium, lead and silver, but very slight with the calcium and barium salts.

Pierre Bonneman: Contribution to the study of the condensed phosphoric acids.

Victor Auger and Mlle. Nina Ivanoff: The study of some phosphates of the type $M_{II}(NH_4)PO_4$.

Henri Moureu and Georges Wétroff: The phospham of Rose. It is concluded that phospham is not produced in the reaction between ammonia and phosphorus trichloride.

Louis Royer: The relations which exist between the gneiss, granitic and rhyolitic rocks of Djebel Arous to the north of Ménerville (Algeria).

André Rivière: The rational interpretation of the sifting 'spectra' of sandy sediments and the geological signification of the diagrams.

Jacques Bardet, Arakel Tchakirian and Mlle. Raymonde Lagrange: The determination of lithium in sea-water. Description of the methods employed for concentrating the lithium from 200 litres of sea-water: the purity of the lithium chloride separated was verified spectroscopically. The quantity found was 0·17 mgm. of lithium per litre.

Paul De Graeve: The evolution of puric nitrogen in the course of germination.

Robert Brunet and Antoine Jullien: The principal elements of myocardiac architecture in the Lamellibranchs.

Raoul Lecoq and Roger Duffau: The influence of acute lack of food balance of glucidic origin on the composition of the muscle of the pigeon.

P. G. Charpentier, Maurice Doladilhe and Charles Morel: The antibody property of the viscous protein of hæmolytic sera.

W. Kopaczewski: Gel formation of the blood constituents.

Brussels

Royal Academy (*Bull. Classe Sci.*, 22, No. 10 ; 1936).

L. Godeaux : Construction of an algebraic surface of divisor three.

T De Donder and Y. Dupont : New theory of the dynamics of continuous systems (2).

J. E. Verschaffelt : The application of thermomechanics to electrochemistry.

E. De Wildeman : Variations of generic characters which are specific, or belong to varieties, in plants, and some of their consequences.

P. Fourmarier : Preliminary observations on slaty cleavage between Boscastle and Newquay, Cornwall.

T. H. J. Lepage : Geodesic fields of the calculus of variations (2).

D. S. Mitrinovitch : Asymptotic lines of a class of surfaces and linear differential equations of the second order belonging thereto.

L. Pasqualini : Conditions of convexity of a plane curve or of a surface.

M. Linsman : Remark on the singular points of real surfaces.

Mlle. G. Schouls : Application of affinity and quantum statistics to catalysis.

Z. M. Bacq : Poisons of the nemerteans.

W. Robyns : Phenomena of pleiomery and synanthy in *Salpiglossis sinuata* Ruiz and Pav.

J. de la Vallée Poussin : Stratigraphy of the old formations in the region of the Great African Lakes.

J. Thoreau, R. Breckpot and J. F. Vaes : The monazite of Shinkolobwe (Katanga).

(*Bull. Classe Sci.*, 22, No. 11 ; 1936).

P. Bruylants and J. Jennen : Maleic and citraconic nitriles.

R. Godeau : (1) A class of surfaces the asymptotic lines of which have a given differential equation. (2) Remark on the paper "Asymptotic Lines of a Class of Surfaces" by Mitrinovitch.

Mlle. G. Schouls : Deduction and generalization of Arrhenius's formula with the aid of affinity and quantum mechanics.

E. Ruppol : Ultra-violet absorption spectrum of maleic nitrile.

J. Jennen : Maleic and fumaric nitriles. Preparative details, chemical and physical properties.

M. Florkin : True plasmatic glycæmia of a selachian (*Scyllium canicula* L.).

L. Lison : Vital coloration of the nucleoles in the Malpighian tube in *Forficula auricularia* Linn.

Geneva

Society of Physics and Natural History, December 17.

F. Chodat and R. Levy : Edaphism of moraine soils.

E. Guyenot and K. Ponse : The action of the urine of the ovariotomized woman on immature and adult female guinea pigs.

E. Guyenot : The action of the urine of the ovariotomized woman on hypophysectomized female guinea pigs.

Moscow

Academy of Sciences (*C.R.*, vol. IV, No. 7 ; 1936).

P. Alexandroff : Affine transformations of enumerably infinite multiplicity.

N. Günther : An integral analogous to the integral of Fourier.

P. P. Lazareff, Z. V. Boulanova and M. R. Semenovych : Influence of the latitude of the observation point on the adaptation in peripheral vision at different ages.

P. P. Lazareff and T. N. Čiževskaja : Change in the adaptation in peripheral vision with altitude above sea-level.

A. V. Lugovoj : Effect of short radio waves upon the life activities of cockchafer larvæ.

S. A. Neufach : Fate of glutathione introduced into the blood *in vitro*. Reduced glutathione can scarcely be detected in blood after 30 minutes.

V. Karasik and M. Lichačev : (1) Comparative biological activity of aromatic and heterocyclic arsonium bases. (2) The influence of the anion of dimethylphenazarsonium hydroxide salts on their biological activity.

A. P. Verner and A. A. Kovalev : The problem of the nitrogen-fixing power of *Bacterium radicicola*. The presence of bios is necessary for the reproduction of *B. radicicola* and for the accumulation of nitrogen by it.

N. A. Iljin : Homologous series in the phenogenesis of pigmentation.

B. S. Iljin : A new goby from the Caspian Sea, *Gobius nonultimus*, sp n. (Pisces, Gobiidæ).

A. A. Studitskaja : Formation of osteoclasts in cultures of skeletogenous tissue.

L. S. Berg : *Teleopterina*, n.g., a highly organized Acanthopterygian from the Carboniferous of North America.

Washington, D.C.

National Academy of Sciences (*Proc.*, 22, 673–713, December 15).

G. S. Avery, jun., P. R. Burkholder and Harriet B. Creighton : Plant hormones and mineral nutrition. Experiments with shoot tips of sunflower and tobacco plants grown in sand culture suggest that growth hormone production is unaffected by relative deficiencies of the common elements, or by variation of osmotic pressure of nutrient solution, but is most abundant in plants provided with a high concentration of nitrogen and scarcely detectable in absence of this element.

W. E. Castle : A simplified explanation of Bellamy's experiments concerning sex determination in tropical fishes.

M. J. Buerger : (1) The kinetic basis of crystal polymorphism. For a given temperature, there is a preferred vibration mode for the aggregate (or cluster) forming the unit of the crystal. This preferred mode requires a certain dynamic symmetry, and stable crystals are formed by the building up of a structure providing this symmetry. (2) The general role of composition in polymorphism. A theoretical discussion of the temperature-composition diagram with particular reference to solid solution.

E. R. Dunn : Notes on North American Leptodeira (Colubrine snakes of moderate to small dimensions).

Achille Bassi : New invariants of a manifold.

G. A. Miller : (1) Enumeration of the Abelian groups whose orders do not exceed a given number. (2) Groups whose prime powers generate a cyclic subgroup.

John von Neumann : Regular rings.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, March 15

Royal Geographical Society, at 5.—Prof. C. Daryll Forde: "A Study of Settlement in the Cross River Area, Southern Nigeria".

Tuesday, March 16

Eugenics Society, at 5.15—(at the Linnean Society, Burlington House, W.1).—Miss H. Holland, Dr. J. R. Baker and Dr. S. Zuckerman: "Birth Control: The Last Year's Work".*

Wednesday, March 17

Chemical Society, at 5.30—(at the Royal Institution, Albemarle Street, W.1).—Prof. V. M. Goldschmidt: "Principles of Distribution of Chemical Elements in Minerals and Rocks" (Seventh Hugo Muller Lecture).

University College, London, at 5.30.—Dr. V. Friedenreich: "Blood Groups and Genetics".*

Royal Meteorological Society, at 7.30.—Prof. D. Brunt: "Clouds, Natural and Artificial" (Symons Memorial Lecture).

Royal Society of Arts, at 8.—H. D. Henderson: "Problems of the Displacement of Labour by Mechanization".

Thursday, March 18

Chemical Society, at 4—(at Grosvenor House, Park Lane, W.1).—Annual General Meeting and Anniversary Dinner (at 7).

Royal Asiatic Society, at 4.30.—Dr. Li Chi: "The Culture of the Shang Dynasty".

British Institute of Radiology, at 8.—Prof. S. Russ and Miss G. M. Scott: "Some Biological Effects of Continuous Gamma Irradiation. With Notes on Protection".

Friday, March 19

Geographical Discussion at 4.30—(at the Royal Astronomical Society).—Discussion on "Instrumental Seismology" to be opened by J. J. Shaw.

Royal Institution, at 9.—Lord Rutherford, F.R.S.: "The Transmutation of Heavy Elements".

Institute of Physics, March 18–20.—Second Conference on Industrial Physics to be held at the University of Birmingham. Subject: "Optical Devices in Research and Industry".

March 18, at 4.30.—Prof. A. Fowler, F.R.S.: "Spectroscopy in Industry" (Presidential Address).

Appointments Vacant

Applications are invited for the following appointments, on or before the date mentioned:

Scientific Officer (air armament—ref. 308/*C*) and Assistant (grade II Experimental and design work—ref. 309/*C*) in the Directorate of Scientific Research, Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough (March 19).

Junior Scientific Officers and Assistants (grade III) in the Building Research Station, Garston and the Road Research Laboratory, Harmondsworth—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (March 19).

Assistants (grade III) for library work in the Department of Scientific and Industrial Research—The Establishment Officer, D.S.I.R., 16 Old Queen Street, Westminster, S W.1 (March 19).

Examiner in the Non-Metallic Section, A.I D. Test House, Kidbrooke—The Secretary (S.2 d,), Air Ministry, Kingsway, F.C.2 (March 20).

Tutor and Lecturer in Biology in the Maria Grey Training College, Salusbury Road, London, N.W.6—The Secretary to the Principal (March 20).

Chief Technical Instructor in the Government Trade School, Haifa—The Secretary (*SIR/CA*), Board of Education, Whitehall, S.W.1 (March 21).

Sub-Assistant Botanist in the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (March 22).

Three Scientific Officers in the Explosives Directorate, Research Department, Woolwich, S E.18—The Chief Superintendent (March 27).

Assistant (grade II—engineering) in the Admiralty Technical Pool—The Secretary of the Admiralty (C.E Branch) (March 27).

Research Palæontologist in the University of Western Australia—The Agent General for Western Australia, Savoy House, 115/116 Strand, W.C.2 (March 31).

Technical Assistant in the Information Department and Library of the British Non-Ferrous Metals Research Association—The Secretary, B.N F M.R.A , Regnart Buildings, Euston Street, N.W.1 (March 31)

Senior Lecturer in Social Anthropology in the University of the Witwatersrand—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W C 2 (March 31).

Lecturer in Pure and Applied Mathematics in the Battersea Polytechnic, London, S.W.11—The Clerk to the Governing Body (April 17).

Lecturer in Geography and Demonstrator in Physiology in Bedford College for Women, Regent's Park, N.W.1—The Secretary (April 20)

Professor of Anatomy in Middlesex Hospital Medical School—The Academic Registrar, University of London, W C.1 (April 23)

Assistant Director of Pathology (with title of Nuffield Reader in Pathology) in the University of Oxford—The Secretary of Faculties, University Registry, Oxford (April 26).

Senior Lecturer in Physiology in the University of Liverpool—The Registrar (May 1).

Professor of Chemistry in the University of Western Australia—The Agent General for Western Australia, Savoy House, 115/116 Strand, W.C.2 (May 17).

Promotion of International Peace

THE attention which has been given in Great Britain during the past few months to considerations of defence and the Government's programme of rearmament, despite all the scepticism expressed as to any effective defence against attack from the air, has rather over-shadowed the other side of defence against war—the removal of its causes. To this positive aspect of the question the International Peace Campaign has the great merit of directing attention, and the appeal for support of the British National Committee of the Campaign, which has recently been issued over the signature of Viscount Cecil, has claims on the interest of every scientific worker.

The need for a more balanced handling of the problem of peace and national defence is unquestioned by well-qualified observers. The International Peace Campaign, as Viscount Cecil points out, has come into existence for the sole purpose of arresting the drift towards war, and aims at strengthening and co-ordinating organizations which already exist and are interested in peace, and although its organization takes no part in party politics, it is all the more important that it should secure support from all sections of political opinion if its policy and development are to be free from bias, however unconscious or unintentional.

The four objectives of the campaign naturally include the reduction and limitation of armaments by international agreement and the suppression of profit from the manufacture and trade in arms. This objective is not, however, over-stressed, and its practical impossibility at the time need not deter the most convinced supporter of the Government programme from supporting the Campaign, while at the same time it serves as a reminder of the necessity of such action when international tension is lessened and a positive defence policy bears fruit.

The first objective of the Campaign, however, the recognition of the sanctity of treaty obligations, should command universal assent. However inapplicable the provisions of the Versailles treaty may be under the conditions of to-day, and however overdue their supercession, the method of unilateral repudiation adopted by Germany has dealt heavy blows at the assumption of international good faith and the respect for treaties upon which all international order and co-operation are finally based. It is not merely that Germany's other treaty obligations are viewed by other countries with the same cynicism and distrust as have been Italy's since her Abyssinian expedition—a cynicism which no announcements of Mediterranean agreements or understandings can dispel—but also confidence has been undermined, and mutual distrust, itself the chief enemy of peace, has been greatly multiplied.

It is on this main point that Dr. L. P. Jacks insisted in a recent thoughtful criticism of the League Covenant contributed to the *Hibbert Journal* under the title "Alexander Hamilton and the Reform of the League". Covenants between sovereign States can depend only on the good faith of the contracting parties, and if that is insecure nothing can be made safe. Coercive measures intended to circumvent bad faith are exposed to the bad faith they would circumvent, and indeed are more vulnerable to it, since they tend to emphasize any bad faith which exists, inflame it and afford fresh opportunities of mischief. Accordingly, Dr. Jacks urges that the elimination from the Covenant of the last traces of the coercive element and the fatal assumption upon which it rests would have an immense and salutary psychological effect.

This argument that the better atmosphere thus created would permit the League of Nations to achieve far more effectively its proper function of protecting human welfare by international co-operation on positive lines finds strong support in a careful study of public opinion as a safeguard to peace delivered by Prof. E. H. Carr as the inaugural lecture of the Wilson chair of international politics at University College, Aberystwyth, on October 14. Reviewing the various divergent sections of opinion, from the pacifist and the isolationist to the collectivist, which to-day are found supporting the cause of peace, Prof. Carr emphasizes the necessity of regarding international politics not as a pure but as an applied science, in accordance with Aristotle's assertion that "the end of the study of politics is not knowledge but practice". Accordingly, he does not regard a system of collective security involving automatic military obligations as likely to gain sufficient support in Great Britain to be practical. He believes, on the contrary, that in this country public opinion is not prepared to support war as an instrument of any kind of policy, whether in defence of collective security or not.

Prof. Carr maintains that support of the Covenant in Great Britain is, in fact, subject to the over-riding consideration that it involves no risk of bringing the country into war, and that public opinion will not be prepared for many years to apply the Sanctions article against a Great Power. Although he does not discuss the amendment of the Covenant, as a matter of practical politics, support of Dr. Jacks' suggestion might be read as a corollary of his remarks.

There will accordingly be perhaps less unqualified support for the third objective of the International Peace Council—the strengthening of the League of Nations for the prevention and stopping of war by the organization of collective security and mutual assistance. Though Prof. Carr's belief in the possibility of isolating war will not be shared by many, and though he asserts his disbelief that the time is ripe for the establishment of anything like an international police force, there is still plenty of ground in common with the supporter of collective security. Public opinion undoubtedly presents a far more determined obstacle to war-mongering in any form than it did a generation ago. The area of the world's surface over which war has become unthinkable has been immensely extended, and with wise handling might even yet be much greater, despite the great tragedies of missed opportunities which have marked the last two decades The increased power of Governments to-day of influencing public opinion, whether by broadcasting or through the Press, should warn us against overrating the restraining effect of public opinion in any time of crisis except in so far as it is really informed and independent. Moreover, the whole trend of events in Spain and in Abyssinia strengthens the case for organizing effectively collective force behind law if civilization is to be preserved.

The most urgent problem if peace is to be preserved and democracy survive is in fact that of peaceful change, which forms the fourth objective of the Campaign and upon which Prof. Carr lays the greatest stress. The establishment within the framework of the League of effective machinery for remedying international conditions which might lead to war is the most urgent task of our generation, and offers an immense field for impartial scientific investigation. There can be no rule of law unless there is working machinery for making and re-making law, and no sanctity of treaties without effective means for altering or re-making treaties which are no longer applicable to the prevailing conditions.

Nothing in fact is so imperative at the present time as the need for demonstrating that such questions as raw materials, population, colonial territories and the like can be dealt with justly and impartially by a process of peaceful change and not merely at the demand of *force majeure.* The greatest function of public opinion, whether expressed through the International Peace Campaign, or in any other way, is to insist on the Government exploring the possibilities in this way to the utmost so as to remove and not engender further friction. Nor should it be forgotten that peace is dynamic and not static, and, just as much as war, involves risks and ventures. Only as the nations and the Governments are prepared to run those risks and to make those ventures can we hope to develop a civilization and a social and international order in which in days of peace the human mind and spirit can find expression no less nobler than they have done in the past in days of national extremity or calamity in war. A creative peace is in fact a first essential if science, no less than art and religion, is to retain its full freedom of expression and bring yet richer treasures to the service and inspiration of mankind.

A Compendium of Bengal

Life and Experiences of a Bengali Chemist
By Prafulla Chandra Rây. Vol. 2. Pp. viii + 469. (Calcutta: Chuckervertty, Chatterjee and Co., Ltd.; London: Kegan Paul and Co., Ltd., 1935.) 6*s*.

THE second volume of Sir P. C. Rây's "Life and Experiences" is concerned chiefly with economics and politics and very little with chemistry. The author calls it "a compendium of India under British rule"; but this description is rather too comprehensive. The book is written by a Bengali who loves Bengal and has devoted his life to its welfare. To him, the rest of India is an incident, sometimes even an encumbrance. Other patriotic Indians hold similar views regarding their particular province or State, and the reader may thus readily realize some of the difficulties which confront the Central Government and the reasons for the establishment of provincial autonomy.

A quarter of the book is devoted to an illuminating history of education. There is little doubt that education in India has gone seriously astray. The uneducated masses have no real desire for their children to be educated, and thus we meet the phenomenon of the school which hurriedly comes into existence on the arrival of the inspector, to vanish as rapidly when he has departed. In such circumstances, progress can scarcely be rapid. But what is progress ? Experts hold fundamentally divergent opinions as to what constitutes a suitable form of education, and, even if there could be some general agreement as to the system, how is the education of some three hundred million people to be paid for when they are too poor to contribute even fourpence a head per year (the amount of the much-debated salt tax)? It would seem that the only solution of the problem is for patriotic Indians in every village to devote an hour or so daily to the instruction of their weaker brethren.

It is generally assumed that universal primary education is a desirable goal, but is this so ? If any conclusions can be drawn from the thousands of luckless graduates who, after many years of self-denial and overwork, are unable to secure the salary of a cook or a chauffeur, even primary education may not always be a blessing.

A recitation of the misdeeds of the Government of India fills most of the remainder of the volume. No one will deny that blunders have been committed, the greatest of which, perhaps, was when, with seven dead Delhis before them, Government set to work to construct an eighth, and this not merely a temporary winter residence for officials but a city which was to surpass in magnificence and costliness any of its predecessors. Small wonder if critics assume that Government has no desire for economy and no real interest in the welfare of the country, and, indeed, that behind every action, no matter how well-meaning, there lurks some sinister intention.

A man of science, however, who knows how readily his carefully planned experiments may go astray, before leading to improvement and final progress, should be chary of finding fault with others until he can point out a better way. Granted that Government has made mistakes, is it not going rather far to accuse it of spreading malaria by building a railway embankment many years before the cause of the disease was known, or to speak of their "criminal and wilful neglect of irrigation" when they have initiated schemes which are the admiration of the world ? The peace which India has so long enjoyed is said to have emasculated the people, and communalism to have been deliberately fostered. Statements such as this, in which the book abounds, can do nothing but detract from its value. Nor does it help greatly to compare modern India with the more prosperous India of the past. Infant welfare, improved sanitation, inoculation against disease, albeit but a fraction of what might be done, and the reduction of famine mortality by the opening up of communications, have all resulted in the presence of three million extra mouths to feed every year. As the struggle for existence grows keener, individual strives against individual, community against community and province against province. Is this the fault of Government, or some inherent defect in the character of man ?

Japan and Italy are held up as examples of what may be accomplished, but there is a fundamental difference. The Japanese are bound together by a patriotism greater, perhaps, than that of any other nation, while the progress made in Italy is the result of a compulsion which would never find favour in India, even if it were administratively possible. The Indian, on the other hand, is essentially an individualist, although there have been many broad-minded and great men who have the country's interest at heart. Sir P. C. Rây is fully aware of this trait; indeed, he says: "A great drawback in our national character is that, as soon as the founder of the concern dies, his sons or successors quarrel among themselves as to who should manage it". He points out frankly many other shortcomings of his people and exhorts them to frugality, honesty of purpose, self-reliance and patriotism. Those who know him are well aware there could be no better preacher, for, throughout his long life, he has practised every precept he preaches with a vigour which is beyond admiration—yet how many heed his advice ? True reform must come from within; until the individual learns that service to others is as vital as self-interest, no Government on earth can bring prosperity in place of poverty and misery. H. E. W.

Shabti Figures

Shabtis

Illustrated by the Egyptian Collection in University College, London: with Catalogue of Figures from many other Sources. By Sir Flinders Petrie. (British School of Archaeology in Egypt and Egyptian Research Account, Forty-first Year, 1935.) Pp. x+16+45 plates. (London: British School of Egyptian Archaeology, and Bernard Quaritch, Ltd., 1935.) 25*s*.

IN this volume, which forms part of the series of monographs planned by the author to cover the development of the principal departments in the civilization of ancient Egypt, Sir Flinders Petrie has surveyed from its origins the history of the custom of placing one or more small representations of the mummy in the tomb. The survey is more complete than any previous study that has been attempted, and covers not only the collection at University College, London, numbering 650 examples, but also a further 565 from the Italian and other museums. In addition to the register or catalogue of these, there is a corpus of the inscriptions, and the types are illustrated in a series of excellent photographs.

In an analysis of the material which precedes the catalogue, Sir Flinders first examines the evidence bearing on the origin of the custom. Although the ushabti figure, properly speaking, does not appear until the Twelfth Dynasty, he traces the conception from which it grew back to the pre-dynastic custom of separating the skull from the disarticulated bones and burying it either in an unnatural relation to them, or above the pile of stones which covered them. Evidently burial had been delayed in order to secure the help of the ancestral spirit, possibly by keeping the skull in the house. Analogous customs of West Africa are quoted in support. By the Twelfth Dynasty the idea of the terrestrial habitation for the soul, involving the provision of house, furniture and other appurtenances of a life on earth, had given place to a translation to the realm of Osiris, where not only were pleasures to be enjoyed, but also duties had to be performed. When once the conception had gained currency that such duties were the function of the ushabti figure, it was only a step, though it was not a step taken until the end of the Eighteenth and beginning of the Nineteenth Dynasties, to the idea that the ushabti was not a representation of the deceased, but a slave. Then the one figure, hitherto single, except in Royal burials, took on added numbers, until it was necessary to include overseers with whips. In the later dynasties there were frequently so many as four hundred or just under. The duties the shabti figures were to perform were by no means light: originally the weaving of cloth, to this was added the carrying of sand and later the cultivation of the soil. Sir Flinders, by his study of the date at which variations in the inscriptions on the shabti appear, is able to trace the development at various periods in the conception which inspired their use.

The material from which the shabti figures were made varies from stone to wood, and even mud was used. The most familiar form is perhaps that made of pottery and covered with blue or green glaze. The form varies in like manner, and at times becomes almost shapeless.

In connexion with the use of wood for a figure with magical properties, Sir Flinders refers to the Greek parody of the idea in Lucian in the story in which a magician turns a piece of wood or a household article into a servant to perform any function for which he requires it, and then transforms it back again, the jest being that the teller of the story, knowing part of the formula, sets an animated piece of wood to carry water, but being unable to make it stop, cuts it in two and doubles the danger of inundation. Sir Flinders tells us that the story has been revived in a modern French symphonic poem; but there are many other versions. It was a familiar story in the Middle Ages and is told of a pupil of the thirteenth-century magician, Michael Scott, who tried to emulate his master. It is interesting to note that the duty of carrying sand associated with the dead in the realm of Osiris, also appears in connexion with Michael Scott, who set the Devil to carry sand on the shores of Fife.

Aromatic Diazo-Compounds in Industry

The Aromatic Diazo-Compounds and their Technical Applications
By K. H. Saunders. Pp. xii+224. (London: Edward Arnold and Co., 1936.) 12*s*. 6*d*. net.

IN this very concise treatise the author has summarized the history of the industrially important diazo-compounds since their earliest recognition by Peter Gries in 1858 until the present time. The various methods of preparing diazonium salts are reviewed, including the recent outstanding discovery made independently by Hodgson and Schoutissen that *o*-diamines can be made to give the reactions of bisdiazonium compounds.

The rapid development of industrial activity in the ice colours based on Naphthol *AS* and its analogues has led to many devices for stabilizing diazo-compounds. Among these the use of the stable forms of diazo-sulphonates is noteworthy as leading to valuable monoazo-dyes of the variamine blue class. The author presents a clear and comprehensive account of the abstruse researches on the constitution of diazo-compounds carried on for a number of years by Hantzsch, Bamberger and many others, and more recently by Angeli.

At present the industrial utilization of diazo-compounds is much in advance of our theoretical knowledge concerning their constitution. It is pointed out that the score or more of aromatic amines supplied commercially in a high degree of purity for ice-colour work could now furnish for research purposes diazo-derivatives which were not available formerly. In addition to the couplings which lead to industrially important hydroxyazo- and aminoazo-dyes, the diazo-compounds serve for many synthetic operations in aromatic chemistry, whereby the halogens, including fluorine, and several other non-metals and some metals are introduced into benzenoid nuclei. All these reactions are described and there is a full bibliography which includes references to the literature of heterocyclic diazo-compounds.

In spite of the intricacy of the subject matter, the text is remarkably free from errors and there are adequate author and subject indexes, although the former does not always tally with the references at the end of each section. This book may be recommended with confidence as the most up-to-date monograph on the diazo-reaction in the English language. G. T. M.

Racial Portraiture: a Sculptor's View

A Sculptor's Odyssey
By Malvina Hoffman. Pp. xxii+416+128 plates. (London and New York: Charles Scribner's Sons, Ltd., 1936.) 24*s*. net.

SIX years ago, the Field Museum of Chicago formulated a bold and novel project. Dissatisfied with the conventional lay-out of the anthropological section of the average ethnographical museum, it conceived the plan of a sculptural Hall of Man, to consist of one hundred sculptured heads and figures, modelled from life, and embracing the main surviving anthropological types—a far-sighted break with museum tradition, which, if judged solely on the statistical evidence of subsequent visitors, has amply justified the trustees' vision. To Miss Malvina Hoffman, who already at that time filled a unique and outstanding position in the world of sculpture, was entrusted this colossal task; and this volume—well named her Odyssey—leads up, through her early years of struggle, to the inner story of its achievement.

As an unassuming record of travel and observation, of perseverance in the face of unexpected difficulties, of the transport of the hundred precious clay figures in China and Japan, Java and the South Seas, Burma, India, and Europe, it is a fascinating piece of writing, though marred at times—particularly towards the close—by an odd sentimentality: but for the technical reader it has a wider and two-fold significance. Here was a comprehensive anthropological problem, which might have been approached *ex cathedra*, from the academic angle, each sculptured figure being created an elaborate synthesis of exact facial angles and accurate anatomical measurements. In practice, mercifully, the task was planned and executed by an artist: and, as Sir Arthur Keith writes of Miss Hoffman's work, "we professional anthropologists can never hope to obtain by mere measurements the accuracy of racial portraiture which comes by instinct to the true artist". In London, there is small opportunity to study Miss Hoffman's sculpture, though some idea is given by the two heroic figures above the entrance to Bush House: but the large success of her Hall of Man can readily be estimated from the magnificent plates in this volume.

A further significance of the book is implicit and to some extent explicit in Miss Hoffman's narrative. Hers is not an art in which the hand of the master is withdrawn immediately the original clay is modelled, leaving all subsequent work to plaster caster, *metteur au point*, or bronze founder. It is abundantly evident from her writing that Miss Hoffman has served an apprenticeship to her craft comparable to that served by the medieval and Renaissance craftsman: and while, obviously, the casting of a heroic bronze is essentially a piece of fine team-work, she has herself mastered in practice every detail—building the armature, modelling, plaster casting, and all the subtleties and scientific tricks of casting in bronze by the sand and lost-wax techniques. The book is an opportune reminder of the ancient gospel once more being preached to young artists and craftsmen—clear recognition of the limits imposed upon execution by the material properties of the medium: and complete mastery and understanding of technique, in contradistinction to mere empirical facility.

Not the least interesting section of the book is that which gives in compact form the succession of exact manipulations which lies between the clay model and the patinated bronze. Nevertheless, the book is essentially one for the non-specialist, for whom a friendly narrative of travel is woven through pages of magnificent photographs.

P. D. R.

Survey of British Agriculture

Regional Types of British Agriculture
By Fifteen Authors. Edited by J. P. Maxton. Pp. 318. (London: George Allen and Unwin, Ltd., 1936.) 12*s*. 6*d*. net.

ALTHOUGH Great Britain is a small country, it presents a surprising diversity of soils, a wide range of altitude and rainfall, and extreme variations in density of population. These factors have resulted in a large number of farming systems which only have one thing in common, namely, a very close suitability to the environment in which they have grown up. A good general knowledge of the type of agriculture carried on in the more important natural divisions of the country should be part of the equipment of all students and teachers of agriculture, and for the increasing numbers of those who, while not actually in the farming industry, are interested in its development in relation to national policy.

The description of farming systems has certainly not been an overworked field in the past. There are the classical county surveys done for the Board of Agriculture at the end of the eighteenth century, and numerous articles describing farming districts in the volumes of the *Journal of the Royal Agricultural Society*. We have also descriptions of farming tours made in recent years, of which those of Rider Haggard (1901–2), and Sir Daniel Hall (1910–12) are perhaps the best known. But much has happened since then, and types of agriculture that held their own for generations have yielded before the pressure of present-day economic movements, while others have entered into relative prosperity as a result of Government action.

The units of the present volume are the fifteen advisory provinces into which Great Britain is divided, and the agriculture of each is described in almost all cases by the head of the department of agricultural economics. Naturally the province is far too large an area to be treated as an agricultural whole, so that a system of farming zones within provinces has been adopted, and the characterization of the separate regions has been set out. Since some eighty separate regions are treated, it will be understood that descriptions are necessarily brief, and the authors have in many cases been compelled to hold very close to the matter in hand, avoiding the entertaining detours and personal touches that writers who have had more elbow-room have been able to allow themselves.

The treatment of each province is on uniform lines. After a general discussion of the physical and geological features of the area and a note on the distribution of population, the regions are set out and described in more detail. There are numerous references to the modification in classical systems of husbandry designed to meet changing economic conditions. Clear maps are provided showing altitude, chief features, towns and the boundaries of the separate agricultural zones.

The book makes a useful addition to the rather scanty and scattered information on regional agriculture in its present-day aspects. H. V. G.

Magnetochemie

Von Prof. Dr. W. Klemm. (Physik und Chemie und ihre Anwendungen in Einzeldarstellungen, Band 1.) Pp. xv+262. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1936.) 18 gold marks.

By magnetochemistry is meant the examination of the problems of chemical structure in the light of magnetic measurements and modern magnetic theory, and it is clear that the author of this book has thoroughly studied the more important methods of susceptibility determinations and the theoretical significance of the results. He does not assume that his readers already know all about the matters on which he writes, and his work is a fine example of careful exposition based upon a proper attention to fundamental conceptions and definitions. The outline of experimental methods and technique is by no means exhaustive, but it should be adequate for the average chemist who is likely to read the book.

The author gives a very full discussion of the earlier theories of para- and diamagnetism, although he follows other writers in obtaining an expression for the molar susceptibility of a diamagnetic substance in which a 6 appears, without giving a complete explanation of how the 6 gets there. The survey of the newer quantum theory of magnetic moments is particularly good, and the explanation of the temperature-independent type of paramagnetism, predicted by Van Vleck, is very neatly set forth. The influence of temperature and chemical combination upon magnetic susceptibilities is also fully discussed.

A large portion of the book is naturally devoted to problems of chemical structure, and the treatment of the magnetic properties of inorganic compounds and metals is especially helpful, for it includes data which the reviewer has not found elsewhere. It can be cordially recommended to all who are interested in the magnetic aspects of chemical problems.

L. F. B.

Le plateau de Meghalaya (Garo-Khasi-Jaintia):

étude géographique d'une région naturelle de l'Inde. Par Dr. Shiba Prasad Chatterjee. Pp. 170. (Paris: Les Presses modernes; London: The Bibliophile, 1936.) 10*s.* 6*d.* net.

"Meghalaya" is the name given by Dr. Chatterjee to that isolated block of peninsular India which sticks out westwards like a promontory from the Naga Hills into the plain of Assam-Bengal. The meaning is 'abode of cloud', on the analogy of Himalaya, 'abode of snow'. Although the "Khasi and Jaintia Hills", as the name appears on maps, are connected by a high ridge with the Naga Hills, they form no part of them, being very much older.

Dr. Chatterjee, who is a geologist, is the right person to have written this little study, and he has done it very thoroughly. He clearly distinguishes between the Shillong Plateau in the centre, the Garo Hills in the west, leading down to the plains, and the Jaintia Hills in the east. The physiographical distinction, well shown in the contoured sketch map, is convincing, based partly on structural and partly on climatic differences; but to call them natural regions is to exaggerate their importance. The distinction is mainly one of relief.

The author gives a clear account, illustrated by line drawings and by sections, of the structure and evolution of the region, followed by a chapter on the climate. Cherrapunji has attained world-wide fame for its 600 inches of rainfall—not every year! The attempt to divide the flora of Meghalaya into three sub-floras, corresponding with the three physiographical areas, is not so successful; and the vegetation map naturally suffers from compression. The drawings by Mr. Frank Simpson are pleasant, and give a good idea of this interesting country of which we have heard little since Hooker's "Himalayan Journals".

(1) Heat Engines

By S. H. Moorfield and H. H. Winstanley. Second edition. Pp. vii+326. (London: Edward Arnold and Co., 1935.) 6*s.* 6*d.*

(2) Examples in Heat and Heat Engines

By T. Peel. Second edition. Pp. vi+146. (Cambridge: At the University Press, 1935.) 5*s.*

(1) For those beginning the serious study of the theory, Messrs. Moorfield and Winstanley's primer "Heat Engines" has already obtained recognition as a suitable medium of introduction to the subject. The second edition follows the lines of the first, but is enlarged by the addition of a chapter on steam turbines. It thus covers the work usually required for the Ordinary National Certificate and presents a difficult subject in an easy and convincing way very suitable for those of limited attainment in mathematics.

(2) "Examples in Heat and Heat Engines", by T. Peel, also in its second edition, contains fifty sets of graduated and arranged questions taken from *A* and *B* papers of the Cambridge Engineering Tripos or prepared in accordance with that standard—a very useful series for those preparing for the advanced examinations.

Lorenz Oken und Georg Büchner:

Zwei Gestalten aus der Übergangszeit von Naturphilosophie zu Naturwissenschaft. Von Jean Strohl. (Schriften der Corona, Band 14.) Pp. 106. (Zürich: Verlag der Corona; Münich und Berlin: R. Oldenbourg, 1936.) 5 gold marks.

Few people to-day have ever heard of Georg Büchner, while their ideas about Oken turn mainly on his "Lehrbuch der Naturphilosophie", a rather fantastic work, and his controversy with Goethe as to the vertebral origin of the cranium. They lived in a period of controversy which played around irrational theories but was often somewhat poetic in its conceptions. The philosophers of the early part of the last century were indeed imaginative and honest, but too abstract to provide a popular theory of life. The author of the little book before us, however, does not set out to expose this, but to produce a pleasant and readable book on two interesting personalities—and he has succeeded.

A New Alloy of High Density

By Dr. C. J. Smithells

THE use of large masses of radium in beam therapy necessitates the provision of adequate protection. At the same time, the actual container should be as small as possible if the radium is to be used efficiently, particularly in inaccessible positions. Absorption of the harmful γ-radiation by metals is directly proportional to their density, and for this reason a smaller container, or bomb, can be used if it is made of a metal of high density. The bomb and nose-piece, to give the necessary protection, weigh 50–100 lb. and have usually been made of lead, which has a density of 11·35 gm./c.c. The actual nose-piece has sometimes been made of gold, but this metal is too expensive to be used for the bomb itself.

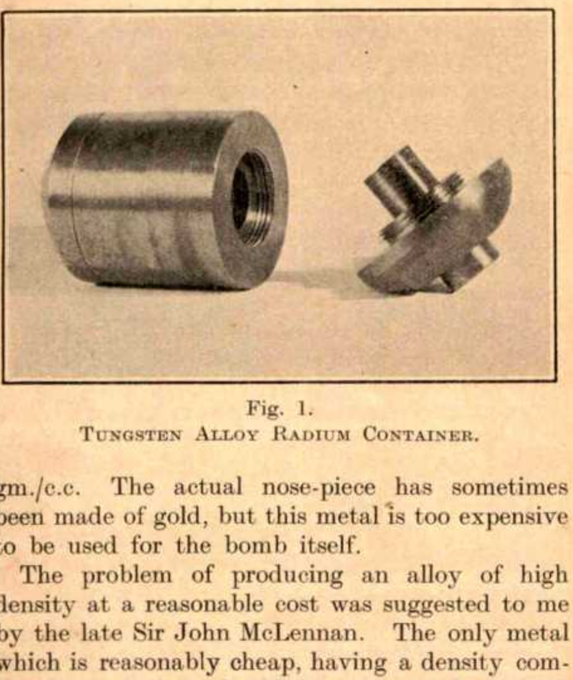

Fig. 1.
TUNGSTEN ALLOY RADIUM CONTAINER.

The problem of producing an alloy of high density at a reasonable cost was suggested to me by the late Sir John McLennan. The only metal which is reasonably cheap, having a density comparable with that of gold, is tungsten; but a high density is only attained when the metal has been sintered at about 3000° C., and no means are available for heating masses approaching 1 cwt. to such a high temperature.

The problem has been solved at the Research Laboratories of the General Electric Co. at Wembley by mixing tungsten powder with a small proportion of a metal of lower melting point, so that a liquid phase is formed on heating to a moderate temperature. If the tungsten particles are wetted by the liquid metal, shrinkage results, and densities closely approaching the theoretical are obtained. Either nickel or copper are suitable additions for this purpose. Copper melts at 1084° C., whilst nickel and tungsten form a eutectic melting at just above 1400° C. If the heating is carried out in an atmosphere of hydrogen, the tungsten particles are wetted in both cases. 5–10 per cent of either nickel or copper powders, or a mixture of the two, is added to the tungsten powder, which is then pressed to the required shape in a steel die and heated in hydrogen at 1450° C. for an hour. Since a linear shrinkage of about twenty per cent occurs during sintering, allowance must be made for this in designing the dies.

The alloy generally used for radium bombs contains 5 per cent copper and 5 per cent nickel, and the density of the finished pieces lies between 16·3 and 16·5 gm./c.c. With a smaller proportion of added metal it is possible to obtain densities in excess of 17. The density of the new alloys is therefore fifty per cent greater than that of lead, and a corresponding reduction in the size of the bomb is possible.

The microstructure shows particles of tungsten embedded in a matrix of copper, copper-nickel, or nickel-tungsten according to the composition employed. Although tungsten itself is practically not machinable, the alloys can be readily machined with ordinary tools, drilling, tapping and screw-cutting presenting no difficulties. Where large surfaces have to be machined, it is an advantage to use a tool of the cemented tungsten carbide type.

Owing to the difficulty of pressing very thick sections, it has been found most economical to construct radium bombs by welding together a number of annular rings. These may be up to one inch thick and five inches in diameter. Their surfaces are accurately machined and then placed on one another with 0·1 mm. nickel foil between them. On heating to 1450° C. in hydrogen, the nickel melts and forms a perfect weld. A complete bomb is shown in Fig. 1. About ten bombs have now been made in this way and are in use in various hospitals in Great Britain. One or two installations employing them have already been referred to in NATURE[1].

Although developed primarily for radium work, tungsten alloys made on this principle are finding several industrial applications. An alloy of this type has been used successfully for balancing crankshafts for internal combustion engines used in racing motor-cars. It seems likely to find a similar application in aircraft engines. It has also been used in gyroscopes and for similar purposes where high density combined with strength is necessary. The tensile strength of the sintered alloys is about twenty-two tons per square inch, but although they can be hot worked, they have very little ductility cold.

The largest application, however, is as a contact material for heavy-current circuit breakers. For this purpose, the alloy is applied as a facing brazed on to the copper contact arms. Contacts having a superficial area of about two square inches have been used successfully to break currents of 130,000 amperes at 6,000 volts. Tungsten has, of course, long been recognized as a useful contact material, owing to its low vapour pressure, but the pure metal could not be produced economically in the large sections required for high-power electrical engineering purposes.

---

[1] NATURE, 139, 52 (1937).

The Starling in the United States of America

By Dr. Walter E. Collinge

THE dangers arising from the introduction of foreign species of animals have frequently been dwelt upon by zoologists of all nationalities. The results of such acclimatizations have nowhere been more pertinently summarized than by Palmer[1] in 1893.

The species to which we here wish to direct attention is the European starling (*Sturnus vulgaris* Linn). Thirty-five years ago we possessed a very meagre knowledge of the feeding habits and economic status of this bird, and it was introduced into various countries in the belief that it was distinctly beneficial to the farmer and fruit-grower.

The earliest record I can find of its introduction into the United States is that made by the Acclimatization Society of Cincinnati, Ohio, which liberated a number in the winter of 1872–73. In 1877 the American Acclimatization Society liberated a number in Central Park, New York, and again in 1890 about sixty birds were released. In 1889 and 1892 thirty-five pairs are reported to have been released at Portland, Oregon. In April 1890 eighty birds were released in Central Park, New York, and forty more in March of the following year. Later, smaller numbers were liberated in different localities.

From these various importations the starling has increased and spread throughout the whole of the north-eastern States, and it is gradually spreading westwards. The extension of the range and the methods of spread have been fully dealt with by Mrs. Mary Thacker Cooke[2], while a fully detailed account of the food and feeding habits has been published by Kalmbach and Gabrielson[3]. To this latter I shall refer later.

Few seem to have regarded the starling as a potential danger to the United States. Writing in 1916, Forbush[4] stated, "Already the starling has begun to show a capacity for harmfulness which may be expected to become more prominent as its numbers increase. . . . Perhaps it is too early yet to say what will be the final result of the introduction of the starling into this country. Its value as an insect destroyer is plain; but its unchecked increase may prove a calamity to several species of useful native birds, and from the experience of other countries we may assume that it is likely to become a pest to the fruit grower."

In any attempt to arrive at the true economic position of this bird, we must not lose sight of the fact that it is a powerful animal with a strong and formidable weapon of defence in the shape of its beak. Moreover, it exhibits great powers of caution and intelligence.

A further point of interest is its great fecundity; it is exceedingly difficult to estimate even approximately the actual number of pairs of breeding birds in the United States; but for the purpose of illustrating the rate of increase, we will presume that in 1933 there were 200,000 pairs, and that each pair reared three pairs of young, half of each sex, and that all lived together with their offspring. The progeny and parents in a single year would total 1,600,000. At the end of 1934 this number would have increased to 6,400,000, the addition in 1935 would make the total 25,600,000, while at the end of 1936 there would be more than 102,000,000 birds.

These figures are calculated on the basis of a single brood per year, though in many parts of the country there are two broods. Even allowing for a very high rate of mortality, it is clear that the annual increase is enormous. Herein lies a potential danger which should not be overlooked.

Knowing how injurious this bird has become in Great Britain and also in Australia, New Zealand

and Tasmania, let us consider the nature of its food in the United States. An examination by Kalmbach and Gabrielson of 2,157 stomachs shows that 57 per cent of the food consists of animal matter and 43 per cent vegetable matter, and of this animal content 41·55 per cent is composed of insects. The full details are as follows: weevils 8·50 per cent, ground beetles 5·71 per cent, May beetles 2·24 per cent, other beetles 3·14 per cent, grasshoppers 12·41 per cent, caterpillars 6·04 per cent, millipedes 11·71 per cent, Hymenoptera, Hemiptera, Diptera and other miscellaneous insects 5·93 per cent, animal garbage 1·32 per cent, cultivated cherries 2·66 per cent, other cultivated fruits 1·75 per cent, wild fruits 23·86 per cent, grain 1·16 per cent, vegetable garbage 13·57 per cent.

In Great Britain, we obtain rather different figures: animal food constitutes 51 per cent and vegetable food 49 per cent. Of the former, 26·5 per cent consists of injurious insects, 2·5 per cent of beneficial insects and 3·5 per cent of neutral insects, 8·5 per cent of earthworms, 6·5 per cent of slugs and snails, 1·5 per cent of millipedes, and 2 per cent of miscellaneous animal matter. Of the vegetable food, 20·5 per cent consists of cereals, 2·5 per cent of cultivated roots and leaves, 15·5 per cent of cultivated fruits, 7 per cent of wild fruits and seeds of weeds, and 3·5 per cent of miscellaneous vegetable matter. Summarizing these figures, we find that 36·5 per cent of the starling's food constitutes a benefit to the agriculturist, 41 per cent an injury, and 22·5 per cent is of a neutral nature.

A brief comparison of the figures resulting from the above two investigations shows that in Great Britain the starling has taken to feeding upon cereals and cultivated fruits to a much greater extent than in the United States, and we have little doubt that as this bird increases in numbers a similar change in its feeding habits will take place in America.

There was a time, no doubt, when in Great Britain this bird was a most useful and beneficial one to the agriculturist, just as it is at the present time in Ontario[5], but once let it reach the high-water mark of abundance, and it becomes equally injurious. It is this fact which we wish to stress, for once this bird reaches the high-water mark it will prove a much more serious pest than the European house-sparrow.

By the enactment of wise repressive measures this calamitous state of things may be averted; but if the situation is not properly realized and things are allowed to drift, then the agriculturists and fruit-growers of the United States will suffer as seriously as, or even more than, those of Great Britain.

Writing in 1912, I stated[6]: During the first six months of the year the food in an urban district was distinctly of an insectivorous character, and the evidence from the food generally would lead us to place the species amongst those birds beneficial to the agriculturist and horticulturist, but a similar record extending over the same period taken in an agricultural district would, in all probability, reveal the starling as a destroyer of newly sown grain, and extended over the summer months, would show that it inflicts considerable losses upon fruit growers. As the result of further investigations, I was forced to the conclusion that "the starling has become a plague in the land and a source of great national loss".

It is a pity that this undesirable alien was ever introduced into the United States, but that is past history; what must be looked to at the present is to see that a very careful watch is kept upon this bird from all aspects, and that its numbers be strictly limited. For the information of how this may best be done American citizens may look with every confidence to their famous and unrivalled Department of Economic Ornithology in the Biological Survey.

A New Method in Biogeography

THE last two or three decades have witnessed great progress in the studies of ecological and geological factors of distribution of plants and animals, but the results of these studies have had little influence on biogeographers, whose work is still mainly concerned in the parcelling out of the globe's surface into regions, provinces, etc., characterized by statistical ratios of endemic forms and those common to several divisions. The methods of biogeographical work remain generally the same as in the time of Wallace, and a great proportion of literature (zoogeographical in particular) is devoted to discussions of the exact boundaries between formal divisions. When, however, two types of fauna or flora, different in their geological origin and adjusted to different ecological conditions, have to develop in close geographical proximity, there can be no linear boundary between them. Their various elements will penetrate more or less deeply into the main area occupied by the other type, this process being usually favoured in the case of one of the types by slow climatic changes in a certain direction. When such changes, for example, favour the spread of forests over a steppe area, some 'islands' of steppe with their characteristic plant and animal population will still remain as evidence of former conditions. Usually, in calculating statistical ratios, such inclusions of alien fauna, or flora, are not distinguished from the elements of the dominating population, which is obviously incorrect.

The need for more careful analysis of populations of geographical areas is better realized by botanists than by zoologists, and modern plant geographers (Braun-Blanquet, Eig, and others) base their analyses on 'phytogeographical elements', and discriminate between continuous distribution of a species, its penetration into a strange area and its 'insular' occurrence in the latter. Zoogeographers, on the other hand, are generally satisfied with the old methods of characterizing the fauna of a country by the full quota of its species regardless to the type of their occurrence, and by drawing line boundaries where, at the best, a more or less broad transitional zone exists in Nature.

Partial attempts to improve on these antiquated methods are not lacking in biogeographical literature, but no definite proposals of a new way of representing distributional facts have been made until the recent paper by Dr. B. K. Stegmann "On the Principles of Zoogeographical Division of the Palæarctis as the Basis of a Study of Types of its Ornithofauna" (*Bulletin Acad. Sci. U.S.S.R.*, pp. 523–563 + 7 maps; 1936). Dr. Stegmann condemns the idea of mapping zoogeographical divisions separated by line boundaries, and bases his work on the 'types of fauna' which are characterized by the common ecology and past history of their members. The distribution of each type of fauna is to be shown on a map in a special colour, whether it is continuous, or disrupted and 'insular'. Unfortunately, no coloured map is given in the paper (which is only a preliminary one), but a series of black and white maps, each showing the distribution of one type of fauna, is most instructive. Two of these maps are reproduced here (Figs. 1 and 2) in the hope that this will make clear the principle, which is of course very simple.

In the Palæarctis the author distinguishes seven types of bird fauna, as follows:

(1) *Arctic type*, which has a circumpolar distribution, being connected ecologically with the arctic zone north of the tree limit. Some arctic elements occur discontinuously in the alpine zones of European and Asiatic mountains, so far south as the Pyrenees, the Alps, the Urals, Tarbagatai, Altai, Khankhai and Kentei mountains. They are absent from the Caucasus and Tian-Shan.

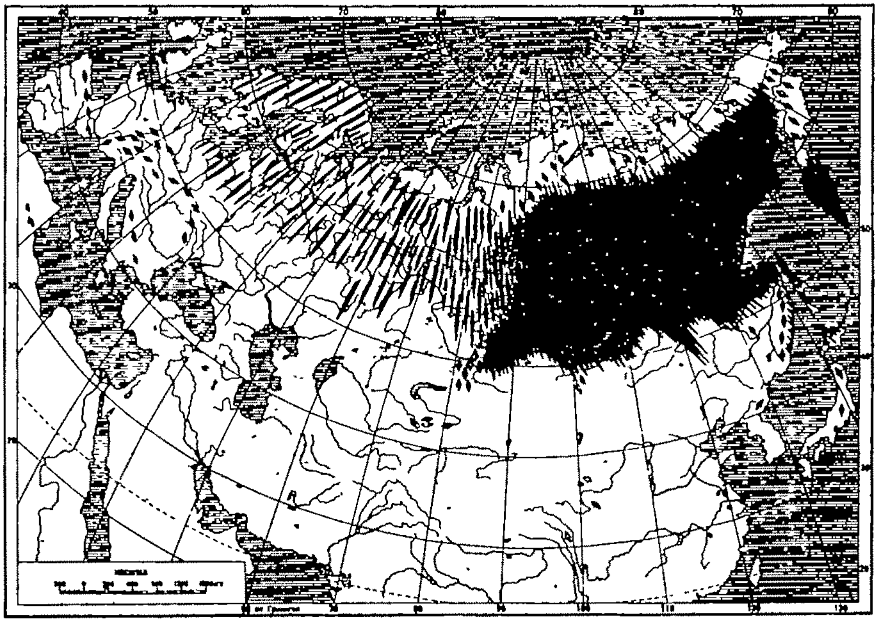

Fig. 1.

DISTRIBUTION OF THE SIBERIAN TYPE OF FAUNA.

(2) *Siberian type*, or the fauna of taiga (boreal coniferous forests). This populates a continuous area in Eastern Siberia and extends, with gradual reduction in the number of species, to the south Siberian mountains, and those of northern Mongolia, as well as through the northern half of western Siberia into Scandinavia. Some typical taiga birds occur sporadically also in the forests of Central European mountains, in the Pyrenees, in Tian-Shan and even in the mountains of Kansu, Szechwan and Khawin, south-eastern Tibet (see Fig. 1).

(3) *European type*, connected with the western European deciduous forests, and extending continuously, but in a gradually narrowing zone, to the southern Urals. Many species belonging to this type penetrate into northern Europe and south-western Siberia, while some occur sporadically in southern Siberia and even trans-Baikalia The forests of North Africa are also populated by birds of European type, and the same applies to forests of the Caucasus and Turkestan (see Fig. 2).

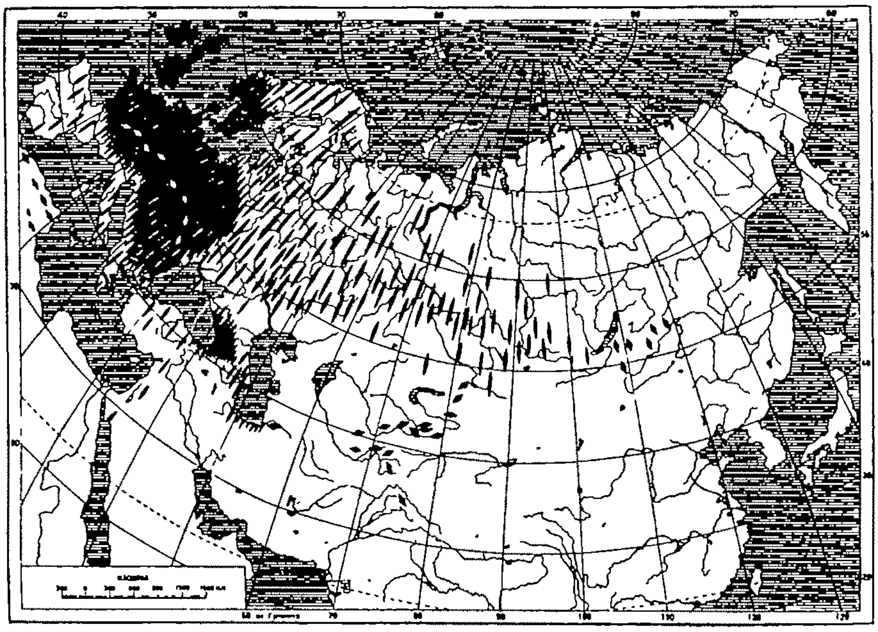

Fig. 2.
DISTRIBUTION OF THE EUROPEAN TYPE OF FAUNA.

(4) *Mediterranean type*, comprising species connected with xerophilous scrub, steppes and deserts. This fauna populates southern Europe, North Africa and south-western Asia up to Iran and Afghanistan. Only a few Mediterranean elements penetrate farther east to the Mongolian Altai and Alashan. Northwards, these elements extend to southern England, Germany, the Hungarian plain and the south Russian steppes.

(5) *Mongolian type*, consisting of species living in the steppes and cold deserts of Mongolia, whence many of them extend into Turkestan. A few Mongolian species occur so far west as Iran, Syria, Asia Minor, Egypt and even northern Africa (two species). In the north they occur in isolated steppe 'islands' in the midst of the Siberian taiga.

(6) *Tibetan type*, found in the alpine zone of Tibet and the Himalayas and, sporadically, on all high mountains of Palæarctis and even of North America.

(7) *Chinese type*, consisting of elements ecologically connected with broad-leaved forests of south-eastern Asia. It prevails in Japan and China, where it gradually passes into the Indo-Malayan fauna. To the west, this type of fauna extends over the Himalayan forests to Kashmir, a few elements penetrate to Afghanistan and Turkestan, and one even to the Caucasus. Northwards, many Chinese elements extend to Amurland and some even to trans-Baikalia and the Altai; isolated occurrences are recorded so far north as Yakutsk.

It will be seen, even from this very brief summary, that the result of a careful application of the new principle will be either a series of maps, each showing the distribution of one type of fauna (like the two reproduced here), or a composite map in colours showing the great complexity of population of the Palæarctis, and proving the futility of any linear boundaries, since these would inevitably cut across the actual faunistic and ecological connexions and produce a highly artificial picture. There can be no doubt, therefore, that this new method of biogeographical mapping represents a great step towards a more scientific treatment of distributional problems, as compared with the statistical biogeography of the present day. Of course, this type of investigation requires a thorough analysis of the ecology, phylogeny and past history of each taxonomic group before it can be referred to one or the other faunistic type, but this is the only way to put biogeography on a sound scientific basis.

The difficulties of such work are great and the pitfalls are many, as can be seen even in the example of the paper under review, where the Mediterranean type of fauna obviously includes at least two profoundly distinct faunas, those of the dry Mediterranean scrub and those of treeless deserts. Even in the case of birds, the differences are striking, and this is still more so for other groups of animals. However, this is only a minor fault of the paper, which should mark a new period in the development of biogeography, and deserves the serious attention of zoologists and botanists.

B. P. UVAROV.

Obituary Notices

Prof. Giuseppe Sergi

BY the death on October 17, 1936, of Giuseppe Sergi, professor emeritus of anthropology in the University of Rome, at the advanced age of ninety-five years, the science of man has lost not only its senior exponent, but also a student whose interests in that many-sided field of knowledge were both broadly distributed and profoundly rooted.

Giuseppe Sergi was born at Messina, Sicily, on March 20, 1841. He was educated at Bologna; and at the age of nineteen years, he took part in Garibaldi's expedition to Sicily. After that adventure, he devoted himself to scientific studies and in 1880 was appointed to a chair in the University of Bologna. Four years later he became a professor in the University of Rome, where he founded the Institute of Anthropology, of which he remained the head, occupying the chair of anthropology in the University until 1916, when he retired, receiving the title of professor emeritus. In retirement, however, he was far from inactive; and during the remaining twenty years of his life many publications, some of considerable importance, came from his pen. At the time of his death, he had made more than four hundred contributions to the printed literature of science, and in addition had written frequently on social and political subjects.

Sergi's early published work, of which the first recorded item appeared in 1868, was concerned with the history of certain concepts in philosophy; but it was not long before he manifested his interest in ethics and psychology. Like many of his countrymen, he had come under the influence of Herbert Spencer. Not only did he contribute an introduction to an Italian version of Spencer's system of ethics; but also he himself wrote a history of moral philosophy, and contributed to the discussion of Spencer's conception of the State as an organism. Psychology, however, proved a more lasting, or at least a more prominent, interest in his mental development, to which he returned time and again. He was one of the first to give attention to experimental methods in this science. Nor did he neglect psychic manifestations, upon which he produced a book in 1880; but here his point of view had special reference to the biological aspect, an aspect which is prominent in all his not inconsiderable work on abnormal and criminal psychology. His "Principi di Psicologia sulla Base della Scienza sperimentale", first published in 1873, appeared in several revised editions, and he was the author of a number of works on this subject of an authoritative character. He also wrote with understanding on the methods of pedagogy and discussed the merits of the Froebellian system.

During the years, formative as they may be regarded, between the late 'seventies and the early 'nineties, Sergi's attention had been turning more and more towards what was his main life-work. In 1876 he had been joint editor of the Bulletin of the Academy of Medicine at Rome, and not long after, as his publications show, he began to take a serious interest in anthropology. In 1882 he published a paper on an improved method of measuring the facial angle. It was, however, in the following year that a decisive interest determined his future bent. In the introduction to a little volume published towards the close of his life, "Alba Longa" (1934), he tells us how in 1883, when he was spending a holiday in the valley of the Po with his friend Eduardo Brizio, the archæologist, he was attracted by the problem of the ancient inhabitants of that region, and it was, he says, in three papers dealing with the Ligurians, the Celts and the necropolis of Villanova, which he wrote and published in that year, that he began the long series of studies which led up to and culminated in his determination of the physical characters and ethnic history of the Mediterranean race.

From this time onward, Sergi was busily engaged in preparation for his great work. Every skull to which he could obtain access, ancient and modern, not only from Italy and the Mediterranean, but also from every quarter of the globe, was carefully examined. The list of his papers published at this time bears eloquent testimony to his activity. Nor did he neglect collateral lines of inquiry. So far back as 1872, in a work entitled "History and Philology", a book of Indo-European studies, he had shown his interest in the derivation and history of the early peoples of Italy. He now gave renewed attention to the archæology of the Mediterranean area, as appears in a book on the method of racial history, "Antropologia e Scienzi Antropologici" (1889), which is remarkable for its insight into the nature of the problem and its breadth of view, especially when the date of its publication is taken into account.

A second product of these years of preparation was an innovation in the method of craniology, which Sergi himself undoubtedly considered his most important contribution to the method of anthropological science. Anthropological method, he maintained, should not differ from zoological method; and, therefore, he argued, more attention should be given to the morphology of the skull: the anthropologist should be able to determine race by inspection, just as the zoologist is able to determine species, whatever it may be, and whatever region it may come from. In reaction both from the extravagant comparisons of the day, in which similarities and identities were discerned in widely distributed types solely on the basis of similarities of craniological measurement, and from fallacies of interpretation, Sergi proposed to substitute for measurement the observational examination of the skull, more especially when viewed *in norma verticali*. He therefore classified skulls into groups, according to the outline, which he distinguished by various terms such as 'beloid', 'ovoid', 'pentagonoid' and the like. These revolutionary views were first put forward at the International Anthropological Congress at Moscow in 1893. Commenting some years later on the results of his researches on the Mediterranean race, Sergi said that he had followed the various peoples of the Mediterranean with their racial names in ancient and modern history, and had examined the ancient and modern skulls of the peoples of Iberia, Liguria, Central and Southern Italy, Greece, Asia Minor and Egypt, and among them all, from Spain to Hissarlik, he had found about a dozen forms of skull, and these were common to all, while the ancient cranial form invariably resembled the modern, whatever foreign influence might have intruded. Further, he maintained that these forms did not occur at all among other peoples of Europe, such as Celtic, Germanic and Finnic—a statement, be it said, which has been regarded by his critics as at least subject to qualification.

Sergi's great work, "Origine e Diffuzione della Stirpe mediterranea", which must be regarded as the crown of his labours, appeared in 1895. A German translation was published in 1897, and an English version appeared in 1901. This last contained so much additional matter as to constitute what was virtually a new work. It is of interest, and of indubitable importance in assessing Sergi's position, to bring "The Mediterranean Race" into relation with the anthropological thought of the time of its publication. Without in any way impugning Sergi's impartiality in viewing the facts, it may be said that he was inspired by a reaction against 'Germanism', the view then held in certain quarters that the early civilization of Europe, that is, the civilization of the Mediterranean, was due to the impact on the peoples of that area of a tall, long-headed, fair race, identified with the Aryans, who were held to have originated in Northern Europe, and further, were said to be represented in the modern population by the Germans and their racial affinities. In reply to this last contention, Sergi argued that the Germans were not to be distinguished from Celts and Slavs with whom they had always been associated, and with whom they were often confused; while the long-headed fair peoples of northern Europe, the Reihengraber and Viking types, were of Mediterranean origin.

Sergi, in fact, maintained that the neolithic population of Europe and the Mediterranean area, the Mediterranean race, the North African peoples, and the long-headed population of Northern Europe were three offshoots, or varieties of one original Mediterranean, or Eur-African race, which had sprung from Africa, and of which the Mediterranean was the centre of dispersal. The Mediterranean culture, which had ultimately blossomed into the civilization of Greece and Rome, was entirely a product of this Mediterranean race, developing a seed which had been brought from Asia Minor. So far was this development from being the work of the Aryan speaking peoples, that it was they, the peoples of Asiatic, and not European, origin who, he maintained, had been the destroyers of that culture. It will be remembered that at the time this was written, Sergi had before him only the evidence of the so-called Mycenean age, and the Minoan civilization of Crete, which would have added strength to his argument, was as yet almost unknown.

Any attempt to estimate the value of Sergi's work and methods in the subsequent development of anthropological studies must take into account at least two factors. Of these, one was the development at about the same time of the application of biometric methods to the study of man, which to a certain extent and with limitations rehabilitated anthropometric measurement as a means of observation; and the second was the publication of Deniker's classification of the races of Europe (1897 and 1904) and Ripley's work "The Races of Europe" (1901), which following more nearly traditional methods of study, appeared to afford greater precision in working than Sergi's scheme. Sergi himself, though continuing to employ his method of inspection and classification of form throughout his life, later abandoned his extreme attitude towards craniometry: but his arguments, though not adopted in full by his fellow anthropologists, have secured in an increasing degree that reliance should be placed on observational study of the skull to bring out differences which are obscured by or escape measurement.

Of Sergi's later work, considerable though it is in volume, little need be said here. It never attained the international importance of his Mediterranean studies. In 1908 he published the results of an application of his theories to study of the relation of the Mediterranean race to the peoples of Europe generally, and later extended his published work to cover the field of the races of man as a whole, and the question of the origin and descent of man, where he turned to consider the geological and palæontological evidence bearing on anthropological studies. In this field his most important work is "L'Uomo", which appeared in 1911. That he maintained fully his mental vigour and flexibility to the end is demonstrated in a remarkable book "La più antica Umanità vivente" (1930), in which he skilfully interpreted the evidence of Rhodesian man in tracing a line of descent from Neanderthal man to representative types in modern races. E. N. F..

Dr. A. Daniell

By the death of Dr. Alfred Daniell in Edinburgh on January 12, there passed one who had made a distinct mark in the world of science. Born at Llanelly eighty-three years ago, he early showed a bent towards educational attainment. In consequence, while still a boy, he was sent north to pursue his studies in the University of Edinburgh. He had a distinguished course in arts, medicine and science, obtaining many successes and distinctions, particularly in science. For a time he was lecturer in the Medical School. He also worked under Prof. (afterwards Lord) Lister in the old Royal Infirmary, where he had charge of the Out-patient Department. He was the author of the well-known "Text Book of the Principles of Physics" published by Messrs. Macmillan and Co. so long ago as 1884, and "Physics for

Students of Medicine". These publications were successful, especially the former, which was translated into various foreign languages.

In 1886 Dr. Daniell became an advocate of the Scottish Bar, and in 1894 he sought a wider sphere, becoming an English barrister—in each case seeking to utilize his scientific attainments in his new profession.

Dr. Daniell was faithful through life to his Alma Mater at Edinburgh, of which he became M.A., D.Sc., and LL.B. He took part in certain of its activities while health permitted. He was also a fellow of the Royal Society of Edinburgh.

The last twenty years of Dr. Daniell's long life were spent in Edinburgh. He was chiefly occupied in writing a new book called "Problems in Physics", which he was able to finish, but was not destined to see published. He also revised, and partly rewrote, his "Text Book". But for some time before his death, failing health greatly curtailed his activities.

WE regret to announce the following deaths:

The Right Hon. Sir Austen Chamberlain, K.G., P.C., Chancellor of the University of Reading since 1935, and chairman of the Court of Governors of the London School of Hygiene and Tropical Medicine and of the Governing Body of the British Postgraduate Medical School, on March 16, aged seventy-three years.

Mr. A. Gallenkamp, founder of A. Gallenkamp and Co., Ltd., makers of laboratory equipment, on February 26, aged eighty-eight years.

Prof. A. Pictet, honorary fellow of the Chemical Society and formerly professor of organic chemistry in the University of Geneva, on March 12, aged eighty years.

Dr. Elihu Thomson, the well-known American electrical engineer, who received the Hughes Medal of the Royal Society in 1916, on March 13, aged eighty-three years.

News and Views

Prof. T. C. Hodson

THE announcement of the impending retirement of Prof. T. C. Hodson from the William Wyse chair of social anthropology in the University of Cambridge in September next will be received with regret by all who are interested in the advancement of studies in that branch of the science of man, not only within the University but also at large. When Prof. Hodson was placed in charge of this subject at first in 1926 as reader in ethnology and from 1932 as occupant of the chair which he now relinquishes, he brought to the teaching of a subject which, more than almost any other in the academic curriculum, demands breadth of view and a sense of realities, a wide and varied experience. This began after he had taken his degree at Queen's College, Oxford, with some years as a member of the Indian Civil Service stationed in Assam, and embraced service with the Indian forces during the Great War, and a period as principal of an ex-Service men's college, of which the curriculum had been strongly influenced by his faith in the educative and broadening influence of the point of view of the anthropologist in the approach to educational and cultural problems. It is in some sense a mitigation of the regret which will be felt at Prof. Hodson's retirement that his successor, who has also served in India, by experience and by conviction, is well qualified to continue the work which Prof. Hodson has always had most nearly at heart, in the firm belief that a knowledge of anthropology is the best and the most essential qualification in the administration of the affairs of the varied peoples of the British Empire.

Social Anthropology at Cambridge

DR. JOHN HENRY HUTTON, of St. John's College, Cambridge, who is to succeed Prof. T. C. Hodson, was educated at Chigwell School, and Worcester College, Oxford. Dr. Hutton was appointed lecturer in the Faculty of Archæology and Ethnology at Cambridge last year, on his retirement from the Indian Civil Service. He entered the Service in 1909, serving under the Government of Assam, and being awarded the honour of C.I.E. in 1920. In addition to his administrative duties, Dr. Hutton was responsible as honorary director for the ethnographic survey of the tribes of Assam, and himself produced two volumes, one on the Angami Nagas (1921) and one on the Sema Nagas (1929) in the series of monographs on the Naga tribes published under the auspices of the Assam Government. Dr. Hutton's abilities as an anthropologist and as an organizer of survey work in anthropology and demography were recognized when he was seconded from the service of the Assam Government to take charge of the Census of India, 1931. As superintendent of the Census, he wrote an introductory study of the ethnic problem involved in the composition of the population of India, summing up and analysing the evidence which has accrued since the publication of Sir H. H. Risley's Census of 1901 and calling for modification in the views then put forward. Reference was made to Dr. Hutton's work in NATURE of September 5, 1936, p. 394. Mr. Gregory Bateson, of St. John's College, Cambridge, has been elected to the William Wyse studentship in social anthropology in the University of Cambridge for a period of three years. Mr. Bateson is the author of the recently published work "Naven" (see NATURE of March 13, p. 454) in which he gives an account of some of his observations among the Iatmul tribes in an expedition to the Sepik River, New Guinea, in 1933, and elaborates an extension of the 'functional' method in sociological investigation.

Iron and Steel Institute: Bessemer Gold Medals

THE Bessemer Gold Medals for 1937 of the Iron and Steel Institute have been awarded to Colonel N. T. Belaiew and Aloyse Meyer. Colonel Belaiew of Paris, a former pupil of Prof. Tschernoff of the Military Academy, Petrograd, has, during the last twenty-five years, published a number of papers of outstanding importance on metallurgy. These have dealt mainly with the crystallization of metals, and in particular steel. His studies of the constitution and solid geometry of pearlite, sorbite and troostite demonstrated the true width of the lamellæ in these structures and the relation between the angle of section and the apparent width. His suggestion of a definite unit of crystal size of iron has been confirmed from other sources. He also studied the primary and secondary crystallization in steel and the origin of the 'Widmanstatten' structure in steel and meteorites. His insight is strikingly shown by his insistence on 'granulation' in the austenitic zone, the explanation of which has been provided by the subsequent discovery of the delta-gamma change in iron at very high temperatures. He has studied the manufacture and uses of Damascene steel and related the results to the manufacture of high-class steels at the present time, in particular high-speed steel.

M. ALOYSE MEYER, of Luxemburg, is an honorary vice-president of the Institute, and is well known as head of the Société Anonyme ARBED, the great Luxemburg combine and the second largest iron and steel company in Europe. He has rendered unique services to the iron and steel industry as president, since 1928, of the Entente Internationale de l'Acier. In addition, his encouragement of the acquisition and diffusion of technical information and metallurgical knowledge in the Luxemburg-Lorraine district has been invaluable to the progress of the industry; he was actively connected with the introduction of the Thomas-Gilchrist process of steel manufacture into the district—the Hauts Fourneaux et Aciéries de Dudelange was one of the first works in Europe and the first in the Luxemburg-Lorraine district to adopt this method, which revolutionized the manufacture of steel on the Continent. Since the Great War, he has been responsible for the introduction of modern American blast-furnace practice in the works under his control.

Richard Anthony Proctor (1837-1888)

IN the mid-Victorian era there were no more popular books on astronomy than those of Richard Anthony Proctor, the centenary of whose birth falls on March 23. Possessing a remarkable power of lucid exposition and almost unbounded energy, in his comparatively short life he published about sixty separate works, wrote numerous memoirs and delivered many lectures in Great Britain, the United States and Australia. He was, however, no mere exponent, and in the little leisure he enjoyed he studied the planet Mars, plotted on a single chart the 324,198 stars of Argelander's "Durchmusterung" and made the important discovery of 'star-drift'. Proctor was the son of a London solicitor and was born in Cheyne Row, Chelsea. His father died in 1850 and left the family ill-provided for; so Proctor became a clerk in the London and Joint Stock Bank, but was able after a year or two to study at the University of London; at the age of nineteen years he entered St. John's College, Cambridge, graduating as 23rd Wrangler in 1860. He then read for the law, but this was soon abandoned for science, and in 1865 he published his first book, "Saturn and its System".

PROCTOR married before leaving Cambridge and for a time was in pecuniary difficulties. In 1868 he scored his first financial success with his "Half Hours with the Telescope". This was followed by his "Other Worlds than Ours". It was about the time this appeared that after working five years without a holiday he wrote, "I would willingly have turned to stone-breaking or any other form of hard and honest but unscientific labour if a modest competence in any such direction had been offered me." For a short time he taught mathematics in a school at Woolwich. He was elected a fellow of the Royal Astronomical Society in 1866; in 1872 he became honorary secretary to the Society, but this he resigned in order to undertake a lecture tour in America. The tour was a success and in 1879, after the death of his wife, he made a tour to Australia. In 1881 he founded the periodical *Knowledge*, and then returned to the United States, marrying a widow, Mrs. Crawley, and settling at St. Joseph, Missouri. A few years later he transferred his house and observatory to Florida. In September 1888 he was about to sail from New York on a visit to England but was attacked by fever and died in hospital on September 12, at the age of fifty-one years.

Printing and Allied Trades Research Laboratories

THE new Laboratories of the Printing and Allied Trades Research Association were officially opened by H.R.H. the Duke of Gloucester on March 9 in the presence of the Advisory Council of the Department of Scientific and Industrial Research and the Council and members of the Research Association. The laboratories are situated just off Fleet Street in the centre of London's printing district, and comprise about seven thousand square feet devoted to chemical and physical laboratories, library and offices for the investigation of the major and the day-to-day problems of the printing, newspaper, ink and paper industries. The basement has been converted into an optics laboratory for colour measurement in connexion with colour printing and the measurement of the opacity of paper, etc. A strong-room in the basement has been converted into a constant humidity laboratory where the temperature and relative humidity are maintained at 65° F. and 65 per cent.

All paper-testing work, on strength and printing quality, is carried out in this laboratory, where is also installed a small printing machine on which printing tests can be carried out under controlled conditions.

GENERAL offices and library are housed on the ground floor of the Laboratories. From the library, the Intelligence Section of the Association's work is operated and the "Review of Literature" published. The physics department is contained on the first floor where work on colour fading, examination of adhesives and bookbinding materials are carried out. This department also contains a section for photomicrographic work on paper fibres, inks, prints and printing alloys, and a dark room for ultra-violet and infra-red work. The upper floor has been converted into two chemical laboratories. One is mainly for analytical work in connexion with the day-to-day problems submitted by member firms, and the other set aside as a chemical research laboratory for dealing with the longer-ranged problems connected with the working properties and drying of printing inks, lithography, photogravure printing, stereotyping and electrotyping, etc. It is the aim of the Research Association to deal with both the day-to-day problems and the longer-ranged work connected with printing processes and raw materials, and to build up a scientific background to one of the 'craft' industries so that the inherent difficulties, now aggravated by increased speeds of production, can be eradicated and the future developments of the industry guided by scientific research.

The West Indian Volcanoes

AT the Friday evening discourse delivered at the Royal Institution on March 12, Sir Gerald P. Lenox-Conyngham described "Montserrat and the West Indian Volcanoes". The island of Montserrat has recently suffered from a series of earthquakes. They began about the beginning of 1934 and continued with varying intensity all through 1934 and 1935. In the autumn of 1935 the inhabitants sent a petition to the Governor praying that steps should be taken to discover, if possible, whether there was danger of an eruption. Their anxiety was due to their recollection of the events of 1902 when eruptions of the Soufrière of St. Vincent and of Mont Pelé of Martinique did terrible damage. Such an eruption in Montserrat would be most dangerous to the town of Plymouth. As a result of the petition, a small expedition consisting of a geologist and a physicist was sent out. Frequent severe shocks were felt up to November 1935. After that date the activity of the volcano became steadily less. A good measure of success was attained in locating the positions of the foci, and it is now known that they were all situated in a belt about four miles wide which crosses the island from south-west to north-east. The West Indian island arc bears strong resemblance to the East Indian arc that runs eastwards from Java. In 1929–30 Dr. Vening Meinesz of the Dutch Geodetic Commission made a gravity survey of the seas around these islands and found that there is a belt of negative gravity anomaly lying outside the island arc. The circular form of island and mountain arcs is suggestive. It is probable that the form is determined by the intersection of a thrust plane with the sphere. Mr. P. Lake has pointed out that the radius of the arc gives the dip of the fault where the thrust plane cuts the surface. It is believed that gravity determinations combined with the consideration of the curvature of the island chain and of the probable position of the over-thrusting foot of the tectonic arc on which the islands have been built up by volcanic agency will throw light on the structure of the region.

New University Studies

AT the recent annual meeting of the Court of Governors of the University of Birmingham, the vice-chancellor, Sir Charles Grant Robertson, noted a small decline in the number of students in the University, possibly due to the decline in the birth-rate (though periods of 'boom' in trade have on previous occasions been associated with a slackening in the entry to the University). The Faculty of Medicine, however, shows no such falling off. He commented with satisfaction on the success of the Appointments Board and the evidence of an increasing demand for the product of the University in industry—in fact, during the past year the demand on the Appointments Board exceeded the supply. Sir Charles dealt with the lack of the study of the social sciences in English universities. It has been suggested that the education of a university graduate is incomplete without some such study, but there is the difficulty of finding the time without omitting some other part of the curriculum. It appears probable that little can be done unless there is a specialist social science degree course, or the subject is made one for a post-graduate course of at least one year; and then there is the problem of finding posts for such graduates, with adequate pay and prospects of promotion, so long as the wide field of municipal civil service is barred to university graduates. Sir Charles expressed sympathy with the Government's desire to promote physical training in universities, but, in addition to the fact that the necessary trainers do not at present exist, the thorny problem of compulsion or non-compulsion would have to be solved.

The Universities and Social Science

A SPEECH entitled "A Citizen Challenges the Universities", delivered by Sir Ernest Simon at the summer, 1936, meeting of the Council of the Association of University Teachers in Cardiff, appeared in the *Universities Review* of November last, and a reprint of it has reached us. The challenge relates to the imminent threat to democracy involved in our tolerance of such conditions as those of South Wales and other depressed areas, and the universities' alleged neglect, in the face of that threat, to do their duty by the social sciences: their failure alike to provide adequate inducements, staff and equipment for research in those sciences and for specialized study in them, and to employ effectual measures for ensuring that students, of whatever schools, shall not graduate without an active and realistic interest in the broader problems of the world to-day. The challenge is not a new one, but its urgency grows with the growing prestige of 'corporative' States. It was an outstanding motive of the remarkable series of eight university supplements published in *Time and Tide* in 1935. To that series Sir Ernest himself contributed an article on "Where our Universities Fail".

SIR ERNEST SIMON's estimate of the responsibility of the universities in this matter is based partly on the assumption (the validity of which tends to diminish) that public opinion in Great Britain is largely determined by men and women educated at the universities, and partly on the influence the universities exert on the teaching in secondary schools through university scholarships and entrance examinations, and control over examinations in those schools. His argument finds some support in the last report of the University Grants Commissioners. But arguments must be cogent indeed to overcome the inertia of university governing bodies, especially since no provision was made for research in the social sciences when the Government of the day set up the Department of Scientific and Industrial Research. In a postscript to his paper, Sir Ernest announces that the Association for Education in Citizenship is proposing to appoint a committee on the whole problem of the universities and citizenship and invites communications from persons interested in this matter. His address is, Broom Croft, Didsbury.

Public Affairs Forums in the United States

ADULT civic education through "public affairs forums" is now being energetically pushed by the United States Federal Office of Education, the present head of which, Dr. Studebaker, played a principal part in the launching, several years ago, of the pioneer forums in Des Moines. The latest official publication on the subject, a pamphlet entitled "A Step Forward" (Superintendent of Documents, Washington, D.C. 10 cents), includes an account of ten forum demonstration centres in as many different States, managed by local educational authorities. A foreword by the Commissioner strongly emphasizes the principle of local responsibility and control, but the enterprise has been financed largely out of the Federal Emergency Relief Appropriation, and several hundred relief workers have taken part as assistant librarians, research assistants, artists, writers, accountants, typists, etc. The Secretary of the Interior, in commending the Commissioner's scheme, observes that it has brought about an essential and practical contact between "those few of our citizens who are concentrating their time and effort on the pursuit of truth in the field of social problems" and the average citizen who cannot devote much time to a specialized study of these complex questions. The success of the scheme hinges on finding competent leaders for the forums, for they have the difficult task of first presenting a topic in simple language in a way calculated to sustain interest, giving a fairly comprehensive and impartial outline of the problem and the alternative solutions, and then stimulating, leading and organizing a free discussion for forty or fifty minutes. Most of them have been obtained on leaves of absence from colleges and universities. The improvement of social intelligence for the democratic control of our material resources is, says the Commissioner, the challenge of our day.

Social Services in Great Britain

"PUBLIC SOCIAL SERVICES" (Cmd. 5310. London: H.M. Stationery Office. 4*d*.) portrays statistically what may, without much exaggeration, be called the social revolution of the twentieth century in Great Britain. It shows that in the first thirty years of the century the cost of the social services referred to increased just thirteen-fold, namely, from thirty-six millions to four hundred and sixty-eight millions sterling. The first decade was marked by a rise in expenditure under Education Acts from 20 to 34 millions and the coming of old age pensions which cost 7 millions in 1910. The next decade saw a leap in education expenditure from 34 to 90 millions and in old age pensions from 7 to 21, the introduction of unemployment insurance (11 millions), national health insurance (30 millions), the mental deficiency acts, and, of course, war pensions. Between 1920 and 1930 the expenditure under unemployment insurance increased to 102 millions and under old age pensions to 37½ millions, and the widows', orphans' and old age contributory pensions acts came into force, involving, in 1930, an expenditure of 34¼ millions. During this period, expenditure under the housing acts increased from 4½ to 40 millions.

Natural History Exhibition at Wye

THE Wye College Branch of the University of London Animal Welfare Society (ULAWS) held a Natural History Exhibition at the South-Eastern Agricultural College, Wye, on March 11-13. The greater part of the Exhibition was given up to natural history specimens exemplifying the classification of the animal kingdom. Several dissections caused much interest. A fine collection of beaks and feet of birds made by a member of the Branch was on view. Specimens of bacteria, minerals and other microscopic objects were shown. In addition, there were films of animal life, including the ULAWS film on the care of dogs, which proved to be very popular. At the entrance to the Exhibition were exhibits dealing with the oil menace and the rabbit problem. The former showed how the discharged waste oil from ships and tankers floats on the surface of the sea and covers the feathers of sea-birds. Very little is enough to kill birds, causing them to die of pneumonia due to the water being able to get at the skin. A live guillemot from which the oil had been removed was shown. In all cases so far, however, the solvent used to remove this has also removed the natural grease from the feathers, with the result that the bird gets sodden when placed in water. Further experiments are being carried out by Mr. R. S. Pitcher. A gin trap for catching rabbits was demonstrated and its unsatisfactory character explained. Instead of decreasing the animals, it often leads to an increase, as has been shown in Carmarthenshire and by experiment in Devon and Pembrokeshire. Various humane traps and snares were shown together with apparatus for cyanide fumigation, but the latter was put forward as by far the best method for the painless and effective control of the rabbit. A bookstall was provided by the Cathedral Bookstall, Canterbury, and departments of the College provided many of the specimens and the apparatus. Messrs. Flatters and Garnett, Ltd., W. Watson and Co., E. Gerrard and Co., Ltd., Thomas Murby and Co. provided material, and the Folkestone Museum lent some cases and specimens.

Physics in 1936

THE rapid advances now being made in our knowledge of the physical properties of matter have made it desirable that progress reports should be published at frequent intervals; three such reports have been issued by the Physical Society, and a number have appeared from time to time in the issues of the *Physikalische Zeitschrift*, the latest being on nuclear physics by Profs. S. Flügge and A. Krebs, which occupies twenty-four pages of the issue of January 1. The Physics Forum in the issue of the *Review of Scientific Instruments* of January occupies twelve pages devoted entirely to a review of some of the most noteworthy advances, by Prof. T. H. Osgood of the University of Toledo, Ohio. It deals with the collisions of slow and fast neutrons with atomic nuclei and the knowledge of the effective cross-sections of nuclei which has been derived from them; with the scattering of one type of nuclear particle by another and the applicability of gravitational and electrical inverse square laws of action of one particle on another; the changes of mass when atoms are built up of their constituent parts; the recent removal of doubts as to the validity of the momentum explanation of the Compton effect; the frequent transformations from matter to radiation and back again which take place in the path of a cosmic ray, which make complete investigation difficult; the discovery that the oscillations of the atoms in a crystal lattice are not isotropic and the question whether supraconductivity in metals, which is suppressed instantly by a magnetic field and more slowly by a rise of temperature, is due to a surface or a volume effect. Prof. Osgood also touches on the increased accuracy of newspaper articles on scientific subjects and on "the growing recognition of the importance of physics and the training which physics gives in industrial fields". His report will be much appreciated by readers who have not the time to devote to more detailed accounts.

Electricity Costs and Factors

IN a paper read to the Institution of Electrical Engineers on March 11, Mr. J. A. Sumner pointed out some of the modern factors which affect electricity costs and charges. He makes a brief comparison between rural and urban distribution and concludes that rural areas quickly become remunerative. He suggests that the expansion of demand must be preceded by a reduction of charges for domestic supply. and a halt should be called in the downward trend of charges for power. The alteration in charges must be accompanied by a greater unification of charges and tariffs, and this can only be achieved quickly by means of a single executive authority which would have the exclusive right to direct and initiate the unification of tariffs and charges. Prices for domestic supply are generally too high to permit an extensive use of electricity, and statistics show that reductions in price tend to follow an increased demand instead of preceding it. So far as the domestic consumer is concerned, for large modern undertakings the original Hopkinson definition, namely, that the fixed charge per quarter should be proportional to the greatest rate at which a consumer may ever use electricity, is no longer applicable. If we are to retain the two part system of charging for electricity, we must reconsider the basis to be adopted for charging. The correct kilowatt charge for each consumer depends upon the time of demand, the 'diversity' of the consumers' load and of the group of consumers with whom he is associated, the voltage of supply and many other factors. It looks as if it were a problem which would not admit in practice of even an approximate solution applicable to all cases.

Cotton Growing Research

AT a meeting of the Administrative Council of the Empire Cotton Growing Corporation held in Manchester on January 26, the director mentioned the extremely bad cotton season that had been experienced in Nyasaland. He said that information received by the Corporation indicated that the loss of crop has been caused to a large extent by insect pest damage, and if this is to be reduced effectively a close season for cotton of at least two months is a necessity. The Government is anxious to extend cotton growing on the Lilongwe Plateau. The Corporation's staff has pointed out, however, that the Plateau is at about the limit of altitude at which successful cotton-growing in Nyasaland is possible; it seems, therefore, that it would be wise to try cotton there on a small scale only, before any attempt is made at extensive production. A pest survey would also be needed as a preliminary in the adjacent area. The Director referred to the importance to the natives of Nyasaland of an economic crop as a means of restricting the present uncontrolled emigration of adult males into other countries in search of work, which is the cause of the breaking up of village life and much consequent poverty and distress.

THE report of the executive stated that over a large part of Africa insect pest damage is probably the limiting factor in cotton production. One insect, the jassid, has now been to a large extent controlled by the breeding of a resistant type of cotton by the Corporation's staff at the Experiment Station at Barberton in South Africa. This variety is now grown in many parts of Africa, including Rhodesia and Nyasaland, and in parts of Tanganyika and Uganda. The Corporation's staff have therefore been turning much of their attention to work on bollworms and stainers, and it is suggested that some increase in staff is necessary. The Director decided, however, that before he would feel justified in recommending the executive committee to sanction this, he needs to be assured that the work already being done is on the right lines, and that the methods by which the different problems are being attacked are those best calculated to lead to the possibility of devising some means of control of these pests. The executive committee accordingly invited Prof. J. W. Munro, professor of entomology at the Imperial College of Science and Technology, to make a tour of the experiment stations in South Africa, Rhodesia and Nyasaland, where the work is going on, and to advise the Corporation whether this work should be continued on the present lines or modified, and to report whether the prospects of success justify extension of the work, or its maintenance on the present, or on a reduced, scale.

British Bird Sanctuaries

THE biannual report of the Watchers' Committee of the Royal Society for the Protection of Birds, issued privately, covers the 1935 and 1936 seasons at the Society's bird sanctuaries in thirteen English counties, three Welsh counties and four Scottish counties, and contains the scheme and appeal for the purchase of Dengemarsh, a stretch of shingle on the south coast of Kent that, with the adjoining sanctuaries of Walkers Outland and the Open Pits shingle, will form a continuous 1,281 acres sanctuary for terns, waders and winter visitors. The Durham (Teesmouth) sanctuary has also a scheme for the extension of watching throughout the year to protect winter visitors. The most extensive reports are made by the watchers in Lakeland, Kent, Orkney and Shetland. All the Scottish sanctuaries report 1936 as being far better than 1935. The Orkney sanctuary at Stenaday reports hen-harriers, which include an albino strain, shelduck and eiders are increasing and merlins and short-eared owls decreasing there: red-necked phalaropes are holding their own where nesting on north Ronaldshay and have a new nesting ground at Papa Westray. In the Shetland sanctuaries gannets, eider, terns, great skuas, arctic skuas, fulmars, starlings, puffins, guillemots, mallard and shags have increased but kittiwakes, razorbills (in parts) and the common gull (which no longer nests on Hermaness) have decreased. Disease has wiped out the house-sparrows from Mid Yell. Very detailed returns are made by the Dungeness and Dengemarsh watchers of Kent, this sanctuary in addition to its ternary being very rich in migrants which last year included the black redstart. Stone-curlews and red-legged partridge have also nested successfully there, but oil and oiled birds are still frequent shore troubles.

The R.H.S. Lily Year-Book

THE Royal Horticultural Society's Lily Year-Book for 1936 (London, from the Society's Office, Vincent Square, Westminster, S.W.1, 5*s*. paper, 6*s*. cloth, 1936) includes a number of contributions to a scientific understanding of lily culture. Dr. Fred Stoker has made a study of the contractile roots of these plants. He shows that members of the *Eulirion* section of the genus *Lilium* possess such structures. Much interesting information as to how contractile roots of daughter bulbils penetrate the root-plate of the mother bulb, is imparted, and the microscopic anatomy has been investigated. An attractive feature of the volume is a bibliography of more than 550 references to published works upon lilies. This has been compiled by the Abbé Souillet, and although it appears comprehensive, it does not claim to have included a large number of articles which have appeared in English periodicals from time to time. A paper by Dr. M. A. H. Tincker shows that a suitable soil temperature of 65°–70° F. is an important factor in the propagation of lilies from bulb scales. It is interesting to note that soil heating by electric cables or hot-water pipes is suggested as an aid to this method of propagation. Many other papers communicate knowledge upon geographical or horticultural aspects of lily growing, and an interesting note by Mr. P. Rosenheim announces the discovery of an early treatise on the lily, contained in a German encyclopaedia by Kruenitz and Floerke, dated 1800.

Soviet Medical Films

ACCORDING to the Soviet Union Year Book Press service, moving pictures are being used in the U.S.S.R. for the treatment of nervous and mental diseases. Prof. Sukharebsky, of the Yakovenko Psychiatric Hospital in Moscow, has obtained remarkable success by showing epileptic patients films depicting calm lakes, picturesque landscapes, etc. He has also obtained good results by the use of a film in which he hypnotizes alcoholic addicts. A plan for a series of 102 short medical films has recently been approved by the Film Committee appointed by the Commissar of Health. The series includes brain operations and diseases of the spinal cord and brain. Other films are designed to assist surgeons to carry out rapid field operations in time of war. A film entitled "A Sick and a Healthy Heart" will be made under the direction of the heart specialist Prof. Zelenin, and another will deal with the development of the child between the ages of one month and two years. The last of the series will be a film entitled "Twenty Years of Soviet Medicine".

Early Man in Japan

EVIDENCE of the presence of palæolithic man is reported from an island in southern Japan. The discovery, it is stated by Science Service (Washington, D.C.), was made by Prof. Shigeyasu Tokunaga, geologist of Waseda University, who while exploring the Island of Itoe in the Loochoo group, found numerous fossil bones of deer, which bore marks of having been worked by human hands. The deer from which the bones were derived has long been extinct, having died out in the neolithic age. Numerous teeth, antlers and bones of the same species of deer of the same age, which Prof. Tokunaga dates at anything from 30,000 to 70,000 years ago, were found in a cave. If the bones in question have in fact been worked by man, this is the first evidence of palæolithic man to be found in Japan.

Acute Poliomyelitis

The Ministry of Health has issued a memorandum upon acute poliomyelitis, an infectious disease commonly known under the name of infantile paralysis, though it may occur in adults (Memo. 166/Med. London: H.M. Stationery Office. *2d.* net). The epidemiology, clinical characters and after-effects of the disease are described and discussed, and the special diagnostic features are considered, together with a description of the changes in the cerebro-spinal fluid which serve to differentiate acute poliomyelitis from the normal and from other nervous diseases with which it may be confused.

Ray Society

At the annual meeting of the Ray Society on March 12, Prof. F. E. Weiss was elected treasurer in succession to Sir David Prain. Sir David Prain and Mr. A. W. Sheppard were elected vice-presidents, and Mr. Chas. Oldham, Mr. H. R. Darlington and Prof. F. Balfour-Browne were elected new members of Council. The Council's report stated that a translation of Linnæus's "Critica botanica" by the late Sir Arthur Hort, with an introduction by Sir Arthur Hill, would form part of the issue for 1937, which would be completed later by Mr. P. Ullyott's "British Freshwater Planarians". Others works in preparation are "British Tunicata" by Dr. John Berrill and "British Freshwater Beetles" by Prof. F. Balfour-Browne. Inquiries regarding membership of the Society should be addressed to the secretary, Dr. W. T. Calman, c/o British Museum (Natural History), Cromwell Road, London, S.W.7.

Royal Academy of Sciences, Turin

The *Atti* of the Royal Academy of Sciences of Turin (72, Part 1, 1937) announces the opening of the one hundred and fifty-fourth year of the Academy's existence. It contains the address of the president, Prof. Vittorio Cian, relating the progress of the Academy during the year 1936. As in the case of other learned societies in Italy, new statutory regulations, approved by the Fascist Government, have come into operation. This publication also includes papers submitted to the Academy in the branches of mathematical, physical and natural sciences. It is intimated that the twenty-ninth Bressa Prize will be awarded during 1937 to a scientific worker of any nationality who shall have, in the opinion of the Academy, made during the period 1933–36 "the most noteworthy and useful discovery or produced the most celebrated work in the physical and experimental sciences, natural history, pure and applied mathematics, chemistry, physiology and pathology, not excluding geology, history, geography and statistics". The prize is valued at 9,000 lire, and candidates who wish to have their work considered by the Academy are invited to submit printed copies to the Secretary (3 Via Maria Vittoria, Turin) not later than March 31, 1937.

Comets

A telegram from the U.A.I. Bureau, Copenhagen, announces the discovery of a new comet, 1937 *d* (Kozawa), on March 9 in R.A. $11^{h}\ 17\cdot3^{m}$, N. Decl. 6° 19′, magnitude 10. The object is diffuse with central condensation, and a tail less than 1° in length. The telegram has the remark "Unconfirmed", and further details are awaited. The Rev. Dr. M. Davidson, using observations on February 4 at Harvard, February 15 at Lick, and February 26 by Steavenson at Norwood, finds that Comet 1937 *b* (Whipple) is moving in an elliptical orbit, the period being about 250 years. More recent observations have been sent in by Hay and Kellaway, and Dr. Davidson is recomputing the elements with the longer time-intervals to determine the exact period. The date of perihelion passage was previously given as January, owing to an error in the telegram; it should have been June.

Announcements

The Right Hon W. G. A. Ormsby-Gore, Secretary of State for the Colonies, and Sir Henry Tizard, rector of the Imperial College of Science and Technology, have been elected to the Board of Trustees of the British Museum, in succession to Mr. H. A. L. Fisher and Sir David Prain, who have resigned.

Prof. S. A. Waksman, professor of soil microbiology in the Rutgers University, New Brunswick, U.S.A., has been elected *correspondant* of the Section of Rural Economy of the Paris Academy of Sciences, in succession to the late Sir Arnold Theiler.

At the annual general meeting of the Institution of Petroleum Technologists held on March 9, the Redwood Medal was presented to Mr. Harry Ricardo, in recognition of his contributions to the advancement of the science and technology of petroleum. Colonel S. J. M. Auld, chief technologist of the Vacuum Oil Co., Ltd., was inducted as president of the Institution at the same meeting in succession to Sir John Cadman.

At the annual general meeting of the Microchemical Club, held on March 13, the following officers were elected: *Hon. Treasurer*, Dr. L. H. N. Cooper; *Hon. Secretary*, J. R. O'Brien; *Hon. Librarian*, Miss I. Hadfield; *Members of the Committee:* Prof. H. V. A. Briscoe, Dr. J. Matthew and Dr. S. J. Folley.

The British Drug Houses, Ltd., have issued a guide in eleven pages to the Addendum (1936) to the British Pharmacopœia 1932. This guide, which should be very useful to those who have not made a detailed study of the Addendum, will be sent free of cost to members of the medical profession.

Erratum.—The name of the new secretary of the International Commission of Zoological Nomenclature (see Nature, March 13, p. 442) is Mr. Francis Hemming.

Isotope Effect in Hydrogen and Hydroxyl Bonds

THE substitution of deuterium for hydrogen has a characteristic effect on the bond lengths in hydrogen compounds, depending on the type of linkage involved. The effect has been described for ionic and covalent linkages[1]. In the case of structures involving intermolecular hydrogen bonds, no theoretical prediction of the effect could be made, because the nature of the hydrogen bond is not fully understood.

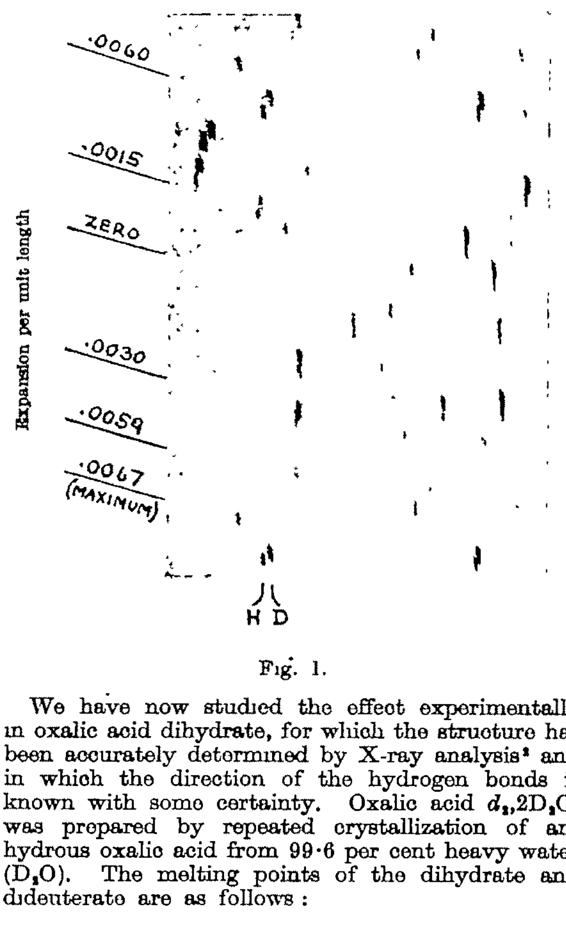

Fig. 1.

We have now studied the effect experimentally in oxalic acid dihydrate, for which the structure has been accurately determined by X-ray analysis[2] and in which the direction of the hydrogen bonds is known with some certainty. Oxalic acid d_2,$2D_2O$, was prepared by repeated crystallization of anhydrous oxalic acid from 99·6 per cent heavy water (D_2O). The melting points of the dihydrate and dideuterate are as follows:

ACID	M.P.
$(COOH)_2\,2H_2O$	99·8–100·7° C.
$(COOD)_2\,2D_2O$	95·9– 97·5° C.

This difference in melting points is in the same direction and is of the same order of magnitude as for succinic acid[3] and for other carboxylic *d* acids.

In oxalic acid d_2 $2D_2O$, there is a small *expansion* of the spacings of certain crystal planes, as compared with oxalic acid $2H_2O$, and this expansion reaches a maximum near the direction of the hydrogen bond. The effect is shown in Fig. 1, which is part of a moving film exposure taken with a Weissenberg type of spectrometer.

In this experiment a needle-shaped crystal of oxalic acid d_2 $2D_2O$, elongated along the *b* axis, was selected for comparison with a similar but slightly smaller crystal of oxalic acid $2H_2O$. The specimens were mounted in succession on the spindle of the spectrometer, with a small relative displacement in angular setting, and the reflections from the (*hol*) zones recorded on the same moving film, with copper *K* radiation. The reflections occur in overlapping pairs (cf. Fig. 1) the upper and darker component being due to oxalic acid d_2 $2D_2O$. The glancing angle of the reflection θ, and hence the spacing of the plane concerned, is given by the horizontal co-ordinate in the photograph, whilst the angular position of the reflecting plane in the crystal is given by the vertical co-ordinate. Sinθ varies from about 0·60 on the right to 0·97 on the left, and in this region, where the dispersion is large, the displacement of the oxalic d_2 $2D_2O$ lines is very marked. The expansions calculated from the displacements are shown at the side. On the extreme left the reflections split, showing the $K\alpha_1$, $K\alpha_2$ doublet.

The expansion of the oxalic acid d_2 $2D_2O$ lattice reaches a maximum near the top and bottom of the photograph, an interval which corresponds to a crystal rotation of about 180°, and in the middle it is practically zero. The directional nature of this expansion in relation to the structure is shown in Fig. 2.

Along the direction of the deuterium bonds, shown by the heavy dotted lines, the expansion is about 0·0063 per unit length. This corresponds to an expansion of the bond by about 0·016 A., or, if all the expansion occurs in the bond and not elsewhere in the structure, by about 0·044 A.

It should be emphasized that with the present technique the amount of the expansion can be measured much more accurately than the absolute value of the length of the bond itself, which is about 2·52 ± 0·02 A. This applies also to the axial ratios of the crystal. The monoclinic unit cell of oxalic acid $2H_2O$ has the dimensions

$$a = 6\cdot120 \pm 0\cdot020 \quad b = 3\cdot600 \pm 0\cdot010$$
$$c = 12\cdot030 \pm 0\cdot030 \quad \beta = 106\cdot2°$$

The comparative values for the cell of oxalic acid d_2 $2D_2O$, which roughly account for the observed expansion, are:

$$a = 6\cdot149, \quad c = 12\cdot074, \quad \beta = 106\cdot65°$$

So far, accurate observations have only been made in the (*hol*) zone, but any change in the *b* axis is probably small.

The isotope effect on the lattice parameter of lithium hydride[4] and on the alloy of palladium with hydrogen[5] is a contraction when deuterium is substituted for hydrogen, in agreement with the lower zero point energy. The converse effect of an expansion when deuterium is substituted for hydrogen in oxalic acid is apparently due to the resonance between *two* molecular structures[6] required for this type of linkage. When the isotope effect on each structure separately is considered, the energy and probably the dimensional difference between alternative deuterium structures will usually be bigger than in the case of hydrogen. Resonance will be less complete in consequence, and a larger distance between the associated groups will result when these are linked by deuterium atoms.

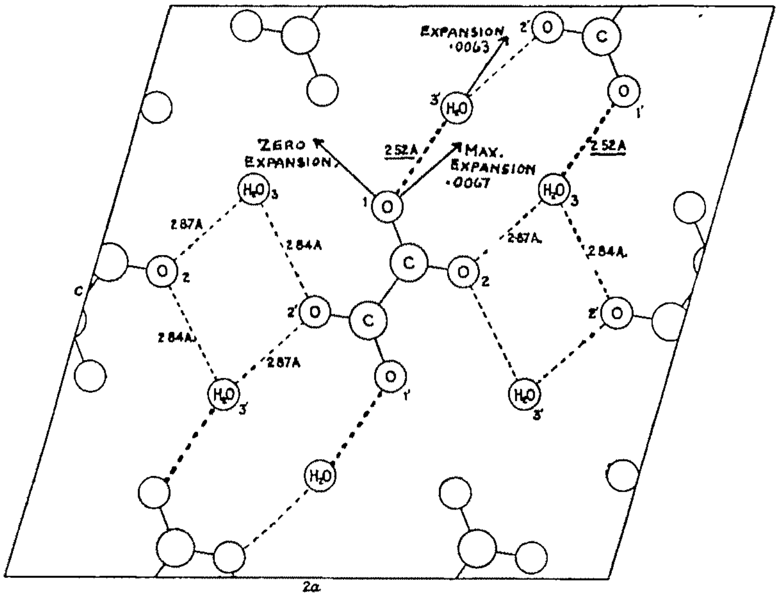

Fig. 2.

Preliminary results for other compounds under investigation show that the isotope effect depends upon the type of linkage involved. Thus, for the hydroxyl bond in α-resorcinol, the resultant effect is very small, which is in agreement with the observations of Megaw on deuterium oxide[7]. In addition to throwing light on the mechanism of the hydrogen bond, the results promise to be of considerable value in locating certain types of hydrogen linkage in complex structures.

Relations in β-Ray Transformations and the Neutrino Theory

IT is now generally agreed that the theory of the β-transformations of atomic nuclei developed by Fermi[1] on the hypothesis that a neutrino is emitted as well as a β-particle gives a formal explanation of the main phenomena. Fermi introduced an interaction of a new type between the heavy particles in the nucleus and the electron and neutrino. His theory was later modified by Konopinski and Uhlenbeck[2], in order to avoid certain discrepancies with experiment. Both the original Fermi theory and the Konopinski-Uhlenbeck form give a relation between the period of the transforming nucleus and the maximum energy of the emitted β-ray, and predict the shape of the β-ray spectrum.

Recent work[3] on the β-spectrum of radium D makes it possible to apply a stringent test to any formula connecting the period and maximum energy in β-decay. The three nuclei, thorium C″, thorium B and radium D, all give rise to permitted β-transitions and have periods in the ratios $1 : 2{\cdot}05 \times 10^2 : 3{\cdot}6 \times 10^6$. Taking the end-points of the β-ray spectra as 1790, 362 and 15 kV. respectively, the Fermi formula gives for the ratios of the periods $1 : 2{\cdot}7 \times 10^2 : 4{\cdot}6 \times 10^6$, in good agreement with experiment. The Konopinski-Uhlenbeck expression, however, predicts corresponding ratios of $1 : 3{\cdot}8 \times 10^3 : 2{\cdot}7 \times 10^{10}$; here the end-points must be taken as 2250, 510 and 22kV. respectively, in order to obtain agreement with the shape of the β-spectra at lower energies.

Thus the Konopinski-Uhlenbeck expression is in marked discrepancy with observation. On the other hand, there is no doubt, as shown by Bethe and Bacher[4], that it gives a correct representation of the relative periods of β-decays of high energy, that is, with end-points between about 2 MV. and 12 MV.

The recent results of Lyman[5] now show that neither the Konopinski-Uhlenbeck nor the Fermi expression gives the correct shape of the β-ray spectrum for radium E or for radio-phosphorus, ^{32}P. It is possible, however, to obtain close agreement with his results by a linear combination of the two expressions each using the same high-energy end-point ε_0, taken as the energy of the fastest observed electrons. The shape of the spectrum is then given by

$$N\,d\varepsilon = F \times \left\{1 + \left(\frac{\varepsilon_0 - \varepsilon}{K}\right)^2\right\} d\varepsilon,$$

where N is the number of electrons with energy between ε and $\varepsilon + d\varepsilon$ in units of mc^2, and F is the value of N given by the Fermi expression alone.

To fit the results for radium E and ^{32}P, values of K of 1·4 and 2·2 mc^2 are required respectively. If this difference in K between the two disintegrations is connected with a difference in the matrix elements of the heavy particles rather than with the higher value of ε_0 for ^{32}P, then the value of K may be expected to be approximately constant for β-decays of the same type. For small ε_0 the term involving K will be small, so that for low-energy spectra the shape and the relation of the period and energy should be given by the Fermi expression. For high-energy spectra the shape (except near $\varepsilon = \varepsilon_0$) and the period should be given by the Konopinski-Uhlenbeck expression owing to the dominance of the second term.

Dissociation of Ovalbumin in Urea Solvent

THE physical molecule in solution is that unit which will acquire from thermal vibrations an average of 1/2 kT ergs of energy for each of three translational degrees of freedom. It is becoming increasingly evident that the weights of protein molecules defined in this way may change with solvent temperature, dielectric constant, protein or salt concentration, and other factors. Numerous studies from this Laboratory have demonstrated the effect of change of pH of the solvent medium in the dissociation and association of the molecules comprising the fundamental component.

In connexion with work on the physical chemistry of zein, observations have been made of the sedimentation velocities of the light, predominant, and heavy constituents of the normal zein. Aqueous alcohol (60 per cent) and urea (50 per cent) were used as solvents. The zein was always dissolved in the aqueous urea solution immediately before the centrifuging was begun, and the resulting sedimentation constants agreed with those found by using the alcoholic solvents. A preliminary report of this work has already appeared in NATURE[1].

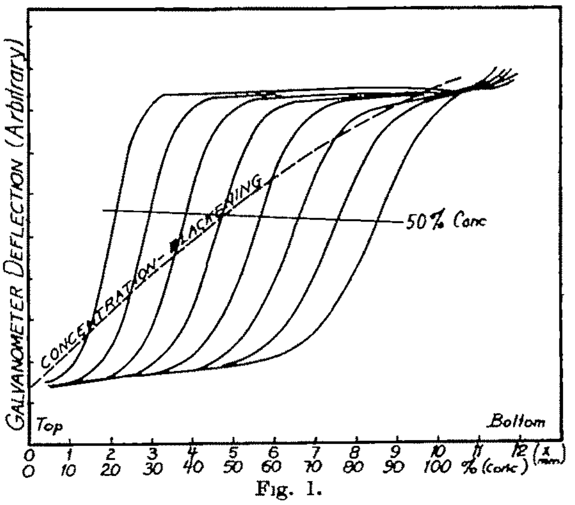

Fig. 1.

PHOTOMETER CURVES FROM SEDIMENTATION PICTURES OF OVALBUMIN IN AQUEOUS BUFFER SOLUTION, $pH = 6{\cdot}0$ ($0{\cdot}1\ m$ $NaCl$ + $0{\cdot}085\ m$ KH_2PO_4 + $0{\cdot}005\ m$ Na_2HPO_4). CENTRIFUGAL FIELD = 233,000 TIMES GRAVITY; EXPOSURE INTERVAL = 15 MIN. VISCOSITY RATIO = 0·810; $(1/v - \rho)$ RATIO (SEDIMENTATION 'DRIVING FORCE') = 1·027. $s_{20} = 3{\cdot}6 \times 10^{-13}$. IF SPHERICAL SHAPE IS ASSUMED, THIS CORRESPONDS TO $M = 36{,}000$.

At the time the use of urea as solvent for zein was begun, it was realized that this and other compounds containing nitrogen must influence, sooner or later, the condition of the protein in the solution. Accordingly, centrifugal studies were made of purified ovalbumin dissolved in aqueous urea (50 per cent). This protein was found to have been almost completely dissociated into a molecule having sedimentation constant $s_{20} = 2{\cdot}5 \times 10^{-13}$ cm./sec./dyne, so that the molecular weight of the product of dissociation is approximately a half that of the ordinary ovalbumin molecule. The effect of the urea solvent in dissociating the protein is shown clearly by Figs. 1 and 2, in which are presented sedimentation diagrams (light absorption method) for the normal ovalbumin in buffered aqueous solvent and for the dissociated ovalbumin in urea solvent. Sedimentation experiments were performed with the original ovalbumin in aqueous solution before and after the observations in the urea solvent.

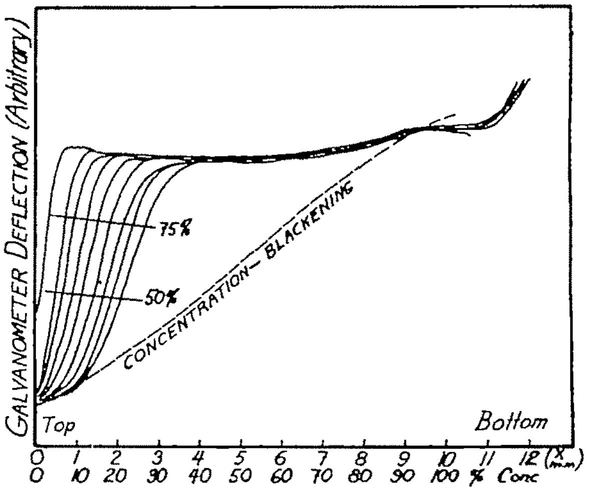

Fig. 2.

PHOTOMETER CURVES FROM SEDIMENTATION PICTURES OF OVALBUMIN AT ISOELECTRIC POINT IN 50 PER CENT UREA SOLUTION ($0{\cdot}1\ m$ KCl). CENTRIFUGAL FIELD = 220,000 TIMES GRAVITY; EXPOSURE INTERVAL = 23, 17, 20, 20 MIN.; VISCOSITY RATIO = 1·51 (AV) $(1/v - \rho)$ RATIO = 1·730. $s_{20} = 2{\cdot}5 \times 10^{-13}$. IF SPHERICAL SHAPE IS ASSUMED, THIS CORRESPONDS TO $M = 21{,}000$.

Further experiments were carried out to determine whether or not the dissociation is reversible. Purified ovalbumin was dissolved in the 50 per cent aqueous urea solution, and the resulting solution was placed in a collodion sack and dialyzed against $m/150$ phosphate buffer solution, $pH = 6$, to remove the urea. After a four-day period, the urea had been dialyzed out but a considerable portion (three fourths) of the ovalbumin had coagulated. The ovalbumin solution was then centrifuged. In spite of some inhomogeneity, the experiment demonstrated the presence of protein molecules having the same sedimentation constant as that of the original ovalbumin. Although this molecule, of normal sedimentation behaviour, must have been formed from the dissociated portions, we prefer to leave open for the present the question of the reversibility of the dissociation. Similar studies with several solvents, using observations of diffusion constants of the components to characterize the molecular species present, are now nearing completion, and we hope to give a complete answer to this particular question in the near future.

The experiments described above were performed during the spring of the academic year 1934–35. We wish to thank Prof. The Svedberg and his associates for their interest and assistance with the work.

Some Infra-Red Bands in the 3μ Region

IN view of recent communications[1,2,3] on the infra-red band arising from the O—H vibration in certain compounds, it is of interest to direct attention to certain analytical data obtained by us with comparatively high dispersion in the region 3μ, working with solutions about 0·1 mol/lit. in carbon tetrachloride.

In phenol, benzyl alcohol, diphenyl carbinol and triphenyl carbinol, we find that an intense O—H band is obtained in each case, the wave-length being highest for phenol (2·770 μ) and lowest for benzyl alcohol (2·764 μ). The association band[1] is found at 2·87–2·97 μ, the wave-length increasing with the intensity of the band; its shape as shown in Fig. 1 for benzyl alcohol is similar to that for ethyl alcohol in carbon tetrachloride[1]. The intensity of the association band was about the same for phenol and benzyl alcohol, was less for diphenyl carbinol, and with triphenyl carbinol was visible as a small 'hump' on the general absorption at 2·87 μ. These results suggest that the replacement of hydrogen by phenyl groups in benzyl alcohol suppresses intermolecular association.

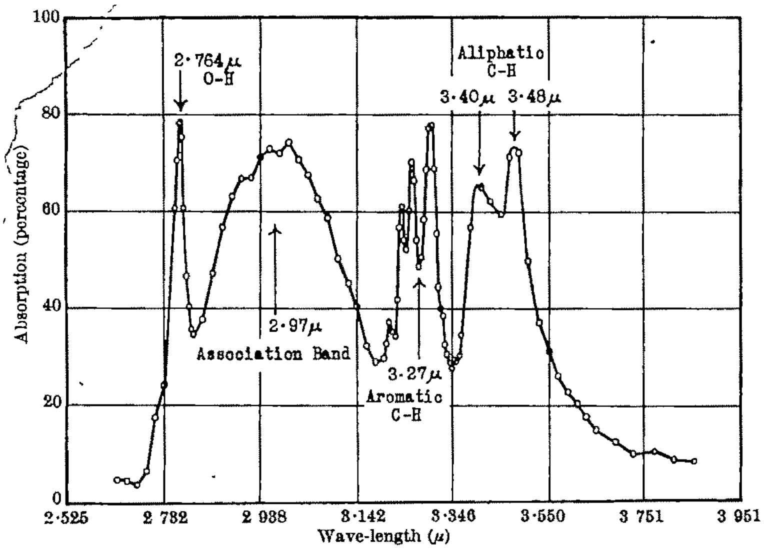

Fig. 1.

ABSORPTION OF A 1·3 MM. LAYER OF BENZYL ALCOHOL IN CARBON TETRACHLORIDE (0 169 MOL/LIT.) AT 18° C.

Dilution was found to reduce the intensity of the association band in the case of phenol much more rapidly than the O—H band (cf. Errera[2]). The former band dropped from 80 per cent absorption in 0·174 mol./lit. (O—H band 94 per cent) to 5½ per cent at 0·0145 mol./lit. (O—H band 58 per cent). The triphenyl carbinol showed 12·5 per cent for the association band at 0·066 mol./lit. as compared with 29 per cent for phenol at the same concentration.

Fig. 1 shows bands due to OH and association, the aromatic C—H bands around 3·27 μ and the aliphatic C—H bands at 3·40 and 3·48 μ.

A full account of the bands of these and other organic compounds will be described elsewhere.

A Possible Acid-Dissociation of Metal-Ammonia Ions, and its Bearing on Certain Reactions

RECENT observations[1] on exchange reactions between heavy water and cobaltammines suggest a possible mechanism for certain reactions of the latter.

It would seem that the ammonia molecules in these complexes must, by co-ordination, have lost the ability to form ammonium ions, and therefore if we assume that the exchange reactions take place through the D+ ion, we must conclude that these co-ordinated ammonia groups can dissociate as acids:

$$\mathrm{(Co.6NH_3)^{3+} \rightleftarrows (Co.5NH_3.NH_2)^{2+} + H^+} \quad (1).$$

This seems plausible, since the co-ordination of the analogous water molecule enables it, as is well known, to dissociate as an acid:

$$\mathrm{(Co.5NH_3.H_2O)^{3+} \rightleftarrows (Co.5NH_3.OH)^{2+} + H^+}; \quad k = 2 \times 10^{-6} \quad (2).$$

The corresponding dissociation constant for the co-ordinated ammonia molecule would presumably be much smaller, but might still be appreciable.

On this basis it would be possible to account for the rapid replacement of acido-groups by hydroxyl ions:

$$\mathrm{(Co.5NH_3.Br)^{2+} + OH^- \rightarrow (Co.5NH_3.OH)^{2+} + Br^-} \quad (3).$$

This reaction is unique, in that such replacements by other anions only take place much more slowly if at all. Alternatively, it may be regarded as catalysis by hydroxyl ion of an aquotization reaction,

$$\mathrm{(Co.5NH_3.Br)^{2+} + H_2O \rightarrow (Co.5NH_3.OH_2)^{3+} + Br^-},$$

followed by instantaneous establishment of the hydroxo-aquo equilibrium.

Now the kinetics of the aquotization of acido-aquo complexes have led to the conclusion[4] that the hydroxo-acido ion undergoes this change much more rapidly than the aquo-acido ion with which it is in equilibrium, presumably in virtue of its smaller positive charge—a conclusion which harmonizes with the general observation that diacido complexes undergo aquotization more rapidly than mon-acido complexes.

By analogy, then, the acido-hydroxo replacement first referred to might proceed as follows :

I. $(Co.5NH_3.Br)^{2+} \rightleftarrows (Co.4NH_3.NH_2.Br)^{+} + H^{+}$

II. $(Co.4NH_3.NH_2.Br)^{+} + H_2O \rightarrow (Co.4NH_3.NH_2.H_2O)^{2+} + Br^{-}$

III. $(Co.4NH_3.NH_2.H_2O)^{2+} + H^{+} \rightleftarrows (Co.5NH_3.H_2O)^{3+}$

IV. $(Co.5NH_3.H_2O)^{3+} \rightleftarrows (Co.5NH_3.OH)^{2+} + H^{+}$.

I, III, and IV represent instantaneously established equilibria, while II would be much more rapid than the 'spontaneous' aquotization of the bromo-pentammine ion. The whole process would give a velocity equation of the same form as that for the direct replacement by hydroxyl ion and would account for the unique behaviour of the latter in this respect.

F. J. GARRICK.

Inorganic Chemistry Department,
University, Leeds, 2.

[1] Erlenmeyer and Gartner, *Helv. chim. Acta*, 17, 1008 (1934); James, Anderson and Briscoe, NATURE, 139, 109 (1937).

[2] Brønsted and Volqubartz, *Z. phys. Chem.*, 134, 97 (1927).

[3] Brønsted and Livingstone, *J. Amer. Chem. Soc*, 49, 435 (1927).

[4] Brønsted, *Z. phys. Chem.*, 122, 383 (1926).

MR. GARRICK has very courteously allowed us to see the foregoing letter before publication, and indeed suggested that he would publish it only with our concurrence. This encourages us to give the following brief outline of certain results we have obtained during the last few months in our study of the rate of interchange between hexammine cobaltic chloride and heavy water, which have led us to precisely the same view of the basic reaction as that at which Mr. Garrick has independently arrived.

The direct exchange of covalently bound hydrogen for deuterium must necessarily involve high energies of activation. It must therefore be supposed that interchange reactions which proceed readily at room temperature proceed by way of the attachment of the deuterium ion, or of heavy water, to ions or co-ordinately unsaturated groups; in the latter case elimination of light water may complete the course of the reaction. In the case of hexammine cobaltic chloride, the nitrogen atoms of the ammonia groups are co-ordinately saturated, so that in our view interchange must pre-suppose either : (*a*) dissociation of an ammonia molecule :

$$[Co(NH_3)_6]^{3+} \rightleftharpoons [Co(NH_3)_5]^{3+} + NH_3,$$

followed by interchange of the hydrogens of that ammonia through addition of water, or (*b*) an ionic dissociation

$$[Co(NH_3)_6]^{3+} \rightleftharpoons [Co(NH_3)_5NH_2]^{2+} + H^{+}$$

such as Mr. Garrick also supposes.

The great stability of the hexammine cobaltic ion toward acids rules out possibility (*a*), so that we envisage the mechanism of hydrogen interchange on the scheme (*b*) as given by the following reactions :

(1) $[Co(NH_3)_6]^{3+} \rightleftharpoons [Co(NH_3)_5NH_2]^{2+} + H^{+}$

(2) $[Co(NH_3)_5NH_2]^{2+} + HDO \rightarrow [Co(NH_3)_5NH_2D]^{3+} + OH^{-}$

(3) $H^{+} + OH^{-} \rightleftharpoons H_2O$

Reactions (1) and (3), as ionic equilibria are sensibly instantaneous; reaction (2) is the step determining the rate of reaction.

We are led on this basis to an expression for the velocity constant

$$K = \frac{1}{t} \cdot \frac{[H^+]}{[A]^{\frac{1}{2}}} \frac{[HDO]_\infty}{\xi_0} \cdot \log_e \frac{[HDO]_\infty}{[HDO]_\infty - [HDO]}$$

in which [A] = concentration of hexammine cobaltic chloride,

ξ_0 = initial 'heaviness' of the cobalt-ammine,

$[HDO]_\infty$ = concentration of heavy water after complete interchange,

[HDO] = concentration of heavy water at the time *t*.

This particular form of the expression is adapted to the conditions of our own experiments, in which we have found it convenient to reverse the normal procedure by measuring the rate of interchange between heavy cobaltammine and light water.

In agreement with the above expression, we find that (*a*) the rate of interchange varies inversely as the hydrogen ion concentration ; (*b*) for constant [A], the rate of interchange is independent of the heaviness ξ_0 of the salt ; (*c*) for salt of a constant heaviness ξ_0, the rate of interchange varies inversely as $[A]^{\frac{1}{2}}$.

The underlying hypothesis of the ionic dissociation of the ion $[Co(NH_3)_6]^{3+}$ appears therefore to be substantiated. Further aspects of this, and in particular the significance of the term $[A]^{\frac{1}{2}}$ in the above expression, we hope to discuss in presenting our detailed results.

We would add that the velocity of interchange in unbuffered solutions indicates an acidity constant K_a about 10^{-12}–$10^{-11 \cdot 5}$ for the hexammine cobaltic ion.

Calculation of Constants for Band Spectra

IT has not infrequently proved difficult in the analysis of spectra to decide which of two or more sets of constants refer to the deepest-lying energy states : an example of this arose in my experience in the interpretation of Gale and Monk's work on the fluorine di-atom FF. Empirical methods of obtaining these numbers for ground states may therefore be useful. It is already possible on the basis of the periodic classification of di-atoms[1] to form estimates of such numbers in many cases. The fundamental nuclear vibration frequency ω_e is one of the most important of these constants, since it enters into the expressions for other numbers. Methods by which the equilibrium internuclear distance r_e may be obtained from ω_e have been recently improved[2].

It has so far proved practicable to derive an empirical formula for ω_e's of di-atoms XX, XY and YY, so that if any two are known the third may be derived, but *only so long as X and Y contribute equal numbers of valency electrons to the shared group of XY*, or, in other words, so long as X and Y belong to the same atomic periodic group. In terms of the proposed classification, the di-atoms XY must be chosen from the *symmetrical* molecular groups designated II, IVs, VIs, VIIIs, Xs, XIIs and XIV[1]. For such cases, Howell[3] and I[1] independently observed that $a = \omega_e(XY)$ is approximately the arithmetic mean of $b = \omega_e(XX)$ and $c = \omega_e(YY)$, so that—

$$a = 0 \cdot 500(b + c) \quad . \quad . \quad . \quad . \quad (1)$$

As it turned out that the errors in a using (1) were always positive, I suggested[1] a reduction of 1·8 per cent in a, giving—

$$a = 0{\cdot}491(b+c) \quad . \quad . \quad . \quad . \quad . \quad (2)$$

It seemed probable that a more accurate formula could be reached by assuming that the contributions made by b and c to a might be unsymmetrical, the larger frequency c having a greater influence than the lower frequency b. Proceeding by empirical methods, I have searched for a better relationship on this basis, and have derived the following:

$$a^3 = 0{\cdot}800bc^2, \quad . \quad . \quad . \quad . \quad . \quad (3)$$

which appears to give remarkably reliable results.

Calculation from the available data on 36 di-atoms of the specified type, where a, b and c are known, shows that the average difference errors, neglecting sign, between a(calc.) and a(expt.) are 15·0, 9·8 and 3·8 wave-numbers by the three formulæ (1), (2) and (3) respectively. The corresponding percentage difference errors are 4·6, 3·3 and 1·6 per cent respectively. Judged either way, (3) gives the best results; moreover, the errors are no longer wholly positive. It may be added that in some cases the experimental uncertainty in a may amount to 1 or 2 per cent. If we may therefore trust this formula, it becomes possible to estimate a's for a score of di-atoms for which no definite experimental data are available.

The results seem to support Howell's view[3], that it is not very probable that a(PN), assigned by Curry, Herzberg and Herzberg, refers to the ground state. If, as may appear, the true value lies in the region 1,500 wave-numbers, my earlier arguments[4] about PN are in no way invalidated. In the case of AsN, the run of the numbers suggests that neither the assigned a(AsN) nor a(AsAs) belong to the unexcited condition. I cannot concur, however, in the suggestion[5] that the bond (force) constants k_0 of a triad of di-atoms of the specified kind are equal. In the course of calculations involving a considerable number of these constants, I found, for example, that the k_0's of OO, SO and SS were 117·7, 78·8 and $49{\cdot}7 \times 10^4$ dynes per cm. respectively[6].

The limitation observed in this note to symmetrical di-atoms appears to emphasize the suggested periodic group classification of molecules, as of considerable assistance in the discussion of band spectral data. For di-atoms other than those of the chosen groups, the errors are usually large, and equations of the present type useless. (A possible exception may be CP, where I am inclined to regard the coincidence as accidental). It seems probable that the 'reduced' mass will enter into suitable expressions for di-atoms of unsymmetrical groups, and efforts will be made to find a suitable formula of more general application on these lines.

I would be pleased to be of any possible assistance to workers who are interested in a particular estimate.

Details of the calculations here reported will be published in another place.

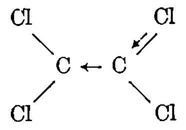
Force Constants and Structure

IN a recent letter in NATURE[1], Duchesne has discussed the values of the 'force constants' of the potential energy function of the molecules ethylene and tetrachlorethylene, and has attempted to draw inferences from the calculated data about structural properties. In a paper at present in the press[2], we have examined the values of the force constants of the linkages in different molecules of a given series, such as the methyl and ethyl derivatives of a metal, in so far as these are given by the values of their normal vibration frequencies. The results suggested that in different molecules of a particular type variation in the force constant of a given link or of the 'bending constant' of a given angle might throw light on the electronic arrangements in the different linkages. We have accordingly now calculated the force constants of linkages in a very large number of molecules from the known vibration frequencies. It becomes clear that in some cases, structural problems, such as the phenomenon of resonance, may be studied by this procedure. The detailed results will appear shortly elsewhere, but since our conclusions with the two molecules mentioned above appear to go further than those given by Duchesne, it may be fitting to summarize them here.

For ethylene we find: $k_{\mathrm{C-C}} = 9{\cdot}0 \times 10^5$, and $k_{\mathrm{C-H}} = 4{\cdot}85 \times 10^5$. For tetrachlorethylene: $k_{\mathrm{C-C}} = 5{\cdot}8 \times 10^5$ and $k_{\mathrm{C-Cl}} = 5{\cdot}2 \times 10^5$. Now for methane, we have $k_{\mathrm{C-H}} = 4{\cdot}98 \times 10^5$, and for carbon tetrachloride $k_{\mathrm{C-Cl}} = 4{\cdot}38 \times 10^5$ dynes per cm. Thus in passing from ethylene to tetrachlorethylene the constant of the C–C link is markedly diminished. This suggests the possibility of structure



agreeing with the idea of Duchesne. On this basis we should perhaps expect an increase in the C–Cl constant, as compared with that in carbon tetrachloride. This increase is noticed. The C–H constant, however, does not appreciably change in passing from methane to ethylene, since the hydrogen atoms have no electron donating capacity.

In the same way, cyanogen chloride might be written

$$\mathrm{Cl} \rightleftarrows \mathrm{C} \rightleftarrows \mathrm{N},$$

and the C–Cl constant ought to exceed the value in carbon tetrachloride. This is again found, the values being 5·15 and $4{\cdot}38 \times 10^5$. The C–N link constant, on the other hand, should be lower in cyanogen chloride than in hydrogen cyanide, as it is in fact, the values being 16·65 and $17{\cdot}8 \times 10^5$. Precisely similar results are found with cyanogen bromide and carbon tetrabromide.

Thus it is clear that calculations of this kind may well be instructive in connexion with structural problems. Some anomalies are found, however, which may arise from defects in the potential energy functions used. These will be discussed fully elsewhere, but it should be noticed that in the case given above (ethylene and tetrachlorethylene), regardless of the type of potential function used (valency force system, central force system, Delfosse[3] function), the C–C constant has approximately the same value, and changes in the same way and to approximately the same extent. This is strong indication of the reality of the effect suggested.

The corresponding variations of the bending constants of the angles is also interesting, as well as translation of the deduced force constants into distances by the method of Badger[4], but these will be fully given later.

Dipole Moments of some Aliphatic Aldehydes

SEVERAL determinations of the moments of aliphatic aldehydes have been made, but some uncertainty in the values exists.

The results previously published are given below.

Compound	Moment	Temperature	Solvent	Reference
Acetaldehyde	2·72	16°C.	(vapour)	1
	2·69	27°–182°	(vapour)	2
Propionaldehyde	2 4	—	benzene	3
n-Butyraldehyde	2·46	18°	benzene	4
n-Heptylaldehyde	2·56	22°	benzene	5

The values of the moments are given throughout in Debye units

The ease with which these compounds are oxidized and also the volatility of the lower members makes solution measurements difficult, and an accurate comparison of the moments cannot be made, as the results are incomplete. We are therefore reinvestigating these compounds, and preliminary measurements in benzene solution have been completed.

The moments of acetaldehyde, propionaldehyde, valeraldehyde and isovaleraldehyde are, we find, 2·49, 2·54, 2·57 and 2·60 respectively in benzene solution. The compounds were fractionated and measured in an atmosphere of nitrogen and the dielectric constants of the solutions determined by the apparatus described by Martin and Partington[6].

The physical constants of the materials, and the values of the polarizations and moments determined in benzene solution at 20°, are given below.

Compound	b p	d_4^{20}	n_D^{20}	P_E	$P_{2\infty}$	μ
Acetaldehyde	20 6° C./764 mm	0 8058 (0°)	1 3437 (0°)	11 5 c c.	143 c.c	2 49
Propionaldehyde	48 2° /764	0 8058	1·3639	16 0	153	2 54
n-Valeraldehyde	102 5° /766	0 8105	1·3947	25 5	165	2·57
iso-Valeraldehyde	92 5° /754	0·8004	1·3904	25 5	169	2 60

Further work on other aldehydes is in progress, and the results will be discussed when completed.

Insect Drift over the North Sea

FROM August 5 until August 13 last year, one of us (A. C. H.) was kindly permitted to accompany the Ministry of Agriculture and Fisheries research ship *George Bligh* during one of her routine cruises over the North Sea and, by flying collecting nets either from the mast-head or from kites flown from the ship, to study the drift of insects over the sea. It is hoped that further surveys will be made this year. Whilst a full discussion of the data will be reserved until further evidence is available, the results of this first survey were so unexpected that a preliminary note may be of interest.

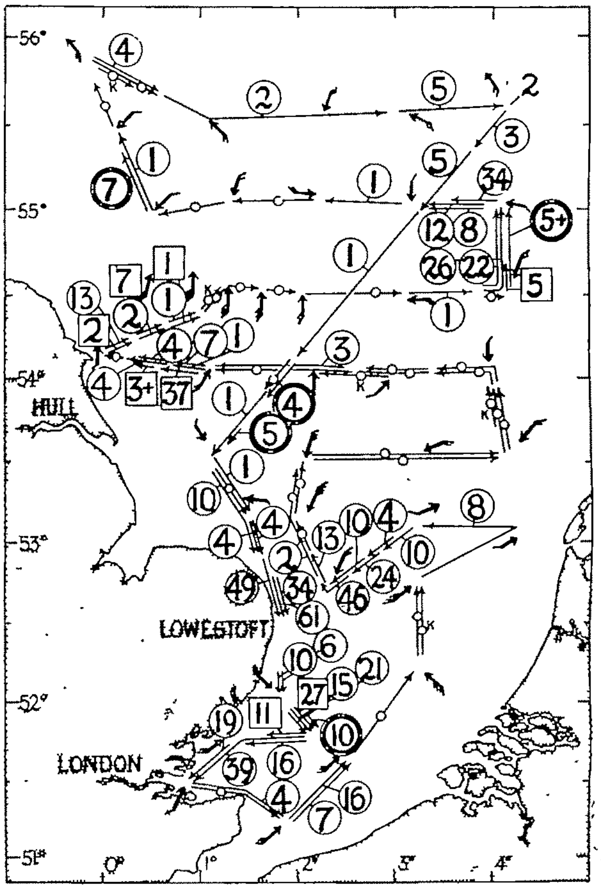

Fig. 1.

CHART SHOWING INSECT CAPTURES OVER THE NORTH SEA.

Fig. 1 is a chart of the area covered. Each of the fine arrows shows the direction and distance over which a net was collecting. The nets were flown almost continuously, so that by following the arrows one may follow the track of the ship starting from Lowestoft in a southerly direction. A small circle on an arrow indicates a blank haul. Arrows side by side indicate nets collecting at the same time. The enclosed figures against the arrows show the total number of insects taken in each net. Those in circles were from nets flown from the mast-head, about 40 ft. above sea-level, those in squares from nets flown from kites at heights between 200 ft. and 400 ft. Blank kite hauls are marked with a 'K.'

The nets were of muslin with an opening of 3 ft. diameter, except when occasionally a larger net, 6 ft. diameter, was used (shown by a double circle). A glass collecting tube was fitted to the end of each net; twice these broke, presumably losing most of the catch (indicated by + sign on chart).

Altogether 730 insects were collected, distributed amongst the following families thus:

HEMIPTERA		DIPTERA	
Aphididæ	171	Cecidomyidæ	21
Psyllidæ	1	Chironomidæ	54
NEUROPTERA		Culicidæ	1
Chrysopidæ	1	Mycetophilidæ	53
Hemerobiidæ	2	Psychodidæ	20
TRICHOPTERA	1	Phoridæ	3
LEPIDOPTERA		Syrphidæ	7
(Noctuidæ	1)	Acalypteræ	355
Micro-lepidoptera	5	Spiders	6
HYMENOPTERA			
Chalcidoidea	5	Unrecognizable	
Ichneumonoidea	7	(damaged in net)	16

The broad arrows on the chart indicate the direction of the wind at points where the ship stopped for marine work, and the number of 'feathers' on the arrows indicate the strength of the wind by the Beaufort scale: 1, 2, 3 or 4. The speed of the ship was approximately 8 knots.

The insects taken in the north-eastern area, mostly Aphididæ and small Diptera but also lacewing flies and micro-lepidoptera, were 120–150 miles from the nearest land.

There is, on the whole, no apparent difference between the number of insects taken at the mast-head and at heights of 200–400 ft. in the kite nets. Considering the small size of the nets used, the number of insects collected indicates a very large population of 'aerial plankton' drifting across the sea. All were taken in the nets except the Noctuid *Plusia gamma* and one Hemerobiid, which flew on board ('2' at north-east corner of chart), and all except the Noctuid must be regarded as too small and weak in flight to be true migrants. All observed in the collecting tubes (the majority) were alive and active; a few were crushed in handling the nets, especially when wet through fog. They were taken both during the day and night, and some in rain or fog.

Distinct areas can be seen in the chart: richer, poorer or apparently devoid of insect life. The barren areas perhaps represent blocks of air which have moved off the land during the night when convection currents are at a minimum.

It appears likely that the study of insect drift over the sea, in giving definite evidence of the distances (minimum when measured from nearest land) travelled by insects, may be of value in understanding the spread of insect pests over the land, in addition to indicating the infection of Great Britain from the Continent and throwing light on the origin of the insect faunas of islands. It is hoped that with the co-operation of steamship lines across the North Sea and Channel, a regular survey may be inaugurated.

A Comparison of Certain Properties of Timbers from Tropical and North Temperate Regions

EXAMINATION of the results of standard mechanical tests on more than three hundred species of timber reveals a striking difference in the properties of timbers from tropical and north temperate regions respectively. The results were taken from tests carried out in the Timber Mechanics Section of this Laboratory, together with those published by the Forest Research Institute, Dehra Dun, India[1], and the United States Forest Products Laboratories, Madison[2].

Two strength properties of the timbers were considered, namely, the strength in impact bending as measured by the maximum drop of a 50 lb. hammer, and the strength under compression parallel to the grain. When the species-averages of these two properties were plotted separately against specific gravity, it was observed that for both of them the values for tropical and north temperate zone timbers have quite distinct distributions. Although these distributions overlap, it is clear that, for any given specific gravity, tropical timbers are, on the whole, weaker in impact bending though stronger under compression parallel to the grain than north temperate zone timbers.

There appear to be no constant differences in gross anatomical structure between temperate and tropical timbers such as might account for the observed differences in their strength properties, and it would seem that the causes must lie in the composition of the cell walls. A comparative study of thin transverse sections of species from each group indicated that, on the average, the fibres of the temperate zone timbers show a greater affinity for the so-called cellulose-stains (for example, Light Green in a Safranin-Light Green combination), particularly after the sections have been subjected to prolonged boiling in distilled water, whereas the tropical timbers usually show a stronger reaction with so-called lignin reagents (for example, Phloroglucin). Furthermore, a comparison of six English-grown timbers with material of the same or closely related species grown in the tropics revealed a somewhat greater affinity for so-called cellulose stains on the part of the English-grown specimens.

Although the reactions of these microstaining reagents are not closely related to the results of standard chemical analyses of woody tissues, it may be inferred that variations in the concentration of some substance or in the physical condition of the cell walls affect the two strength properties in different directions. It is interesting to note that the positive relation between strength in impact bending and under compression parallel to the grain is an indirect one, since both strength properties are positively related to specific gravity. Mr. E. D. van Rest, of this Laboratory, has demonstrated statistically that the indirect positive relation masks a significant negative relation between the two types of strength.

The investigation so far has been of a preliminary nature and it is hoped to publish the complete results later; the evidence already obtained, however, strongly suggests that the influence of tropical conditions of growth on the composition of wood cell walls is such that, where weight is the primary consideration, timbers of outstanding toughness must be sought in the temperate regions, as they are not likely to be produced under tropical conditions.

Urea as a Hygroscopic Substance

WHILE pure urea shows no tendency to absorb moisture when exposed to air under ordinary conditions, it becomes a remarkably hygroscopic substance if the humidity of the air is at a relatively high level. It is only recently that American chemists from the Bureau of Chemistry and Soils, Washington, D.C., have directed attention to this phenomenon in connexion with the behaviour of urea when present as a constituent of various mixed fertilizers.

Adams and Merz[1] have shown that while pure urea becomes hygroscopic only when the relative humidity of the air is at 72·4 per cent (at 30° C.), mixtures with various salts give rise to products which become hygroscopic when the relative humidity of the air is at a much lower level. They found, for example, that a mixture of equimolecular proportions of urea and ammonium nitrate became hygroscopic at a relative humidity of 18·1 per cent, whereas pure ammonium nitrate itself only becomes hygroscopic at a relative humidity of 59·4 per cent.

While the American investigators[2,3] have been mainly concerned in determining the effect of urea on the hygroscopicity of mixtures with various salts used as fertilizers, no results have been hitherto recorded as regards the maximum amount of water which urea can absorb when exposed to an atmosphere at its maximum hygrometric state. In order to obtain information upon this point, the following experiments were made: A small quantity (0·6 gm.) of pure dry urea in fine powder was spread over the surface of a watch-glass, which was supported over a dish containing 30 c.c. of water. The whole was covered with a beaker so that the connexion with the outer air was confined to a small opening due to the lip of the beaker. The temperature during the experiments averaged 16° C.

The results, which are of a remarkable nature, were as follows:

Time (hours)	Water absorbed (per cent)	Time (hours)	Water absorbed (per cent)
1	4·23	96	111·48
24	31·70	144	145·40
48	49·73	168	166·60
72	77·70	192	176·06

Thus after a period of eight days, after which there was no further increase in weight, urea had absorbed slightly more than one and three-quarter times its own weight of water. At the end of three days, the urea had completely dissolved in the absorbed water, yet the solution continued to absorb considerably more water than occurred up to this time. This is remarkable for a substance that separates from aqueous solution in the anhydrous form. Repetition of the experiment with urea in coarse powder and as crystals gave 174·8 per cent and 173·9 per cent absorption respectively, when equilibrium had been established with the surrounding atmosphere.

It is very remarkable that urea, which is non-hygroscopic until the relative humidity of the air reaches 80 per cent at 15° C. (Adams and Merz), should show such a great avidity for water when placed in a saturated atmosphere. In this connexion the contrast in the behaviour of (*a*) urea, (*b*) urea hydrochloride, and (*c*) urea nitrate is of interest. Equal weights of the three well-dried substances were exposed on watch-glasses on the laboratory bench, and whereas (*a*) and (*c*) showed no increase in weight after exposure for six days, (*b*) absorbed 53·5 per cent of water after only 24 hours exposure. Furthermore, (*c*) showed no increase in weight when exposed for six days in a saturated atmosphere under the conditions of the experiment with urea. Thus we have urea hydrochloride very hygroscopic even at a low relative humidity, urea itself hygroscopic only when the relative humidity is very high, and urea nitrate non-hygroscopic even when exposed to air saturated with water vapour. Can the physical chemist offer any explanation to account for these phenomena?

The subject is one which seems to be well worthy of a more extensive investigation, and this is the chief reason for bringing the foregoing results to the notice of those who may be interested in the matter.

Structure of Agar-Agar

WE now communicate some preliminary results of the investigation on methylated agar prepared from the acetate previously described in NATURE[1]. By the simultaneous deacetylation and methylation of acetylated agar ($[\alpha]_D^{15°} = -32°$ in chloroform; $CH_3CO = 38·5$ per cent), an apparently homogeneous methylated agar was obtained ($[\alpha]_D^{15°} = -78°$ in chloroform; $OCH_3 = 31$ per cent), the methoxyl content of which remained constant despite repeated methylations.

This derivative on hydrolysis yielded a mixture of methylated sugars (yield *c.* 75 per cent), together with an acid. The sugars on conversion into the glycosides yielded a new crystalline trimethyl α-methylgalactoside (yield, *c.* 70 per cent) from which on complete methylation and suitable treatment crystalline tetramethyl *d*-galactopyranose anilide was obtained in excellent yield, indicating the absence of substitution in position 5 of the trimethyl galactose molecule. This sugar gave a crystalline dimethyl galactose phenylosazone indicating substitution in position 2, and oxidation with bromine under conditions favourable to the formation of a γ-lactone yielded a trimethyl galactonolactone of high positive rotation ($[\alpha]_D^{18°} = +150°$ in water), which fell rapidly on standing to an equilibrium value of + 50° in less than 24 hours, this behaviour being characteristic of a δ-galactonolactone. Furthermore, galactoside formation at room temperature regenerated exclusively the galactopyranoside, so that there appears to be no doubt of the fact that position 4 is occupied by a methoxyl residue, and the trimethyl galactose cannot therefore be the 2 : 3 : 6-trimethyl galactose isolated from varianose by Haworth, Raistrick and Stacey[2]. There thus exists the possibility that the methylated sugar in question is 2 : 3 : 4- or 2 : 4 : 6-trimethyl galactopyranose. The former has been previously described [3,4]; but both the properties of the lactone and its derivatives and the results of oxidation with nitric acid indicate that the latter formulation is correct in this case.

In view of these facts therefore, and the strong negative rotations of acetylated and methylated agar, we consider it probable that the 'main carbohydrate portion' of agar-agar consists of β-galactopyranose units linked at positions 1 and 3, an arrangement unique so far in polysaccharide chemistry. From an inspection of models it appears either that the galactopyranose units are present in the form of a six-membered ring, or alternatively as a zigzag chain terminated by residues as yet undetermined. It is not yet possible to form an opinion on the 'fine structure' of the agar macro-molecule, whether for example the supposed sulphuric ester residues exist as cross-linkages, or indeed their approximate location. Further work will also be necessary to decide the constitution and mode of union of the acid portion of the hydrolysed product.

These investigations will be discussed elsewhere.

The Theory of Dimensions

IN reviewing Dr. F. W. Lanchester's book "The Theory of Dimensions and its Application for Engineers" in NATURE of January 9, I stated with regard to Appendix VI that "in my opinion the author was unwise to include this section in a book the avowed object of which is to help the young engineer". Dr. Lanchester has written to me pointing out that although this was the primary object of writing the book, it is stated in the preface that the author hopes that it "may be found of service to others besides those to whom it is primarily addressed. As a book of reference for workers in the physical laboratory, auxiliary to existing works on the same subject, it may prove of service as conveying its message in a simple and direct manner".

I should be sorry if the book were prejudiced in any way by my reference to what was only the primary object as the avowed object. In an editorial reference to the book in the *Wireless Engineer*, I remarked that "like many another book written avowedly for the young, it will be read with enjoyment and profit by many who are no longer young; in fact, the latter class of reader will be better able to appreciate the vigorous attempts to extirpate dimensional heresy—that is, anything with which the author does not agree".

University,
Glasgow.

Points from Foregoing Letters

THE effect of substituting deuterium for hydrogen on the intermolecular bonds of oxalic acid has been examined by Dr. J. Monteath Robertson and A. R. Ubbelohde using X-ray methods. A small expansion of the lattice occurs, mainly in the direction of the deuterium bonds, an effect which throws light on the mechanism of the hydrogen bond, and promises to be of value in locating certain types of hydrogen linkage in complex structures.

In order to predict the shape of the curve expressing the energy distribution of the electrons emitted in radioactive transformations, several formulæ have been proposed, based on the theory that (unobservable) neutrinos are simultaneously emitted. Dr. H. O. W. Richardson points out that the equation of Fermi fits low-energy transformations, whilst that of Konopinski-Uhlenbeck applies in the case of high-energy electrons.

Diagrams of the rate of sedimentation of ovalbumin in water solution (buffered at pH 6·0) and in 50 per cent urea solution, are given by Prof. J. W. Williams and Dr. C. C. Watson. The data indicate that, in urea solution, the ovalbumin is dissociated into a product of approximately half the molecular weight in water solution. This dissociation appears to be reversible.

The presence of an absorption band in the region of 2·7 μ in various organic compounds containing O—H groups is discussed by Dr. J. J Fox and Dr. A. E. Martin. A curve showing the infra-red absorption of benzyl alcohol in carbon tetrachloride, showing both the O—H absorption band and the 'association' band is submitted. The authors state that replacement of hydrogen by phenyl groups suppresses intermolecular association.

Dr. J. S. Anderson, N. L. Spoor and Prof. H. V. A. Briscoe report that the rate of interchange between water and hexammine cobaltic chloride containing deuterium is independent of the heaviness of the salt at any given concentration, and for salt of given heaviness varies inversely as the hydrogen ion concentration and inversely as the square root of salt concentration. These facts suggest the explanation (independently reached by F. J. Garrick) that co-ordinated ammonia can undergo an acid dissociation of the type

$$[Co(NH_3)_6]^{3+} \rightleftarrows [Co(NH_3)_5NH_2]^{2+} + H^+.$$

Dr. C. H. Douglas Clark has reviewed methods available for the calculation of the band spectral constants of di-atoms, and has introduced a formula connecting the fundamental vibration frequencies a, b and c of members of a diatomic triad XY, XX and YY, respectively, which belong to 'symmetrical' molecular groups, as follows: $a^3 = 0{\cdot}8bc^2$.

Tropical timbers show on the whole less resistance to impact, though greater strength under compression parallel to the grain, than north temperate zone timbers of the same specific gravity. S. H. Clarke suggests that the differences in strength properties are caused by growth conditions acting through the medium of the cell wall composition.

Prof. E. A. Werner directs attention to the fact that urea, a non-hygroscopic substance under ordinary conditions, can absorb one and three-quarter times its weight of water when exposed to air saturated with moisture. This rather remarkable result for a substance which separates from aqueous solution in an anhydrous form is discussed in connexion with the marked contrast in the behaviour of urea, urea hydrochloride and urea nitrate towards water absorption under similar conditions.

The hydrolysis of completely methylated agar-agar yields as the main product a trimethyl galactose which appears to be 2 : 4 : 6-trimethyl galactose. Dr. E. G. V. Percival, Dr. J. Munro and J. C. Somerville consider it probable therefore that portion of the polysaccharide which is derived from galactose is composed of β-galactopyranose units linked at positions 1 and 3.

Research Items

Malay Magic

THE various classes of the magical dance performed in the Malay Peninsula, notwithstanding innumerable variations in character and underlying principle, present a general uniformity of type, while the associated traditions conform to certain common patterns. Details of the dance and the magical beliefs connected with it in the State of Kelantan studied by Jeanne Cuisinier (*Inst. d'Ethnol. Trav. et Mém.*, 22) were corroborated by the author in Perak, Pahang and Trengannu, as well as in Patani, Siam. In these dances, the spirits, especially the ancestral spirits, are invoked for a variety of purposes, mostly connected with the treatment of disease, especially epidemics. The performers fall into the possessive trance characteristic of this type of dance. In order to understand the character of the dances, it was found necessary to study the whole nexus of magical belief, on which they rest. Observations of the unbalanced mentality characteristic of those subject to supernatural influence were recorded, though without any attempt at psychological diagnosis, owing to the author's lack of medical training. The essential conditions in the 'make up' of the medicine-man belief in Malaya are: revelation, heredity and secrecy; while symbolism plays a large part in magical practice. Revelation may be either voluntary and induced, or involuntary. The voluntary revelation is sought by going into retreat, fasting, prayer, etc. Involuntary revelation is most commonly found in members of families in which sorcery is hereditary, going back to remote ancestors—a matter in which it links up with totemism. Secrecy is maintained, even when incantations have to be uttered aloud, by speaking in a peculiar and incomprehensible voice or by omitting part of the charm, until it is reduced to perhaps no more than one or two words.

A Peruvian Manuscript

IN 1908 Richard Pietschmann, director of the Gottingen Library, when attending as German delegate the xvth International Congress of Orientalists at Copenhagen, discovered in the Royal Library the manuscript, hitherto unnoted, of a chronicle written by a Peruvian, Don Felipe Guaman Pomo de Ayala. This manuscript, consisting of 1,174 pages quarto, it was Pietschmann's intention to publish with commentary; but he died before his work was complete. It is now published in facsimile by the Institut d'Ethnologie of Paris (*Trav. et Mém.*, 23). The chronicle, which is in corrupt Spanish interspersed with many Quichua words, was written in the early years of the seventeenth century—it embodies a letter by the author's father, which is dated 1587. Guaman claimed to be a descendant of the rulers of the powerful northern State, which long resisted the power of Cuzco. Whatever his descent, his circumstances were abject, a condition which he attributes to his devotion to the cause of his fellow countrymen. About one quarter of the manuscript is devoted to a description of the country and its inhabitants before the conquest by Francisco Pizarro, in which the historic period is preceded by four legendary epochs, beginning with that of the divine, or semi-divine Viracocha, followed by those of the authochthones or "giants", the men of the desert, and the warriors. Historical and biographical sketches and an account of the Inca constitution and social orders follow. The story of the acts of the conquistadores and the rule of the viceroys, Indian risings and sufferings, is rounded off by an idealistic sketch of Indian Christendom, and the Indian calendar of agricultural operations. The remarkable and most valuable feature of the manuscript, overshadowing the text, is the very large number of full page drawings, illustrating the narrative, which convey much information throwing light on Indian appearance, vocabulary, dress, custom and belief.

Birds of the South Orkney Islands

THERE are no truly resident birds in the South Orkney Islands, and very few are to be seen in winter, although one or two sheathbills, thanks to their omnivorous diet, find it possible to live through the winter months upon the refuse of human habitations in the neighbourhood of the meteorological station, as they did about the winter quarters of the *Scotia* expedition. In the "Discovery Reports" (12, 349; 1936) R. A. B. Ardley gives an account, illustrated by eight photographic reproductions, of the members of this oceanic bird fauna, supplementing the description of plumage and breeding given by Dr. Eagle Clarke in his account of the *Scotia* material, and adding records of the presence of several species from islands in the group not investigated by the Scottish National Antarctic Expedition.

Marine Research at Millport

THE annual report of the Scottish Marine Biological Association for 1935–1936 shows that a large amount of good work has been accomplished. Research on herring by Drs. Orr, Marshall and Nicholls is progressing, but, as is usually the case with trying to rear herring from artificial fertilizations, the young only lived about three weeks. Various growth stages, however, were obtained from the plankton, and both larval and metamorphosed fish studied. From hatching to metamorphosis they grew rapidly and fairly regularly, increasing in length 2–3 mm. weekly. Metamorphosis began at a little over 40 mm. At hatching, a single larva weighed about a fifth of a milligram, at a length of 20 mm., reached when the fish was about five weeks old, it weighed 1¼ mgm.: and at 40 mm. when about twelve weeks old, 35 mgm. Estimations of fat and protein were made, the fat content increasing rapidly as the fish approached metamorphosis. Vertical hauls for plankton were taken whenever the young herring were caught. The food eaten by the fish corresponded in size with the size of the fish, as is usually found. The smallest were eating small *Pseudocalanus*, *Microcalanis*, etc., and the larger were eating adult *Pseudocalanus*, *Centropages*, *Temora*, etc. Dr. Marshall is continuing her work on the biology of the small copepods and Dr. Orr his work on the composition of the food of fish by making analyses of the chemical composition of numerous species of crustaceans, molluscs, echinoderms, worms, etc.; Dr. Nicholls his study of the copepod genera *Leptosyllis* and *Paramesochra*, and Dr. A. C. Stephen has paid special attention to the spat-falls of *Tellina tenuis*, continuous observations having been made since the autumn of 1926. Dr. D. C. Gibb has carried out an ecological survey of marine algæ of an area of coast at the north end of Cumbrae.

Boll-worms of Cotton in South Gujerat

MESSRS. B. P. DESHPANDE and N. T. Nadkarny have examined methods for controlling the two species of spotted boll-worms, *Earias faba* and *E. insulana* in south Gujerat, Bombay Presidency. The results of their investigations have been published as Scientific Monograph No. 10 (1936) of the Imperial Council of Agricultural Research, India. Various methods of controlling the larvæ of these two moths are discussed, and the results of experiments recorded. It appears that no advantage is likely to be derived from biological methods of control since all the known parasites of *Earias* are found to be present locally. A study of the most important parasite, *Microbracon lefroyi*, also showed that it was not possible to increase the incidence of this species by artificial methods. Advantage has been taken of the fact that the larvæ of *Earias* get their supply of food, between the two cotton-growing seasons, from the fresh shoots sprouting from standing plants of cotton or their stumps, and from stray malvaceous weeds. The authors claim that it will be possible to prevent the carry over of the *Earias* from one season to another by the destruction of cotton plants and weeds at the appropriate time and by withholding the cultivation of 'bhindi' during that period since it is also used as a food plant by the larvæ. A clean-up scheme has, therefore, been started in order to determine the efficacy of the proposed measures, and is still in progress. The scheme, it may be added, is being financed by the Indian Central Cotton Committee.

Hæmostatic Action of Ayapin and Ayapanin

P. K. BOSE and B. B. Sarkar, writing from the University College of Science, Calcutta, report preliminary observations on the hæmostatic action of two substances isolated from the leaves of *Eupatorium ayapana* Vent., a decoction of which has long been a popular remedy against various kinds of hæmorrhage in Hindu medicine. The substances are termed ayapanin, identical with 7-methoxycoumarin, and ayapin, identical with 6 : 7-methylenedioxycoumarin; in each case similar hæmostatic effects were found with the synthetic and natural compound; no effects on heart, respiration or blood pressure were observed. The coagulation time of rabbits' blood was diminished when traces of finely divided ayapanin or ayapin were added *in vitro*, when saturated solutions of the compounds in physiological saline were injected subcutaneously, and when the substances were given by mouth, the effect in the latter instance lasting approximately one hour. The closely related substances coumarin, 7-hydroxycoumarin and sodium *p*-methoxycinnamate had no effect on clotting time.

Hot-water Treatment of Bulbs

HOT-water treatment is now the standard method for dealing with Narcissus bulbs infected by eelworm, but although it has given a considerable measure of success, its efficiency has not reached the standard which was to be expected on theoretical grounds, or could be usually obtained with small-scale trials. The question has been under investigation during the past few years by Messrs. Staniland and Barber of Seale-Hayne Agricultural College, and the results of their inquiry have been issued by the Ministry of Agriculture as Bulletin 105, "The Efficiency of Baths used for the Hot-Water Treatment of Narcissus Bulbs" (H.M. Stationery Office, price 1*s*.). Unsatisfactory results could be traced to a number of different causes, but the factor which seems to have led most frequently to the survival of eelworm during treatment is the use of sacks to hold the bulbs, for penetration and circulation of the water within a sack is slow, and the majority of the bulbs fail to reach the requisite temperature under these conditions. Practical suggestions are given for improvements, such as the use of rigid containers in place of sacks and the introduction of a circulatory system where rectangular tanks are employed. Attention is also directed to the fact that inaccurate thermometers or incorrect steam pressures are frequently the cause of apparent inefficiency of the method. It is hoped that the practical recommendations provided in the bulletin will result in the hot-water treatment giving even greater satisfaction than it has in the past, for there is no doubt that such treatment has been the saving of the bulb industry.

Transfusion of Quartzite

DORIS L. REYNOLDS has described (*Min. Mag.*, 24, 367; 1936) in great detail the most convincing example which has yet been recorded of the transformation of quartzite into rocks that are indistinguishable from common igneous types. The hornblendite of three small composite intrusions in Colonsay is thickly sprinkled with blocks of white quartzite, most of which exhibit various stages of replacement by micropegmatite, syenite and appinite. Completely replaced xenoliths are represented by felspathic patches and schlieren. Finally, the process of transfusion gave rise to syntectic magma, of syenitic and appinitic composition, now represented by veins which emerge from metasomatized quartzite. By study of successive replacement zones and chemical analyses, it is found that differential migration into the quartzite of various magmatic constituents took place. The paper is followed by one in which A. Holmes describes the augite-rimmed xenoliths of transfused quartz which occur in many of the alkali basic and ultrabasic lavas of south-west Uganda (*Min. Mag.*, 24, 408; 1936). Transfusion begins with the development of intergranular channels of glass and continues until only isolated relics of quartz remain. Microchemical analyses (by F. Hecht) of three samples of glass from pure quartzite or vein-quartz show that the glass has the composition of silica-rich potassic obsidian. The constituents which migrated into the quartz were mainly those of alumina, potash and water. Comparison is made with the Colonsay phenomena, and in both papers references to many comparable but less well-authenticated examples are given.

Effect of a Magnetic Field on Adsorption

THE effect of a magnetic field on the rate of crystallization and some physical properties of substances is well-known. S. S. Bhatnagar, P. L. Kapur, and A. N. Kapur have recently reported the results of the effect of a magnetic field on the extent of adsorption (*Phil. Mag.*, (7), 23, 256; 1937) The systems studied were the adsorption of potassium permanganate, potassium dichromate, potassium ferrocyanide, and ferric chloride on sugar charcoal, and that of potassium permanganate and potassium ferrocyanide on barium sulphate. In the case of potassium permanganate, potassium dichromate, and potassium ferrocyanide, there was a small but definite increase in the adsorption by sugar charcoal in the magnetic field. With ferric chloride on sugar charcoal there was a decrease, whilst for adsorption of potassium permanganate and potassium ferrocyanide on barium sulphate there was no effect. The authors discuss the effects with sugar charcoal in the light of the view put forward by a number of workers, but particularly by Burrage, that active charcoal is covered with a film of active oxide which cannot be removed even by prolonged heating in a vacuum. The filtrate from the potassium permanganate experiments with charcoal was found to contain a suspension of manganese dioxide, the presence of which may be ascribed to the interaction of the permanganate with the active oxide. Similarly, chromic ions were found in the filtrate from the dichromate adsorptions. In the adsorption of ferric chloride it is probable that the active oxide forms iron carbonyl and is thus removed. Potassium ferrocyanide was found to be partly oxidized to the ferricyanide during the process of adsorption. These facts favour the existence of an active oxide of carbon, and a chemical theory of adsorption. The authors go on to show that the effect of a magnetic field on the adsorption which was found by experiment is in agreement with the rule put forward by them in 1929, that a reaction would be accelerated, retarded, or remain unaffected according as whether the sum of the molecular susceptibilities of the products is greater than, less than, or equal to the sum of the molecular susceptibilities of the initial substances.

Protein Films

IN *Science* of January 15, Drs. Irving Langmuir and V. J. Schaefer of Schenectady collaborate with Dr. Dorothy M. Wrinch of Oxford in a very interesting study of films of protein transferred to solids from water surfaces. In order to facilitate optical study of these films, they were deposited on a polished chromium-plated surface. The method of deposition was similar to that already worked out by Langmuir and Miss Blodgett, dipping the slide into water covered by a film; and two different types of protein film were obtained according to whether the slide was dipped into water already covered by a film, or dipped first into clean water, a film then put on, and the protein afterwards spread before withdrawing the plate. The two types of film probably differ in that one is applied the opposite way up to the other, and their outer layers are hydrophilic or slightly hydrophobic according to the manner in which they have been applied. Many successive layers can be built up, and any even number of layers of protein can be inserted between layers of stearate molecules, thus giving a close approach to possible structures for the surfaces of living cells. Studies of the penetration of liquids into these films have been commenced, and it appears that hydrocarbon liquids can easily penetrate into the holes (of molecular dimensions) left by the removal of the stearic acid molecules from a mixed barium stearate – stearic acid film. The water-retaining properties of these films depend on the orientation of the protein molecules.

Encounters between Pluto and the Neptunian System

MR. RAYMOND A. LYTTLETON, who has already contributed an interesting paper (*Mon. Not. Roy. Astro. Soc.*, 96, 566) on the origin of the solar system, prompted by Russell's severe criticism of the theory of Jeans, has a paper on this subject in the same journal (97, 2; Dec. 1936). The high eccentricity of Pluto, exceeding 0·25, implies that it may be nearer to the sun at times than Neptune, and for this reason encounters of Pluto have an important bearing on certain problems relating to the past history, as well as to the future, of the solar system. A rigid mathematical investigation leads to several interesting conclusions, amongst which the following may be noticed. Encounters between Pluto and the Neptunian system may have occurred in the past and may occur again. It is even possible that the orbit of Pluto may come within that of Saturn, and an encounter with Saturn could eject Pluto from the solar system, but as such an encounter is most improbable, the matter is of little interest. The action of Neptune, on the other hand, may cause great alterations in the orbit of Pluto, though it cannot eject it. The considerations in the paper lead to the conclusion that Pluto may originally have been a direct satellite of Neptune, and that an encounter which gave it an existence as an independent planet also reversed the general direction of motion of Triton. It is admitted, however, that this explanation of the retrograde motion of a true satellite is rather speculative.

The Gas Impregnated Cable

DURING the last few years, the development of cables suitable for high-tension currents has proceeded rapidly. In a paper read to the Institution of Electrical Engineers on March 10 by A. W. Arman, various types of these cables are described. The earliest type consisted of a copper core for carrying the current, separated by impregnated paper from a co-axial hollow copper cylinder which formed the return path. It was found that a limiting factor in this type of cable was due to the vacuous spaces (voids) which formed in the dielectric and caused ionization to occur at high electric pressures. The next type of cable was the oil-filled cable, in which low viscosity oil was introduced under moderate pressure from the hollow conductor and filled up the voids, thus avoiding ionization. It has been successfully applied to 132 kV. systems. The main drawbacks are that the cable and the associated apparatus are expensive. Another and more recent method of preventing the formation of voids in three-core cables is to use an impregnated dielectric of the usual type for the three cores and encase them in a thin flexible sheath. The cable is then drawn into a steel pipe, and the latter is filled with gas at high pressure. As the compound in the cable expands and contracts as the current it carries varies, the sheath 'breathes' to accommodate the varying volume and the high external pressure prevents the formation of voids. This type of cable is called the 'pressure cable'. The 'gas impregnated' cable, which the author describes, is intended to produce a 132 kV. cable based on sound principles. The insulation consists merely of high-pressure gas and dry paper. It is unaffected by heat cycles and so the dielectric can be run at a higher temperature than in other cables. Nitrogen at a pressure of 200 lb. per sq. in. was first employed but later on it was found that carbon dioxide gave a better performance.

Fuel Research

THE report of the Fuel Research Board* for the year ending March 31, 1935, differs from its predecessors in the emphasis given to problems arising from the preparation of coal for sale. This follows naturally on the changes taking place at British collieries, where increasing proportions of coal are obtained by mechanical methods, and are also subjected to various cleaning processes. Again, consumers become more reluctant to pay a premium for size. Apart from the open fire, there are few uses for large lump coal. It is the modern tendency to employ automatic mechanical methods of firing boilers, furnaces and producers, and for such uses coal must be small in size and uniformly graded. Formerly, small coal was often deliberately rejected by the use of forks for loading underground. To-day collieries are increasingly finding it necessary to break lump coal to supply the demand for small fuel, and this has brought into prominence many chemical and physical problems previously unknown. The best methods of breaking to preserve sizes and avoid the production of dust have been investigated. Coals broken and graded suitably at the colliery were found to suffer little further degradation in normal transport to the consumer.

The development of schemes for coal marketing has disclosed the need and opportunity to reduce the number of sizes of marketable coal. The Board is collaborating with the Midland Institute of Mining Engineers and the South and West Yorkshire Coal Owners in an attempt to do this. It was found, in this area, that no less than 106 different size grades of coal below 3 in. size were being marketed; and yet seventy per cent of the coal fell within 15 size grades. With slight adjustment of the size mesh, these 15 grades would cover ninety-five per cent of the tonnage. It is difficult to see any technical reason for marketing coal in so many sizes, and there must be advantage in selling to reduce the number.

Considerable attention has been given to the question of mixing or blending coal from different seams. It is often forgotten that the supply of good coking coal is limited. The problem of blending coals, which though unsuitable alone, give good coke when carbonized after blending with others, is receiving increasing attention.

The supply of active carbon suitable for respirators and gas masks is obviously a very important matter. Some materials on carbonization yield an active residue, but it is known that less active carbon can be activated by gasification with steam. The report records that it has been found possible at the Fuel Research Station to carbonize selected coals, of the durain type, and treat the coke with steam at a high temperature to obtain an active carbon nearly as good as the best obtainable and at a considerably lower cost. The importance of this observation needs no emphasis. The cost of active carbon is a limiting factor in processes for recovery of vapours.

Systematic work on the hydrogenation of coal and tar oils has been continued. Attempts to prepare first-class lubricants from coal tar oils have not been successful—possibly because the molecular structure of these hydrocarbons is unsuitable. It now appears that the most hopeful line is to synthesize hydrocarbons from carbon monoxide and hydrogen, and experiments in this direction have been initiated.

The report touches most aspects of national fuel problems and may be commended to those who seek a conspectus of the current position. H. J. H.

Twenty-fifth Anniversary of Laue's Diagrams

IT has been a pleasure to men of science in Great Britain to see the growing interest taken and progress made in science in India. The rapidly increasing list of original investigators, and the importance of many of their papers, contributed not only to their own institutions but also to learned societies in Great Britain, are a source of sincere gratification. Forty years ago (1896) I was present at the opening of the completed Indian Institute in Oxford, by the ex-Viceroy, Lord Dufferin, accompanied by Mr. Asquith (afterwards Prime Minister and Lord Oxford), who made a remarkable speech in welcoming our Indian co-subjects of the British Crown to partake of the best of our educational facilities. The fraternal lead then given has borne such wonderful fruit that India itself is now providing all that is needful, without any longer feeling the necessity of expatriating its sons to Europe for their higher education.

These facts are remarkably illustrated at the moment by the appearance of a special number of *Current Science*, a monthly journal devoted to science published at Bangalore, with the aid of thirty natives of India. This special number is devoted entirely to marking the twenty-fifth anniversary of the discovery by Laue of the diffraction of X-rays by crystals, and to the review of the years of intense research into crystal structure which have followed. It contains a dozen articles by the leaders in this work, the first being by Prof. Max von Laue himself, with his portrait as frontispiece. Succeeding articles are by Sir William and Prof. W. L. Bragg, Prof. P. P. Ewald, Prof. M. Siegbahn, Prof. A. Sommerfeld, Dr. L. Pauling, Prof. C. G. Darwin, Prof. H. Mark, Prof. J. A. Prins, Dr. S. K. Allison, Prof. H. A. Kramers, and Dr. S. Rama Swamy; an introduction is also contributed by Sir C. V. Raman. The mere fact that such a remarkable jubilee 'Festschrift', celebrating Laue's epoch-making discovery, should be organized by our Indian scientific brethren, speaks volumes for the advance of science in India.

There is every reason why I should feel specially warm towards this interesting brochure. For, twenty-five years ago (1912) I was the guest for a week of Prof. P. von Groth, the veteran crystallographer, at Munich almost immediately after the discovery made in the adjacent laboratory, and was shown the first negatives taken by Laue and Sommerfeld's assistants, Friedrich and Knipping, of copper sulphate and zinc blende. I was, indeed, by Dr. Laue's kindness, provided with duplicates of these and of the negatives of the apparatus used, and lantern slides from them were shown in a Friday evening discourse given by me at the Royal Institution shortly after my return to England. It was only in the preceding year, 1911, that my treatise on "Crystallography and Practical Crystal Measurement" was published by Messrs. Macmillan and Co. Ltd., representing the state of crystallography at the moment of Laue's discovery; and the twenty-five years of X-ray analyses of crystals which have followed, have confirmed and substantiated the contents of that work, which was expanded to two volumes in 1922, including a full account of X-ray work. No structure has been revealed by X-rays which does not conform to one or other of the 230 types of possible crystal structure clearly defined by the independently corroborating work of Schoenflies, Fedorow, and Barlow. The relative dimensions of the crystal unit cells, containing one or more molecules of the substance, which were given by me for the members of the several series of isomorphous substances which I had investigated in sufficient detail, were not only confirmed but also—and this was the greatest achievement of X-ray analysis—converted into absolute measure, in Ångstrom units.

Moreover, the generality of the law that the whole of the crystallographical and physical constants of the members of isomorphous series showed a regular progression with the atomic number of the interchangeable elements forming the series, was at this moment being somewhat criticized (but only as to the generality of its application), on account of an apparent important exception in the case of the haloid salts of the alkali metals. I had been careful to stipulate that the law only applied so long as the type of structure (one of the possible 230 types) remained rigorously the same throughout the whole series. X-ray analysis at once cleared up the mystery, for it indicated that there was a change of type between rubidium and cæsium chlorides; for while potassium and rubidium chlorides resemble sodium chloride in belonging to the face-centred cubic type of space-lattice, cæsium chloride belongs to the body-centred type, so that the law is totally inapplicable, the members of the series not being all strictly comparable with each other.

Many other instances of the assistance afforded by X-ray analysis to the clearing up of doubtful cases could be quoted. It should further be pointed out that in obtaining the results, which led to the law of progression, extreme refinement in angular and other fine measurement was essential, and the use of only the most perfect small crystals, grown with the greatest care free from either mechanical or thermal disturbance, such, in fact, that those crystal-angles which were of equal value with respect to the symmetry would not vary more than two minutes of arc. The so-called 'mosaic' crystals, which appear to give better reflection results in X-ray analysis, owing to the use of the rotating integrating method of using the X-ray spectrometer, are merely imperfect hastily grown crystals, which I would have ruthlessly rejected as being useless for the purpose in view.

It is thus obvious that it is the combination of the most refined of the older (pre-1912) crystallographic methods, with the newer X-ray analysis, that will give us the fullest knowledge of crystal phenomena and structure, one being complementary to the other, and the two together giving us the truth in full. The fascination of X-ray analysis has caused almost a cessation of crystal-angle and optical and other physical constants measurement, and one must hope that now so many structures have been unravelled by X-rays, of both inorganic and organic substances, more attention will be paid to goniometrical, optical, elastic, magnetic and electrical measurements with crystals. The purely structural X-ray work will then occupy its proper important position in the complete research.

In his personal article, Prof. von Laue throws a little further light on the circumstances in which in February 1912 his discovery was made. One evening in that month, P. P. Ewald went to him for advice as Privatdozent as to a difficulty which had arisen in preparing his (Ewald's) thesis for the Munich doctorate, on a subject which he had undertaken at the instance of Prof. Sommerfeld. During the discussion, the fact became prominent that a crystal is essentially a three-dimensioned lattice, and the question suddenly dawned in Laue's mind, as to what would happen if such a lattice were approached by a radiation of which the wave-length was short compared with the lattice-constant (unit cell dimension). The analogy of light waves and gratings suggested that diffraction must ensue. Remembering that Wien and Sommerfeld had only recently found Rontgen rays to possess a wave-length of the order 10^{-9}cm., and that the lattice constant must be somewhere about 10^{-8}cm., Laue came at once to the inspiring conclusion that the conditions for diffraction were highly favourable. Just at that moment entered W. Friedrich, Sommerfeld's assistant, and hearing the conclusion of the discussion, at once expressed a wish to put the matter to an immediate experimental test. Now Laue was obviously accepting Sommerfeld's view that the X-rays were a wave-motion, electromagnetic waves of excessively short wave-length, and not corpuscular, as was at that time supposed by Prof. W. H. (now Sir William) Bragg.

Friedrich obtained the help of a specially able experimental colleague, P. Knipping, and the apparatus was soon rigged up for passing a beam of X-rays through a crystal, and interposing a photographic plate in the path of any transmitted or diffracted rays. But unfortunately the crystal chosen, from being so easy to obtain well developed, was copper sulphate, which crystallises in the triclinic system of lowest symmetry. The effect on the photographic plate after development, although very promising, was confused, owing to the lack of symmetry. But on substituting a crystal of zinc blende, as advised by Prof. von Groth who lent the crystal, which is of cubic symmetry, the now well-known excellent pattern of cubically symmetrically arranged spots was obtained. After repeated confirmations and discussions of the meaning of the results, Prof. Sommerfeld was able to present the epoch-making paper of Laue, Friedrich and Knipping, on June 8, 1912, to the Munich Academy.

It would appear that the subsequent entrance of Sir William Bragg, and of his son W. L. Bragg, into the field was due to an attempt to discover whether Laue's effects were caused by the X-rays themselves (as corpuscular) or by electromagnetic wave-radiation associated with corpuscular rays. W. L. Bragg, then a student at Cambridge, was soon able to show that the zinc blende pattern of spots was due to the symmetry of the crystal, and not to the character of an X-ray spectrum; and he followed it up by determining the actual arrangement of the atoms in the still simpler cubic crystals of potassium and sodium chlorides. Sir William Bragg then found that the reflected X-rays, when analysed by an ionization spectrometer, consisted both of a general (continuous) spectrum and of rays of characteristic wave-lengths (Barkla's K and L rays), and that indeed Laue's explanation of the effect as a diffraction of electromagnetic waves must be accepted.

Moseley's brilliant measurement of the wave-lengths or frequencies of the characteristic X-radiations of the various elements immediately followed, and their relations were shown to offer a complete explanation of the Periodic Law of the elements; and the sequence number (atomic number) of the element suddenly developed a wonderful and unanticipated meaning, in expressing the positive charge on the nucleus of the atom, and the number of the surrounding planetary negative electrons. By a combination of the use of the Laue photographic method and the Bragg ionization spectrometer, together with the Debye powder method when good crystals are not available, and the rotating methods more lately introduced, all the important subsequent progress in unravelling the internal structure of crystals, not only of very simple substances but also of many complicated ones, including organic substances containing a large number of atoms in the molecule, has been achieved.

In their article Sir William and Prof. Bragg scarcely do justice to the really great progress which had been made in crystallography previous to 1912. They state that "at that time crystallography was so much a science apart, and played so little part in physics and chemistry, that the idea of a crystal pattern had never presented itself to the majority of scientists". If this were really the case it was the fault of workers in other scientific fields; for a small band of devoted crystallographers were insistently, in season and out of season, directing attention to the subject, and to its immense importance to physicists and chemists.

My own "Crystallography and Practical Crystal Measurement" set it forth clearly in the year 1911. The Laue discovery came at the most psychologically appropriate moment, to clinch the facts, to arouse universal interest in the subject, to reveal the 230 types of crystal structure already specified and defined by the genius of Barlow in Great Britain and simultaneously and independently by Schoenflies and Fedorow on the Continent, as real entities and not merely the natural deductions from all the accumulated experimental work on crystals, and to add that to crystallographic knowledge which rendered it assured and incontrovertible.

Sufficient will have been said to indicate the value of this Laue special number of *Current science*, and it is with all sincerity that we congratulate our Indian scientific colleagues in so admirable a production. In the preface, it is foreshadowed that other special numbers are being prepared, on canal rays, genetics, and on animal development, and among the articles in the first mentioned we are promised contributions by Sir J. J. Thomson, Dr. F. W. Aston, and Dr. J. D. Cockcroft. We shall look forward to these further special numbers with all the greater interest, from the pleasure which the perusal of the present issue commemorating the initiation of Laue diagrams has afforded us. A. E. H. TUTTON.

The Chemical Research Institute, Warsaw

THE Chemical Research Institute of Warsaw (Chemiczny Instytut Badawczy w Warszawie) was founded by Prof. Ignacy Mościcki, who is now President of Poland. Firm in his conviction that the independence of Poland would be restored and that the country would then need the services of such an institute, Prof. Mościcki took the first steps to realize this aim during the Great War, in 1916. He founded the Metan Company in Lwów, the object of which was to carry out chemical research for industry. The shareholders of the Metan Company voluntarily resigned from their material interests in this organization in 1922, and transformed it into the Chemical Research Institute Association, which pays out no dividends, in accordance with its by-laws, and expends all revenue and earnings on the prosecution of new research work. Having thus arisen without the help of the Government or of industry, the Institute was in 1925 transferred to Warsaw, where it has since 1927 occupied its own commodious, modern building, erected thanks to the donations of Poles, both at home and abroad. The building was officially declared open in 1928 by Prof. Mościcki, who had in the meantime been elected President of the Republic. The Institute contains a Department of Inorganic Industry, a Coal Research Department, an Analytical Department, an Alcohol Research Department, a Department of Rubber Synthesis, etc.

The personnel of the Institute at present numbers 161. The director is Prof. Kazimierz Kling, one of the co-founders of the Metan Company. The other members of the executive board are: Prof. Wojciech Świętosławski (at present Minister of Education), Prof. Jan Czochralski, Prof. Wacław Leśniański, Mr. Jerzy Pfanhauser, Miss Halina Starczewska and Mr. Zdzisław Zaleski. The chairman of the Board of Curators is Mr. Eugeniusz Kwiatkowski, the present vice-premier and Minister of Finance.

The Institute is engaged in tracing out the lines of the technical progress of the chemical industry of Poland, with special reference to the possibilities of extending the use of and improving Polish raw materials on one hand and of substituting imported raw materials by home-produced ones on the other.

The research work conducted by the Institute is chiefly concerned with petroleum, natural gas, sulphuric acid, aluminium, the analysis and standardization of coal, metallurgical coke and rubber. The twentieth anniversary of the foundation of the Institute was celebrated in the Warsaw Polytechnic on December 9, the president of the Republic of Poland being present.

University Events

BIRMINGHAM.—At the recent annual meeting of the Court of Governors, the pro-chancellor, Mr. Walter Barrow, announced a bequest of £5,000 by the late Lady Scott-Moncrieff, who was one of the original students of Mason College. The late Prof. R. F. C. Leith, emeritus professor of pathology, bequeathed a sum of £15,000 to the Department of Pathology and £15,000 to be used for scholarships to promote the study of pathology and bacteriology. The late emeritus Prof. Lewis and Sir John Robertson also bequeathed their libraries to the new Medical School. An anonymous donor has given £2,000 to enable an investigation to be carried out under the personal direction of Prof. W. N. Haworth with the view of producing an improved form of insulin for use in the treatment of diabetes, and two research fellows are already at work on the subject.

Part of the new Hills Chemistry Block is already in occupation, and it is expected that the whole will be ready for use in the summer term. A further sum of £6,050 has been received in donations towards the equipment of the building.

The fund for the Medical School, which received £50,000 as its share of the proceeds of the Hospitals Centre general appeal, has received further donations to the amount of £12,000, including £10,000 from Sir Charles Hyde for a Chamberlain Memorial Museum, £500 from the Dean of the Faculty of Medicine (Dr. Stanley Barnes) and £101 from the Guild of Graduates. It is hoped that the school will be ready for occupation in 1938, but a considerable increase in available funds is required.

The Department of Industrial Hygiene and Medicine has received donations to the amount of nearly £1,670 from various industrial firms and has been actively engaged, evidently meeting a widely felt want. Arrangements have been completed for the establishment, under the joint auspices of the Birmingham United Hospital and the University, of consultation centres in industrial hygiene and medicine at the Queen's and General Hospitals.

As a consequence of the death of Prof. J. S. Haldane, the Mining Research Laboratory is being transferred to the Imperial College of Science and Technology, London, on April 1.

CAMBRIDGE.—R. G. Hawtrey, formerly of Trinity College, has been appointed to the Alfred Marshall lectureship for the year 1937–38.

The following grants from the Worts Fund have been made: £25 to J. K. S. St. Joseph, towards the expenses of a visit to certain Continental museums for the purpose of studying the palæontological collections there; £40 to W. V. Lewis, towards the expenses of an expedition to East Iceland to study the geography and natural history of this region; £50 to J. W. Wright, towards the expenses of an expedition to Ellesmere Land to study the geology and the birds of that country; £10 to Miss W. Lamb, towards the expenses of a visit to Turkey for archæological purposes; £40 to J. R. B. Stewart, towards the expenses of a visit to Cyprus for archæological purposes; £40 to Miss M. Fearnsides, towards the expenses of a journey across Scandinavia for the purpose of studying the ecology of certain areas; £40 to H. E. Hinton, towards the expenses of a journey to Lake Titicaca, Peru, to study the aquatic insects there; £12 to Miss E. M. McIndoe, towards the expenses of a visit to the Stazione Zoologica at Naples for the purpose of studying the acclimatization of animals to temperature; £40 to J. L. Mason, towards the expenses of a visit to Algeria to study the fauna of the hot springs there.

The General Board recommends that the following additional teaching offices be established on October 1: a university demonstratorship in the Department of Geology; a part-time University lectureship in the faculty of Mathematics; two University lectureships in the Department of Chemistry (temporarily replacing two demonstratorships); a university lectureship in the Department of Physics, replacing an assistant directorship of research; two University demonstratorships in the Department of Botany (replacing a University lectureship); a university lectureship in the Department of Parasitology. The General Board recommends that a readership in plant morphology be established for one tenure only, and that it be authorized to appoint Dr. H. H. Thomas to this post from October 1.

OXFORD.—H. M. Sinclair, University College, has been elected to the Radcliffe travelling fellowship in medicine for 1937.

H. S. Brodribb, University College, and Miss J. Wright, Somerville College, have been granted the degree of M.D.

SHEFFIELD.—J. A. Wragg has been appointed assistant to Dr. W. A. Timperley, research fellow in the Department of Physiology.

R. Ibbotson has resigned his post of demonstrator in non-ferrous metallurgy.

Science News a Century Ago

Karl Himly (1772–1837)

MARCH 22 marks the centenary of the death of the eminent German eye specialist Karl Gustav Himly, to whom scientific nomenclature is indebted for the words 'ophthalmology' and 'mydriatics'. He was born on April 30, 1772, at Brunswick, where he attended the medico-chirurgical college from 1790 until 1792, and then continued his medical education at Göttingen under Richter. In 1795 he was appointed professor at the College at Brunswick, where he remained until 1801, when he was elected to the chair of medicine at Jena. Two years later he was made director of the Academy Hospital at Göttingen, where he inaugurated a course of theoretical and practical instruction in ophthalmology and gained a well-merited reputation both as lecturer and as operator, so that in 1816 he was made an honorary professor of the University of Pisa.

Himly's importance in the history of ophthalmology lies not only in his systematic use of mydriatics, but also in his having founded the first journal devoted to his speciality. In conjunction with Johann A. Schmidt, between 1802 and 1806, he brought out three volumes of a journal entitled *Ophthalmologische Bibliothek*, which was continued by himself alone under the name of *Bibliothek für Ophthalmologie* in the period 1816–19 during which two volumes appeared. He was also the author of a text-book on practical therapeutics (1807), and from 1809 until 1814 was co-editor with Hufeland of the *Journal für praktische Heilkunde*. His posthumous work on diseases and malformations of the human eye and their treatment, with additions by his son, E. A. W. Himly, appeared in 1843.

The Surface of the North American Continent

ON March 22, 1837, the Geological Society listened to a paper by Mr. Roy entitled "On the supposed ancient state of the North American continent, especially on the extent of an inland sea, by which a great portion of its surface is conjectured to have been covered". The author, who had been employed on extensive surveys in the Lake District of North America, found on drawing sections for professional purposes that the country everywhere exhibited successive ridges which encircled the lakes; and upon comparing sections to the north of Lake Ontario with others to the south, that the ridges exactly corresponded in elevation. The highest of these ridges is 996 ft. above sea-level or 762 ft. above that of Lake Ontario. Connecting this elevation with the physical features of the valleys of the Mississippi and Missouri, Mr. Roy supposed that the whole area from the Rocky Mountains to just below Quebec down to the Gulf of Mexico formed one vast inland sea 960,000 square miles in area.

British Railways

IN a notice in the *Athenæum* of March 25, 1837, of F. Whishaw's "Analysis of Railways", the following quotation from the book was given: "The number of proposed Railways, including Diversions, Extensions and Branches in England and Wales, for which plans have been lodged in the Private Bill Office in the present Session, is seventy-five, of which only forty-eight are under the consideration of Parliament; these amount in length to 1233 miles, and are estimated at the sum of £19,352,726 or £15,625 per mile. The whole length of tunnelling is twenty-five miles and the number of bridges, exclusive of viaducts and culverts, 2,825 or nearly two and a third per mile. The weight of iron required for the rails is 193,500 [illegible]d of stone for the blocks 2,670,000 tons. The [illegible]of the land is upwards of 1,500 acres; and of [illegible] for the chairs 130 acres. These Railways, if [illegible]rried into execution, would employ at least 5,000 men and 1,500 horses for three years for the earthworks alone."

Dumont D'Urville's Voyage in the *Astrolabe*

IN the *Nautical Magazine* of 1837, it is stated: "The king of the French has by a decision of the 26th March approved of a proposal for a new voyage round the world, the conducting of which is to be confided to M. Dumont D'Urville. Two vessels will be employed in this expedition; the *Astrolabe*, commanded by Captain D'Urville and the *Zelee* by Captain Jacquinot. Leaving Toulon about the middle of September, they will proceed due south to the polar sea to pursue Weddel's track, who it will be remembered reached the latitude of 74° 15′. The vessels will penetrate as far south as possible and return to the Magellan Straits. In the spring of 1838 they will leave Valparaiso for the Polynesian Archipelago, and in June will be at Vavoo, where M. D'Urville will finish the work left undone by the *Astrolabe* in 1827. They would then visit in turn Banks Island, the Solomon Islands, the Dutch Settlements in Aroo and Key Islands, Amboina, New Holland, Tasmania, New Zealand, Borneo, Sumatra and return home by the Cape. Commenting on the announcement the *Nautical Magazine* said: "We look on this as a most interesting expedition and one that will yield important results. We cannot, however, but regret to see so extensive and important an island as New Guinea, left year after year, in its original neglected condition and with but little addition to its coasts since the time of Dampier."

Jean Sebastian Cesar Dumont D'Urville, who was born on May 23, 1790, had circumnavigated the globe under Captain Duperrey (1756–1865) in the *Coquille* in 1822–25. Promoted to captain, in this ship, renamed the *Astrolabe*, he left Toulon in April 1826 and proceeded to the Pacific, returning in March 1829. His third voyage began on September 7, 1837. After his return home he began the publication of the results of his voyage and had completed the second volume, when on May 8, 1842, with his wife and son, he was killed in a railway accident on the line from Paris to Versailles.

Royal Dublin Society, February 23

J. BREEN, G. M. KENNEDY, J. KEANE and T. J. NOLAN: Chemical constituents of lichens found in Ireland—*Lecanora sordida*. *Lecanora sordida* was found to contain atranorin, chloratanorin, roccellic acid, and, in minor amount, a product similar to thiophanic acid and containing fourteen per cent chlorine. Roccellic acid, $C_{17}H_{32}O_4$, was established by synthesis as α methyl α' dodecyl succinic acid.

J. W. PARKES, W. S. HAMILTON, E. J. SHEEHY, P. A. MURPHY, G. SHERRARD, M. J. GORMAN, D. MELLON and T. O'CONNELL: A symposium on fertilizers.

Paris

Academy of Sciences, February 15 (*C.R.*, 204, 457–532).

JACQUES HADAMARD: Observations on notes by Destouches and by Appert. These authors have arrived independently at the same results. The present note raises a question of nomenclature.

ARMAND DE GRAMONT and DANIEL BERETZKI: The determination of the surface of a piezo-electric plate as a function of its frequency.

MARCEL LINSMAN: Real left arcs and curves of the fourth order.

L. KANTOROVITCH and E. LIVENSON: Some theorems concerning the theory of projective ensembles.

JEAN DELSARTE: A generalization of Taylor's formula.

LAURENCE C. YOUNG: A generalization of the idea of variation of the *p*th power in the sense of Wiener, and on the convergence of Fourier's series.

JOSEPH BARTA: The fundamental vibration of a membrane.

F. GRUSON: The representation of the ground in aerodynamic trials of vehicles.

SVETOPOLK PIVKO: A rational definition of the quality of supporting helices.

LÉOPOLD ESCANDE and GEORGES SABATHE: Remarks on the calibration of hydrometric velocity meters by displacement in a confined medium. Study of the effects of the transversal dimensions of the channel in which the instrument is moved.

DIMITRY PANOFF and PAUL RIZ: An apparatus for recording the deformations and vibrations of an aerial screw during flight.

MLLE. PAULETTE FÉVRIER: The uncertainty relations of Heisenberg and logic.

JEAN ROUBAUD-VALETTE: The relations between the polarisation of a photon and the spins of constituent corpuscles.

J. J. PLACINTEANU: The properties of the electronic photon.

R. BERNARD: The influence of pressure on the function of stimulation of bands of the ionized nitrogen molecule.

MARCUS BRUTZCUS: The intrinsic values of the linkages (C—O) and (C—H) in hydrocarbons.

RENÉ DELAPLACE: The vapour pressure of saturated and unsaturated hydrocarbons at low temperatures. The method is based on previous work on the conductivity of gases under low pressures. Vapour pressures of nine gases are given over a temperature range of from − 120° C. to − 196° C.

PIERRE VALLET: A tetrahydrate of zinc sulphate.

MARCEL PATRY: The action of alcohol on aqueous solutions of potassium tellurate.

JEAN MARIE MERCIER: A double bromide of iron and ammonium. The double bromide $NH_4FeBr_3.6H_2O$ was isolated: it gave a characteristic X-ray diagram, differing from those of its constituents.

PANOS GRAMMATICAKIS: The action of mixed organo-magnesium compounds on the phenylhydrazones of ketones. A new mode of action of mixed organo-magnesium compounds.

MAURICE MARIE JANOT and THÉODOR TOMESCO: The hydrogenation of some glucosides by active nickel. Details of the hydrogenation in the presence of Raney nickel of eleven glucosides.

GEORGES DARZENS: A new contribution to the synthesis of glycerol. The starting point is ethoxyacetic ester, and the series of reactions proposed give good yields throughout.

MAXENCE MEYER: Two new ethylenic aldehydes.

RENÉ PERRIN: Non-metallic meteorites can give no information on the nature of stony rocks.

MLLE. FERNANDE FLOUS: The evolutive characters of the cone of the Abietineæ.

MME. H. HOCQUETTE: Considerations on the Anabœniolum of the guinea pig and the rabbit.

MARIUS CHADEFAUD: Intranuclear cyclosis in the basidium of certain Hymenomycetes.

ALBERT BERTHELOT and MLLE. GERMAINE AMOUREUX: The sensibility of some aseptic seedlings to some carcinogenic substances.

CONSTANTIN DAWYDOFF: The supposed metamerization of the larvæ of the Hexacorallæ.

CHARLES LAPICQUE: The coloration of retinal images and chromatism in general.

RENÉ SALGUES: The elements of normal phosphatæmia in amphibians and reptiles.

ALEXANDRE GOURÉVITCH: The distribution of flavin in the tissues of mammals, in relation with their residual respiration in the presence of cyanides.

MME. VÉRA DANTCHAKOFF: The effects produced by a dose of 0·05 mgm. of testerone on the histogenesis of the female in the guinea pig.

Moscow

Academy of Sciences (*C.R.*, 4, No. 8; 1936).

S. SOBOLEV: A direct method for the solution of polyharmonic equations.

P. L. KALANTAROV: Fundamental values in the study of electromagnetic phenomena.

I. A. KHVOSTIKOV and A. N. SEVČENKO: Application of the polarimetric method to the study of the upper layers of the atmosphere.

A. E. FAVORSKIJ and P. A. TIKHOMOLOV: The problem of mutual influence of radicals on their migration. (2) Dehydration of tertiary phenylhexylcarbinol.

F. M. ŠEMIAKIN and A. I. LAZAREVA: Investigation of the reaction in which magnesium hydroxide is produced in gelatine.

A. V. FROST, D. M. RUDKOVSKIJ and E. K. SEREBRJAKOVA: Reversible catalytic conversion of *n*-butylenes into isobutylene.

B. L. ISAČENKO and N. N. MALČEVSKAJA: Biogenic spontaneous heating of peat.

I. A. GOLJANIZKIJ and K. A. BRJUŠKOVA: Vitamin C (*l*-ascorbic acid) in tea.

V. GLIVENKO: Mendelian algebra.

L. V. POLEŽAEV: Determination of initial stages in the development of extremities in amphibians.

Sydney

Royal Society of New South Wales, October 7.

M. D. GARRETTY: Some notes on the physiography of the Lake George region, with special reference to the origin of Lake George. Following the work of Taylor in 1907, Lake George, New South Wales, has long been held to have had its origin in recent normal faulting along its western shore. The streams to the east were betrunked, deprived by the fault scarp of their connexion with the Murrumbidgee System, and impounded to form the lake. In the present paper the pertinent physiography of the region is described, and the tectonic origin of the western escarpment questioned. An alternative explanation for the lake based on normal stream development and gentle warping is submitted.

November 4.

D. P. MELLOR and H. MULHALL: The el[illegible] potential of thin films of zinc on platinum. [illegible] attempt is made to determine the minimum thick[illegible] of zinc when plated on platinum to produce the sam[illegible] electrode potential as the massive metal. Experimental results indicate that it is impracticable to answer this question definitely.

R. LEMBERG and R. A. WYNDHAM: Some observations on the occurrence of bile pigment hæmochromogens in Nature and on their formation from hæmatin and hæmoglobin. Observations are dealt with on the formation of bile pigment hæmochromogens by autoxidation of hæmatin in presence of nitrogenous compounds and reducing substances, on their occurrence in Nature, and on the removal of iron from them. Verdohæmochromogens are found in catalase preparations from horse liver, in preparations of cytochrome *c* from yeast and (in traces) in extracts from blood of horse and pig. Verdohæmochromogens have to be considered as intermediate products of physiological bile pigment formation. Cytochrome a_3 is probably a biliviolin hæmochromogen.

ALMA G. CULEY and GERMAINE A. JOPLIN: Evidence of magmatic stoping in a dyke at Hartley, N.S.W. Field evidence is based on the facts (1) that the dolerite of the dyke follows prominent joint planes in the granite which it intrudes, (2) that inclusions of granite occur in the dolerite, and (3) that a small tongue or vein of dolerite surrounds a block of granite which is incompletely rifted off. This is probably the only recorded example of stoping in a small dyke. It is of interest, as emplacement of small intrusions is usually attributed to the lateral displacement of wall-rock.

A. Bolliger: Chemistry of Jaffe's reaction for creatinine. Jaffe's reaction, that is, the interaction of creatinine and picric acid in an alkaline medium, was studied. If this reaction is executed in alcohol, an orange-red crystalline compound can be obtained which consists of one molecule of creatinine, one of picric acid, and two of sodium. This substance may be responsible for the red colour obtained in Jaffe's reaction. The chemical constitution of this compound has been considered to be that of an organic molecular complex between sodium picrate and 'sodium creatinine'. On treatment with acid it furnishes a red isomer of creatinine picrate.

E. H. Booth: Some observations of zonal discordance in diurnal magnetic variations. Sets of readings have been (and are being) taken at the station "Hills and Dales", Mittagong, a district where the magnetic variations from point to point are small, for comparison with concurrent readings at the magnetic station of the Victorian Government at Toolangi. "Hills and Dales" is on the side of the magnetic mass of the "Gib", a syenite hill rising 800 feet above the surrounding country; so that it is both on a magnetized body and on a prominence. The results, after full correction, show that though there is generally fair co-ordination with Toolangi readings, the "Hills and Dales" readings are often swinging in a direction opposite to those of the Victorian station, and sometimes show magnetic fluctuations twice as great as those occurring at the same time at Toolangi even when atmospheric conditions are not abnormal. The conclusion is drawn that it is not safe to accept the variations at an established magnetic station to apply as corrections to a survey over magnetic prominences.

M. D. Garretty: Geological notes on the country between the Yass and Shoalhaven Rivers. The regional geology of about 1,600 square miles of country on the southern tablelands of New South Wales is briefly described. Probable representatives of the Upper Ordovician, Lower and Upper Silurian, Middle and Upper Devonian, Kamilaroi and Tertiary systems occur. Granites of epi-Silurian and epi-Devonian age cover considerable areas, and associated with them e examples of differentiated and hybrid rocks. T ral structure of the region is discussed.

Vienna

of Sciences, December 3.

d A. Hofmann: Substitution of
y (LiAl) in magnesium silicates.
: Local current theory of metal
tal potentials in oxidizing solutions.

Leonore Brecher: Coloration of the chrysalides of the cabbage white butterfly, *Pieris brassicæ* L., and of the vanessæ, *Vanessa io* L. and *V. urticæ* L. The effect of severing various nerves on the adaptation of the colour of the chrysalis to its surroundings is studied.

Martha Geiringer: Adrenalin as a synergist of thyroxin in the metamorphosis of toads (*Bufo vulgaris* Laur.).

Josef Glaser: Innervation of one or two legs grafted on *Dixippus morosus* Br. and Redt.

December 10.

Erwin Kamptner: Coccolites of the south-west coast of Istria.

F. Bukatsch: Influence of salts on the production of light by bacteria. Addition of salts increases the production of light, not by increasing the number of cells, but by increasing the light production of the individual cell.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, March 22

Victoria Institute, at 4.30.—Rev. T. E. R. Phillips: "Some Recent Views of the Universe and their Reactions on present-day Thought".

Engineers' Study Group, at 7.30—(at 23, Grosvenor Place, S.W.1).—Prof. R. A. Fisher, F.R.S.: "Family Allowances".*

Tuesday, March 23

House of Industry League, at 8.15—(Essex Hall, Essex Street, Strand, W.C.1).—Dr. V. Cofman: 'The Scientist's Task in the New Order".*

Wednesday, March 24

Institution of Chemical Engineers, at 6—(at the Chemical Society, Burlington House, W.1).—Dr. D. Hunter: "Prevention of Disease in Industry".

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Scientific Officers (radio and line communication), Junior Scientific Officers (radio and line communication) and Assistants (Grades II and III—physics or electrical engineering) at the Bawdsey Research Station, Bawdsey Manor, Woodbridge, Suffolk—The Superintendent, Bawdsey Research Station, Bawdsey Manor, Woodbridge, Suffolk (March 22).

Junior Assistant Entomologist (sugar beet pests) in the School of Agriculture, Cambridge—The Secretary (March 30).

Principal of the Huddersfield Technical College—The Director of Education, Education Offices, Peel Street, Huddersfield (March 31).

Lecturer in Mathematics in the Sir John Cass Technical Institute, Jewry Street, Aldgate, E C.3—The Principal (April 3).

Head of the Mechanical Engineering Department in the Rutherford Technical College—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne (April 7).

Lecturer in Charge of the Department of Botany in University College, Leicester—The Registrar (April 10)

Principal and Headmaster of the Gravesend Technical Institute and Junior Technical School—W. A. Clench, Bank Chambers, Windmill Street, Gravesend (April 10).

Lecturer in Geology in the University of Birmingham—The Secretary (April 10).

Curator of the Nottingham Natural History Museum—The Town Clerk, The Guildhall, Nottingham (April 12).

Assistant Keepers of Zoology and Mineralogy in the British Museum (National History), S.W.7—The Secretary (May 1).

Assistant Chemist for the Colne Valley Water Company—The Chief Engineer, Colne Valley Water Co., Aldenham Road, Watford, Herts

Science, Industry and Society

ALTHOUGH the recent annual report of the Department of Scientific and Industrial Research, an article on which appears elsewhere in this issue, contains much evidence of the increasing readiness of industry in Great Britain to make use of scientific method and scientific knowledge, particularly in the progress of the Research Association movement, the Advisory Council does not regard the position of the Research Associations as a whole as satisfactory, and points out that adequate advantage is not yet being taken of the grant offered. This warning has since been reiterated from the industrial side in respect of the woollen industry by Mr. D. R. H. Wilkins, a leading Huddersfield worsted manufacturer, in proposing a vote of thanks to Dr. J. B. Speakman for a lecture to the Huddersfield Textile Society on "The Chemist and the Mill" on February 22. Mr. Wilkins referred strongly to the short-sightedness of those textile firms which justified reluctance to finance research by arguing either that they were doing well enough without it or that they are not doing well enough to afford it.

The woollen industry is one of the two specially mentioned by the Advisory Council as having failed to provide the initial subscription to their Research Associations to qualify for the substantial block grant offered by the Department. The reluctance of this industry to finance research on an adequate scale is the more surprising in view of the admirable work that is already being carried out by its Research Association at Torridon with limited resources, and of the important fundamental discoveries on the chemical and physical structure of wool which have been made at the neighbouring University of Leeds in recent years. Such reluctance, however, gives further point to the emphasis which the Advisory Council lays on organizing the conduct of research so as to promote contact with industry.

From the point of view of industry, the report urges, research is only a means to an end—the application of scientific knowledge to all the stages of production, and the development of new processes. The application and development of scientific ideas in industry depend upon a complete understanding of the way in which industry can make use of science and scientific method, and this can only be achieved if the problem of co-operation is studied by the man of science as well as by the industrialist. The differences of experience, training and outlook between men of scientific education and many others engaged in productive industry are not always considered by those who are anxious to secure the potential benefits which science, wisely used, can bring to the community. The scientific worker has to meet the industrialist half way, and an important task of the Department of Scientific and Industrial Research is to assist the organization of such contact.

This question of co-operation, in one or other of its aspects, is probably the most important confronting industry and science to-day. It is not merely a matter of promoting contact between industry and science in such a way as to stimulate research in industries where it is at present comparatively neglected. The problem of promoting the application of science varies from industry to industry, partly by reason of the nature of the industry, partly by reason of its traditions and of the extent to which it has engaged the services of men of scientific training in its direction and its productive effort. The first step is, however, that of getting the industrialist to state his problems to the man of science, and to determine the order of priority, in terms of their economic importance, of the objectives of particular proposals for research.

The contribution which science can make to the solution of industrial problems depends on persevering effort on the part of industry and close co-operation between the industry and science. In this sphere, the staff of a research association can often make an invaluable contribution through their knowledge alike of the day-to-day problems of the industry and of science.

The statement of the problems concerned is important if the best method of attack is to be selected, because for industrial purposes to-day that may involve consideration not merely in terms of a particular science but also of a combination of sciences. Moreover, it may even involve consideration and attack from the point of view of several industries, if the fullest resources are to be utilized and the best results obtained. This, as the Advisory Council points out, is probably the most significant development in the industrial outlook in Great Britain in recent years.

The last five years have witnessed the fruition of the policy adopted by several large industrial undertakings of setting well-balanced teams of research workers including chemists, physicists, engineers, biologists or entomologists, and others to solve a particular problem or to develop a new product. To this method of attack are due the steady improvement in the efficiency of electric lamps, the position Great Britain has won in high-definition television, the commercial development of the conversion of coal into oil by hydrogenation, the growth of the plastics industry, etc. Great Britain has never been lacking in men of genius whose inventive capacity can give birth to the ideas which bring about industrial advances. What is new in the country is the way in which industry has taken up these new ideas, and brought them to the stage of industrial development by team work in which all the departments comprising a great business have worked side by side in the practical attainment of an objective.

For economic reasons, as well as because of the high degree of specialization which the advance of knowledge has made inevitable in scientific fields, the future no longer lies with industries that are content to make advances at the call of the brilliant investigator. Co-operation, team work and an extensive organization are essential for success. Further, the exploration of the borderland of different sciences which is facilitated and stimulated by such team work has proved, as so often happens in the history of science, provocative of new ideas and fundamental advances in knowledge. For this reason we need not fear that team work in research, if wisely organized and directed, need stifle individuality or cramp initiative or creative thought, as has been suggested in some quarters. Such dangers undoubtedly exist, but can easily be avoided by prudent management. Moreover, there is yet a third aspect of co-operation to which attention is directed, not merely by the report of the Department of Scientific and Industrial Research, but also by the recent appeal on behalf of the University of Oxford.

Among the examples of co-operative research to which the Advisory Council directs particular attention are the developments in building research and the formation of consultative groups in food investigation. The new Fire Testing Station which has been opened at Elstree represents the outcome of co-operation between the Building Research Station and the Fire Offices' Committee and indirectly the British Standards Institution, while similarly the Heating Laboratory which has been erected at the Building Research Station represents the outcome of substantial contributions from industry through the Institution of Heating and Ventilating Engineers. Again, the consultative groups which are being established by the Food Investigation Board are intended to assist in establishing a community of interest in the increase of scientific and technical knowledge through the whole range of industries concerned, whether production, transport, storage, marketing and retail distribution. The first of these groups has been established for the shipping industry and has proved highly successful, greatly facilitating discussions between the staff of the Department and representatives of the shipping companies on the many problems connected with the carriage of foodstuffs overseas and also arrangements for full-scale trials of modifications in existing practice.

It would be easy, however, to multiply examples of the way in which co-ordination of the research activities of different industries is required in the attack on problems of common interest, or of the way in which only by some measures of co-operative research between different industries or Departments of State can effective attack be made on problems of general national welfare and interest. What is, however, now emerging is the desirability of co-ordi n even wider field if the l ped from available resource

This factor a pertinence in this connexion to the r appeal on behalf of the University of Oxford for £500,000 for each of two research funds. Advances in scientific knowledge make ever more onerous the task of schools of science, medicine and social studies in keeping abreast of the needs of an age of rapid material and technical development, and in making adequate provision for advanced studies and post-graduate research. Moreover, the very advances in natural sciences, with the concomitant calls for funds for erecting new laboratories or extending existing ones, equipping and staffing them, and for improving the facilities for research in the various science departments including the provision of research posts, only strengthen the claims for further funds for the better organization and extension of research in the humane subjects, particularly provision for the study of human society and allied subjects such as anthropology.

What is clear is that we have reached a stage when it is imperative to take stock of the nation's resources and facilities for research, both academic and industrial. To neglect or starve research is to invite national peril, but the danger of unbalanced development in certain fields while others remain scarcely explored is too great to be ignored. Some means of securing a better distribution of the national effort in research is indeed long overdue, and such distribution must take due account of all research activities and facilities, whether by the Departments of State, at the universities or within industry. To such a national stocktaking the Department of Scientific and Industrial Research might well make a decisive and indispensable contribution. Few organizations are in a better position to encourage the prosecution within industry itself of intensive research in the applied and physical sciences, with all the important reactions which such research continually has on the technique and outlook of the underlying sciences themselves. The relations between academic and industrial research in the physical sciences at the present time, the extent to which progress depends on team work, independent of whether the investigation is prosecuted within the university or within industry, the inspiration and assistance which academic and industrial research in these fields are continually bringing to one another, give fundamental research in the physical sciences special claims upon the support of industry, apart from the rapidity with which discoveries in this field are applied to industrial purposes. If the main burden of research in such fields were accepted by industrial resources, it should be possible to redistribute research facilities at the universities so as to endow much more liberally that research in the social sciences which is so urgently needed if we are to attain an understanding of the problems of society, its organization and adaptation to the forces playing upon it to-day, whether within industry or outside it. Without such understanding there is dire peril that the riches with which scientific knowledge could endow us even now may never be enjoyed.

Urgent as is this problem, it is not one to be solved in a few months or perhaps even a few years. A wide vision and a generous spirit are demanded of all who seek to co-ordinate research resources and endowments in any such way, and if we are to attain to wise direction of research it will come first through the bringing together of many authorities concerned, in much the same way as the Food Investigation Board has brought together the scattered interests concerned in its problems in the consultative groups to which we have referred. To restrain research in a narrow or partisan spirit is to endanger its finest quality and inspiration. Neither to natural science nor to the science of civilization can money be wisely grudged, and the distribution between the two can only be determined safely by minds inspired by the same vision of what may be achieved by skilled workers, governed only by the truth that makes them free, and in their turn the guardians of the intellectual integrity and freedom that have prompted famous donations to learning in the past.

No degree of co-operation, no excellence of team work will avail us if such direction does aught to impair the power of the university to promote and maintain true liberty of thought, which to-day is so seriously threatened in many quarters. It is only when, in that sense, the university not merely inspires the progress of civilization but also defends it, that we can expect free play for the creative thought upon which progress everywhere depends, alike in the study of the urgent practical problems of government and social life, human and international relations and in the fundamental problems continually brought before the scientific worker by industry.

Mme. Curie's Swan Song

Radioactivité
Par Madame Pierre Curie. Pp. iii +564 +26 plates. (Paris: Hermann et Cie., 1935.) 150 francs.

THE fundamental new property of radioactivity, discovered by M. Henri Becquerel in 1896 in the course of a re-examination of the fluorescence of uranium salts, a subject in which both his father and his grandfather before him had been pioneers, was in itself a remarkable example of scientific genius running in families. It was followed two years later by the discovery of radium and other new naturally radioactive elements, a million-fold more active than uranium, by Mme. Curie and her husband, which has made her one of the most famous women of the age, if not of all time. She died in July 1934, in the same year as, though happily not before, her daughter, Mme. Joliot-Curie, and son-in-law, M. Joliot, had made another fundamental step forward by the discovery of artificial radioactivity, the more notable as until then the aloofness of radioactivity from all external influences and the impossibility either of altering it in the natural radio-elements or imitating it in the inactive elements had been easily its most outstanding characteristic.

Under bombardment by suitable high-speed atomic projectiles many, if not most, of the common inactive elements can be made to give an evanescent radioactivity. This had often been tried before, without success, and the advance was entirely due to the almost incredible delicacy of modern single-atom methods coupled with the power of the valve to magnify these infinitesimal effects almost without limit. But since for this purpose, though the original discovery was made with the natural α-rays of polonium, artificially generated projectiles serve, they again may be multiplied by suitable electric generators almost without limit. So that already the monopoly of radium in its main practical use in therapy is threatened; radio-sodium obtained by bombarding common salt with heavy hydrogen atoms, which has a half-period of 15·5 hours, has already been prepared comparable in activity to the naturally radioactive elements, and the price of radium has in consequence notably diminished.

Thus Mme. Curie died just as her daughter and son-in-law, in turn, had broken through the barrier which guards the future, and this handing on of the torch of discovery from father to son and from mother to daughter, which it would be difficult to parallel in the history of science, is peculiarly appropriate in the science that first showed that even the chemical elements are not immune from the processes of birth and death.

At the time of her death, Mme. Curie had just finished a new book on radioactivity, and this now appears posthumously after having been prepared for the press by her daughter and son-in-law—a little tardily, perhaps, as the date 1935 appears on the title-page. It is in one volume, about half the length of her much-esteemed "Traité de Radioactivité" of 1910, and is expressly intended for the student rather than the specialist, covering the lecture courses she had given at the Sorbonne. Part 1, occupying about one fourth the whole, deals with ionization of gases, cathode-, X- and positive rays, and it is not until Chapter vii that radioactivity is commenced. The disadvantages of this are, in my view, very serious. For the student is taken in detail through, for example, all the work subsequent to the Great War on isotopes by the positive-ray method and a great number of other topics inspired by and often arising directly out of the progress of radioactivity before the War, before any mention even is made of the parent subject. To make matters worse, when he does arrive at the second part, he is plunged into all the details of radioactive *families*, the formulæ governing the accumulation of radioactive matter, the isotopic constitution of the radio-elements, without any preliminary account of atomic disintegration, the evolution of the chemistry of the radio-elements and the idea of isotopes, or, indeed, any general conspectus of what radioactivity is, except what he already knows from popular hearsay or the study of earlier works.

Chacun à son goût. The beginner to-day has little enough time or breath for what is never going to be the subject of an examination question. He gets here in five hundred pages a careful and clear description of a many-sided subject, copiously illustrated with a large number of striking radiographs both of the earlier and later single-atom methods of examining these new radiations. Rarely can those to whom the task of writing such books usually falls claim to be as intimately versed in the subject. It is a monument to the indefatigability of modern scientists, to whom nothing is too trivial for elaboration, nothing so infinitesimal that it cannot be magnified into investigability. But from another point of view it is also a tombstone of what was once a living subject, erected as a guide to the budding licentiate to satisfy the examination system. It sacrifices historical to logical order and the convenience of treating each section as it arises comprehensively so that it need not be reverted to. It is somewhat disconcerting to find that a subject so new and upsetting has already arrived at the stage of being just one more burden on an overloaded curriculum, all the more so as it is one in which the general principles only are essential, and these belong to the fundamentals of all physical science. It is the ideas, their evolution and the form in which they first appear to the human consciousness that it is most important to preserve; the rest is technics.

If we go back forty years to when Mme. Curie began her work, though chemists at least had a clear idea of the difference between atoms and molecules, the very existence of such energy as will keep her radium alight undimmed for centuries after she has gone was not even suspected, transmutation was universally shunned as an ancient chimera, prominently connected with fraud, and the chemical elements in all seriousness were regarded as homogeneous. It may be convenient to derive everything from the theories that grow up afterwards concerning the constitution of the atom, whatever these may happen at the moment to be, but these are the consequences of new knowledge, whereas it is the origins which should have the first attention of the would-be discoverer. Admittedly it is more difficult to convey to the student the general idea of fog, uncertainty and incomplete knowledge out of which discoveries take their rise. The modern theory has it all so pat and glib, though the truth is stranger than fiction.

If in the space of a lifetime the history of discovery can be so completely inverted or forgotten, one wonders sometimes whether there is any truth at all in what passes for the history of more remote events. It is fortunate that in this field the subject has entered on a new lease of life with the discovery of artificial radioactivity, and that Mme. Curie's last book may prove to be not merely the end of an epoch but also the beginning of a new one, so felicitously begun by her own daughter. *La reine est morte. Vive la reine!*

FREDERICK SODDY.

Earthquakes

Earthquakes
By N. H. Heck. Pp. xi+222. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1936.) 16*s*. net.

ON the concluding page, the author gives the titles of some text-books on general seismology that have been published in the United States, England and Germany. As the last of them dates from 1923, there is clearly room for a new book in which the more recent advances in our knowledge are described. The author is the chief of the Division of Terrestrial Magnetism and Seismology of the United States Coast and Geodectic Survey, and he is therefore in constant touch with the important work that is being carried on in the United States and especially in the State of California.

As the book is designed for the general reader in the United States, the examples and illustrations of the various phenomena are naturally drawn from the earthquakes in that country, especially from such great earthquakes as those of New Madrid in 1811 and 1812, the Owens Valley in 1872, Alaska in 1899, and California in 1906. While this, to a certain extent, increases the usefulness of the book for the European student of seismology, in another sense it somewhat narrows its scope, for, even in these great earthquakes, certain phenomena were inconspicuous, such as the seismic seawaves and the long trains of after-shocks that are connected with the earthquakes of other lands. These subjects are referred to indeed, but too briefly to be of much service.

With these exceptions, the ground is well and carefully covered, the phenomena are clearly described and most of the illustrations are excellent. Among the chapters of greatest interest are those on the causes of earthquakes, including what are known in the United States as 'trigger forces'—a term that it is to be hoped will never become current in Great Britain—on earthquake study with instruments, with good descriptions and illustrations of recently made seismographs, on earthquake records and their interpretation, the location of earthquake epicentres and foci, and on regional investigations in the United States, a chapter that occupies nearly one fifth of the book.

Two other chapters are welcome innovations in the usual text-book course. In that headed "Descriptions of Great Earthquakes", are given brief accounts of seventeen disastrous shocks since

1755, accounts that in most cases furnish the main facts, though omitting the remarkable seiches of the Lisbon earthquake of 1755 that were observed in the lakes of Scandinavia and the north of Scotland. Again, the last chapter contains a brief summary of the "History of Seismology", beginning with the work of John Michell—a most useful feature. In a new edition, the names of seven workers that are wrongly spelled should be corrected. C. D.

A Colour Code for Biology

Code universel des couleurs
Par E. Séguy. (Encyclopédie pratique du naturaliste, Vol. 30.) Pp. lxviii+55 plates. (Paris: Paul Lechevalier, 1936.) 60 francs.

WE have many times collected flowers and animals for our scientific friends. They have always been insistent that we should note their colours. For this purpose we have lately used a colour chart sold by a well-known philatelic shop, but, in resulting publications, we have observed that our colour terms are seldom accepted. Now a French entomologist presents us with a seriously thought out colour-code, founded on the three basic colours, blue, red and yellow, which, when mixed as on a rotating disk, may be made to yield all the colours of the spectrum.

This code covers 48 plates with 15 tints on each, numbered 1 to 720, and the colours may be conveniently quoted by number which, if desired, can be preceded by the spectral terminology for the series. Cover-slip sheets with a suitable aperture through which to view the colours are provided, and it is advised to use the same, choosing a slip of a colour complementary to that of the shade isolated. An example is given, a coloured plate showing three kinds of water-lilies: "Feuilles: vert 388—Fleur supérieure: blanche—Au milieu à gauche: *Nuphar luteus*, fleur, jaune 257—A droite et en bas: *Nymphæa hortorum*, fleur, face supérieure des pétales, rouge 154, face inférieure, rouge 181."

The reviewer's determinations work out better by daylight than by artificial light, and with a white slip rather than with those of the complementary colours. Tested with *Chrysanthemum* petals and some butterflies, our results were distinctly good, each object being laid on the coverlip alongside the shades of colour in rotation. As a practical example, consider a few of the various blues which may be mentioned by artists and scientific men—and let the reader decide whether he is capable of determining all these with accuracy from isolated specimens: turquoise, jade, Antwerp, Gentian, sky, marine, flax, peacock, cyanine, swallow, steel, ultramarine, lavender, royal and Prussian. All are fairly clear on the charts, but the last four are blue-violets.

Great credit is due to the publisher in the production of these charts, and, if necessary, they can obviously be repeated. The physicist has his own methods of enumerating colours, but the naturalist demands something simpler. If he requires the greatest accuracy, would it not be worth his while, whether botanist or zoologist, to test out this code—and if approved ask for its official adoption wherever possible? Any normal individual of reasonable intelligence can very quickly master its use, and thus save himself and his correspondents worry and doubt.

Sea Dayak Textiles

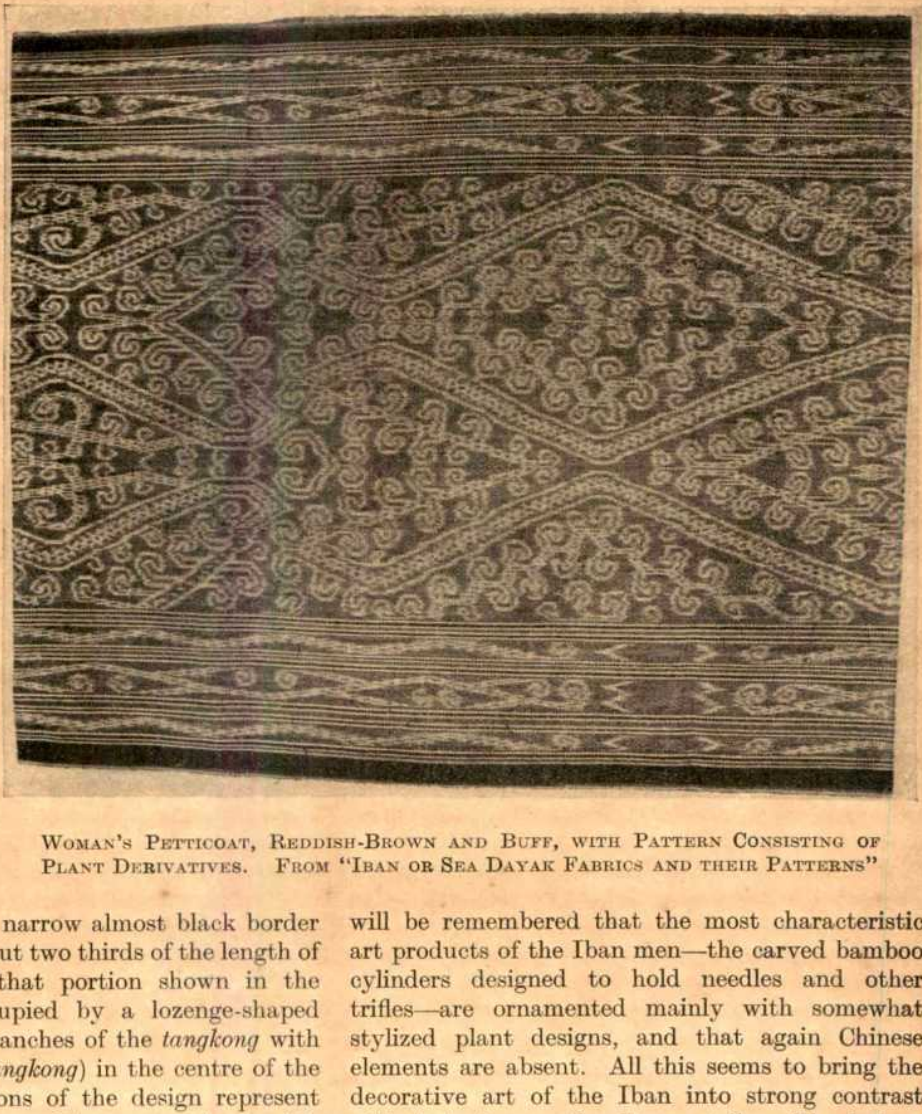
Iban or Sea Dayak Fabrics and their Patterns: a Descriptive Catalogue of the Iban Fabrics in the Museum of Archaeology and Ethnology, Cambridge. By Alfred C. Haddon and Laura E. Start. Pp. xv+157+36 plates. (Cambridge: At the University Press, 1936.) 25*s*. net.

IN this volume Dr. Haddon has returned to one of his early interests, the decorative art of a less advanced community. We are given a study of the designs and patterns on the specimens forming the Cambridge and British Museum collections of Iban (Sea Dayak) cloths, of which the best known and most numerous are the petticoats worn by women. These are always highly patterned, the designs being for the most part so conventionalized that it is impossible to tell what they represent by mere examination. The identification, that is, naming, of the elements of design on the cloths of both collections is due to the late Charles Hose. These are taken as authoritative, and it is upon them that the work is based.

The Iban are a smart, rather dressy people, and both sexes are fond of ornament; the women are expert weavers, producing their complicated and admirably spaced patterns with no other guide than knowledge of conventional design and appreciation of the space to be covered. They have rather a full palette of colours, red, yellow, blue, black, brown and white all being included.

As to the designs themselves, these represent men, crocodiles, deer, shrews, birds, spiders, centipedes, leeches, scorpions, various insects, and plant designs, besides natural phenomena such as clouds. To these must be added a minority of patterns derived from objects of everyday life. All, with the exception of the anthropomorphs (which include a few designs called frogs) and the crocodiles, are so conventionalized as to be unrecognizable without expert instruction.

An example rather simpler than most is reproduced herewith. This cloth is just over 4 feet long and 21 inches broad. Most of the patterns are derived from plants. The background is reddish brown and the patterns upon it are in buff. The main pattern is edged on each side with three longitudinal stripes in varied colours, with a narrow almost black border at the outer edge. About two thirds of the length of the cloth, including that portion shown in the figure, is mainly occupied by a lozenge-shaped arrangement of the branches of the *tangkong* with its "flowers" (*bunga tangkong*) in the centre of the lozenge. Other portions of the design represent *pating betula*, "branches pushing one another back", and *daun tangkong mulai*, "leaf of the *tangkong* twisted back", as well as other plant derivatives. About one third of the cloth (not shown in the figure) has a somewhat degenerate deer pattern, with strikingly developed antler derivatives. The borders consist of two stripes of *daun wi*, "tendrils of ratan", with between them one line of *entibap* (*Arenga saccharifera*).



WOMAN'S PETTICOAT, REDDISH-BROWN AND BUFF, WITH PATTERN CONSISTING OF PLANT DERIVATIVES. FROM "IBAN OR SEA DAYAK FABRICS AND THEIR PATTERNS"

Thirty-six plates are devoted to illustrating the designs, as well as a number of the cloths themselves. Turning these over, the reader is immediately struck by the absence of obvious foreign influence. Apart from a few deer designs, which probably are not dragon derivatives, though it might be possible to construe them as such, there is nothing that can be ascribed to foreign intrusion, a rather remarkable fact considering the Chinese influence that has been exerted in Sarawak. It will be remembered that the most characteristic art products of the Iban men—the carved bamboo cylinders designed to hold needles and other trifles—are ornamented mainly with somewhat stylized plant designs, and that again Chinese elements are absent. All this seems to bring the decorative art of the Iban into strong contrast with that of some other Borneo tribes. The designs must then be regarded as definitely Iban in origin, and a consideration of the objects represented will convince the reader that the authors are right in tracing many of them to the omen animals which play so large a part in Iban religion.

C. G. SELIGMAN.

The Hero:

a Study in Tradition, Myth and Drama. By Lord Raglan. Pp. xi+311. (London: Methuen and Co., Ltd., 1936.) 10*s*. 6*d*. net.

IN this volume, Lord Raglan extends to a wider field the application of certain critical principles which he formulated in his presidential address to Section H (Anthropology) of the British Association. He denies the validity of the methods by which tradition is made the ground of inference as to events in the past, of which documentary evidence, literary or archæological, has not survived. He maintains that tradition, still less the elusive "folk memory", does not endure for more than at most one hundred and fifty years, and that anything claiming to transcend that period is fictitious.

Lord Raglan is not content to rest in destructive criticism. He passes on to show how the 'standardized' heroic traditions came into being. They are, he holds, the concrete part of a ritual, which in most instances can be seen to underlie them, and when regarded at this angle, conforms to the pattern of fertility and cognate rites of an early form of community.

Lord Raglan argues his case ably and well. At the same time, there is something to be said in favour of tradition. Lord Nelson and Napoleon did exist, even though they may appear side by side with the entirely imaginary characters of the folk-drama. Lord Raglan, presumably, would feel constrained to deny their existence, if documentary evidence were absent. That the argument from tradition has sometimes been carried to absurd lengths does not alter the fact that it has served as a useful pointer in archæological argument, as, for example, in the instance of Crete, Troy and other sites of Greek heroic legend. Often such legends must be taken as doing no more than provide the archæologist with a *memoria technica* for cultural movements, contacts and development revealed by archæological research. The argument from tradition, like many other useful things, including Lord Raglan's counter, must be employed with discretion.

Wave Mechanics:

Elementary Theory. By Prof. J. Frenkel. (The International Series of Monographs on Physics.) Second edition. Pp. x+312. (London: The Oxford University Press, 1936.) 20*s*. net.

THIS new edition needs little introduction to readers of NATURE. For the benefit of those who have not studied it, it may be said at once that it is one of the best introductions to wave mechanics extant—complete in itself, clear in development, and not overburdened with mathematical symbolism. The seven sections into which the book is divided deal respectively with light, matter, wave mechanics of a particle, wave mechanics of a system of particles, statistical mechanics, applications to metal theory, heat motion and radiation, and the last section, which is new, is concerned with the theory of chemical forces. Small errors and misprints have been eliminated. The word 'elementary' must not be misunderstood, as, although mathematical developments are not over-emphasized, the work cannot be read with profit by a student who does not possess that knowledge of mathematics necessary to a student of physics of honours grade.

"A little philosophy inclineth Man's mind to atheism; but depth in philosophy bringeth men's minds about to religion." So far Bacon; and some of the enthusiasts who have made far-reaching, and possibly hurried, deductions from Heisenberg's uncertainty principle, might profitably consider the brief, but important section in which Prof. Frenkel deals with Heisenberg's theory of the uncertainty relation to the role of the observer.

Neuroembryology:

Neuroembryology: an Experimental Study. By Prof. S. R. Detwiler. (Experimental Biology Series.) Pp. x+218. (New York: The Macmillan Co., 1936.) 16*s*. net.

A BOOK which gives the exact position of a research subject is always valuable, provided it is accompanied as here by a full literature list. It discusses the factors influencing the growth of nerves, the proliferation of nerve cells and the capacity of the nervous system to adapt itself in response to changed conditions. By experimentation, imposed upon a knowledge of the morphological changes, the dynamics of the developing organism are studied. The data are collected by the examination of the effects in regeneration, by surgical means and by grafting, these leading to hypotheses of the agencies underlying the normal architecture; here the work of Ross Harrison in the last forty years is highly distinguished. Then later there is the study of the growth of nerves *in vitro*, which favours mechanical factors rather than those dependent on hormones, chemotaxis or electrical agents. The whole story of the use and present position of the subject is here told in a pleasant and easy manner, such as will undoubtedly encourage new workers to enter this difficult field.

Ebulliometry

By Prof. Wojciech Świętosławski. Pp. x+196. (Krakow: Jagellonian University Press, 1936.)

THIS is an account of the method of precise boiling point measurements based on the Cottrell principle which has been developed by Prof. Świętosławski and his students since 1925 and applied to a number of physico-chemical problems. Numerous forms of apparatus are described with full experimental details, and this monograph should be useful in directing attention to an experimental technique which has perhaps not yet been recognized in Great Britain at its true worth.

It is a little unfortunate that the translator appears to be more familiar with the idiom of the French language than with English; thus it requires a moment's thought to reveal the significance of "dosing vessels". In general, however, the meaning is clear, and this monograph will be valued not only for its detailed exposition of the experimental methods but also for the discussion of a wide range of scientific and technical problems in which boiling point methods can be used. Progressive Science in Public Welfare and Modern Industry*

THE Department of Scientific and Industrial Research now occupies such an essential place in the scientific and industrial structure of the country that it is already hard to realize that it is little more than twenty years since it first came into existence. The recently issued twenty-first annual report of the Department indicates the remarkable success of the Department in stimulating a new outlook in British industry, and can point to welcome evidence of increased support for research from a considerable number of industries in the last year. The most admirable feature of the report, however, is the lucid and comprehensive picture it gives of the contribution of science to the service of the needs, not merely of industry but also of every aspect of our daily lives, whether as a nation or as private citizens. From the requirements of the defence forces and other Departments of State, to the primary needs of the humblest citizen in respect of water supply, food, transport, clothing and recreation there is scarcely a question to which some contribution is not made by the Department. Moreover, the growing complexity of many of the issues involved in some questions, as food supply, national defence, roads and road safety, render the more valuable such a comprehensive picture as is regularly afforded by the annual report of the Department.

The present report, which covers the period October 1, 1935–September 20, 1936, contains the brief report of the Committee of the Privy Council, signed by the Right Hon. J. Ramsay MacDonald, Lord President of the Council, the report of the Advisory Council, over Lord Rutherford's signature and summaries of the work of the National Physical Laboratory, the Chemical Research Laboratory, and of the various research associations, and research boards or committees.

The gross expenditure of the Department in 1935–36 was £787,186, or £571,831 net as against £549,751 net in 1934–35. The largest single item of expenditure was £109,038 on the National Physical Laboratory, the gross expenditure of £234,383 covering, however, the cost of work carried out at the Laboratory for the Food Investigation Board, the Radio Research Board, and other Research Boards of the Department. Against this gross total, receipts amounted to £125,345, of which £65,950 represents fees from industry for paid work. Other receipts against the gross expenditure of the Department include £63,878 in payments by other Government departments for services rendered, £32,623 from the Road Fund and £9,800 from the Empire overseas for food investigation. Expenditure on the Chemical Research Laboratory was £21,697, on food investigation £43,296 net, on building and road research £78,218 gross, or £33,655 net, on forest products research £38,983 net, on fuel research £87,501 net and on water pollution research £13,968 gross or £4,354 net. Expenditure on the Geological Survey and Museum amounted to £66,641 net, while grants to Research Associations amounted to £108,951 as against £85,384 in 1934–35 and £58,992 in 1933–34.

Special stress is laid in the report on the progress of the Research Associations, and encouraging evidence of development in this field is the increased contribution of the industries concerned to the support of these associations. In the three years since the Million Fund came to an end in 1932–33, this figure has grown from £167,370 to £232,468, and the erection of further buildings and the extension of equipment which have marked the past year indicate the growing faith of industry in the value of research. New laboratories of the Electrical Research Association costing more than £29,000 were opened at Perivale. The Research and Standardisation Committee of the Institution of Automobile Engineers—the co-operative research organization of the motor industry—has acquired and equipped new laboratories costing £20,000 on the Great West Road. The laboratory accommodation of the Paint Research Association has been considerably enlarged. Extensions involving expenditure of £41,000 have been opened at the Shirley Institute (cotton research), where the buildings now cover an area of more than three acres and the total cost of laboratories and equipments has passed £200,000. The income of the Cotton Research Association, the largest of the research associations, has now reached £84,000 and its staff last year numbered 270.

The position of the research association movement as a whole is not, however, regarded as entirely satisfactory. The Department is prepared to provide a further £66,000 for the support of the Research Associations, and would have found that sum in each of the last two years had industry been ready to provide an equivalent contribution. In fact, had full advantage been taken of the offer of the Department, the income of the associations would have been increased by a further £150,000 a year. In some cases only two years now remain in which the industry can earn the balance of additional grant still available. A new development in the year has been the conversion of the Printing Research Association from merely an efficient information bureau, serving the printing industry, the paper-making industry and the printing ink manufacturers, into an organization which adds to knowledge by research. Additional staff has been engaged, and laboratory premises, opened by H.R.H. the Duke of Gloucester on March 9 of this year, have been equipped.

---

* Department of Scientific and Industrial Research. Report for the Year 1935–36. (Cmd. 5350.) Pp. iv+195. (London: H.M. Stationery Office, 1937.) 3s. net.

To turn from the prosaic survey of ways and means to results achieved, it is almost startling that industry anywhere should be so backward in supporting the work of the Research Associations, which makes such important contributions not only to industrial welfare but also to social amenities and well-being. The examination by the Iron and Steel Industrial Research Council of data of works operation, for example, has led to a rapid improvement in productive efficiency and reduction of fuel consumption even in works which were regarded as highly efficient. Moreover, the greatly increased control by scientific instruments in steel making has led to robust apparatus of high precision for such work being made by British firms at prices competitive with foreign apparatus. A comprehensive investigation on steel sheet has been initiated in co-operation with the research organization of the automobile industry. The British Non-Ferrous Metals Research Association has continued its work on the corrosion of copper with particular reference to water service pipes as well as that on the corrosion of lead.

Mainly as a result of the work of the British Refractories Research Association, the life of the silica brick linings of gas retorts is now 25 per cent longer than ten years ago, and the economies resulting to the gas industry are very large. The Electrical Research Association has developed a new type of fuse for radio receivers or electrical clocks which combines a close degree of protection with a greatly increased time lag. Other of its work has been concerned with interference with broadcasting from electric appliances in common use, and with earthing conditions for overhead lines which will protect cattle grazing under them from shock if faults develop on the lines. An interesting investigation carried out by the Paint Research Association of particular interest to the householder is that of painting in winter and in wet weather, and of methods of overcoming the difficulties or ill-effects due to such conditions by simple modification in the composition of the paint.

The close bearing of the work of the Research Associations on everyday life is indeed remarkably illustrated in the present report. A community which is making ever greater use of the motor-car, whether for private or for public transport, can scarcely fail to appreciate the importance of the co-operative research which has made cylinder wear in automobiles no longer the serious problem it presented a few years ago. Gas masks are unfortunately now presenting a civilian interest as well as an industrial interest or one confined to the defence forces of the Crown, but the importance of the work of the Rubber Research Association in developing durable rubber components for such masks and in devising tests to ensure that supplies of reliable articles are available is obvious. Equally of interest, in view of the increasing use which is made of rubber as a constructional material in buildings, is work on the development of rubbers resistant to fire and heat.

Work on rubber is related to comfort as well as to safety, however, and the Association has also been investigating methods of measuring the hardness of rubber which will enable its cushioning properties in reducing noise and vibration to be evaluated more accurately. A particularly interesting piece of work of the Association has been concerned with the resistance to wear of rubber soles and heels, which has enabled the durability of rubber footwear to be increased. The Leather Manufacturers' Research Association has also been concerned with footwear, and has undertaken an important investigation on the quality of sole bands for shoe manufacturers with special reference to the suitability of the leather for light stuck-on soles. The boot, shoe and allied trades have their own Research Association, however, and this has been responsible for an outstanding development in what may be called the initiation of research on walking. To assist manufacturers to design better fitting shoes, the Association has devised a means of making very careful records of the way in which various people walk. A cinematograph record is taken by means of a moving platform or treadmill of the movements of the foot, and is afterwards carefully analysed. The gaits of individuals and the effect of different kinds of shoe upon them are being investigated, and the results already obtained suggest that some shoes are much more likely than others to interfere with the usual gait. The significance of such a contribution from the point of health is difficult to assess, but may well be of great importance.

Equally significant is the work of the Flour Millers' Research Association on the keeping qualities of bread. What the housewife calls 'staling' is usually due to poor keeping qualities in the bread. Bread made in the best possible way from the best possible flour will retain its edibility for ten or twelve days, whereas bread improperly made from poor flour may become unappetizing and almost uneatable in two or three days. The work already carried out suggests that if more attention were paid to commercially controllable factors which promote the good keeping quality of bread, the question of stale bread would be much less serious.

This aspect of bread staling is not, however, true staling, which is caused by a change in the nature of the starch in the bread from its natural form at high temperatures to the natural form stable at low temperatures. If true staling could be prevented, the bread would probably always keep well, but, in practice, methods which would prevent the transformation are liable to accelerate the growth of moulds. Other work of the Association has been concerned with the storage of flour and the fats of flour, while the Research Association for the Cocoa, Chocolate, Sugar, Confectionery and Jam Trades has been investigating the problem of the attack of starch products by insect pests and has already been of much assistance in the suppression of such pests. Other work of this Association on the jellifying properties of various pectins has led to the improvement of conditions for the manufacture of marmalade from oranges.

Many other investigations on food problems, particularly those relating to the storage and transport of food, for which the Food Investigation Board is responsible, are referred to in the report. At the Low Temperature Research Station at Cambridge the lethal effect of X-rays on bacteria has been studied in connexion with the storage of meat. Methods of storing eggs in different concentrations of carbon dioxide are being tried out on a large scale. Another investigation is concerned with the relation between the quality of pork and bacon and the growth and diet of the pig ; and the advantage in dry salt cures of resting the pig adequately before slaughter has been established. The storage and salt curing of herrings, the gas storage of apples, pears and other fruits and vegetables, and canning questions, are other examples of the way in which the work of the Department is tending to improve food supplies and assist in questions of adequate and balanced diet.

Nor are boots and shoes the only point at which the work of the Department touches the clothing of the citizen. The work of all the textile research associations bears closely upon many such matters. The new silk section of the Cotton Research Association, for example, is contributing materially to the solution of problems involved in the use of mixed fabrics of cotton, silk and rayon. The Linen Research Association has been concerned with the laundering of linen fabrics and their resistance to weathering and to fading when dyed, while besides its important work on the resistance of wool to shrinking the Woollen Industries Research Association has been responsible for fundamental research now widely exploited in the 'permanent waving' of ladies' hair. The housewife should be equally appreciative of the work of the Launderers' Research Association on the washing of woollens, on the development of fastness standards for coloured goods and on the properties of detergent solutions.

Reference has already been made to contributions made by the Department in matters of safety. No aspect of the work of the Colliery Users' Research Association is more important than this, whether in respect of dust suppression and the prevention of silicosis, underground illumination or the control of atmospheric conditions in mines. An important investigation has been commenced at the National Physical Laboratory on the production of static electrification in operating theatres of hospitals, which should enable the risks of ignition of anæsthetics by sparking to be considerably reduced. A preliminary investigation on the similar risk in dry-cleaning works has been undertaken at the request of the Home Office.

Among other work bearing directly on health and safety may be mentioned that on industrial respirators and the detection of toxic gases in industry, research on the composition of dental amalgams, their manufacture and use, the radium treatment of disease, atmospheric pollution, in which field a survey on a large scale of the pollution in and round the City of Leicester is to be undertaken, and the investigations in chemotherapy at the Chemical Research Laboratory. Moreover, at the present time, the significance of much of the work of the Road Research Board, whether in road construction or road usage, such as questions of skidding and its prevention, needs no emphasis in this connexion. Work on water pollution, too, has yielded results as important from the health point of view as from that of the considerable savings which have been achieved, for example, for the dairy and milk industry, through the improved disposal of their effluents.

The Building Research Station is scarcely of less importance to the householder than to industry, and besides the improvement of bricks and cements, the durability of building stone and the structure and strength of materials, has covered questions of fire prevention, for which purpose a Fire Testing Station has been opened, and the efficacy of buildings from the point of view of users as regards heating, ventilation, lighting, or the transmission of noise.

The Illumination Research Board has been concerned not only with lighting, or such problems as the effect of glare on vision, but also with problems in connexion with automobile headlights. Space does not permit even mention of other investigations carried out at the National Physical Laboratory or at the Chemical Research Laboratory, by the Forest Products Research Station, the Fuel Research Station, the Lubrication Research Board, in metallurgical matters, furnace design, aircraft design and other fields which have yielded equally significant results for industry or the general advantage of the community. A final reference can only be made to the discovery in radio research, which is one of the most interesting of the year, of the existence of three new electrified regions in the atmosphere between 4 and 40 miles above the earth. These regions are thus well below the well-known Heaviside and Appleton regions, which play such an important part in broadcasting to great distances and in making Empire communication on short waves possible.

Enough has been said, however, to demonstrate the value of the work of the Department alike in the latest fields of scientific activity and investigation and in the very oldest on which industrial prosperity and civic welfare alike depend. No document could in fact be better calculated to show the contribution which scientific research can make to human welfare and progress if it is applied to constructive and social ends, and not prostituted for destructive purposes as in preparations for war.

Boron and the Control of Plant Disease

By Dr. Winifred E. Brenchley

THE value of boron in improving plant growth was indicated in the early part of this century by various workers, notably Agulhon[1], but it was not until 1923 that its essential nature was definitely proved by Warington[2] in her work on the broad bean. Since then, research workers and practical men have taken up the matter all over the world, and various obscure physiological diseases of crops have been traced to a deficiency of boron in the soil. Crown rot of sugar beet, raan in swedes, topsiekte of tobacco and certain leaf-roll diseases of potato all respond favourably to the application of small dressings of borax, usually ranging from 10 lb. to 20 lb. per acre for these relatively short-lived plants. Heavy dressings of boron compounds are unfavourable as they produce toxic symptoms which may cause grave damage.

During the last few years, active experimental work has been carried out in widely separated centres on the control of cork disease, corky core, or internal cork of apples, all apparently representing the same trouble. The surface of the fruit becomes uneven, and brown areas of diseased tissue are distributed throughout the apple, particularly around the core, greatly reducing the market value of the crop.

Acting on a suspicion that the disease was due to the deficiency of some essential element, McLarty[3] tested thirty chemicals by injecting them into the trunks of affected trees. Of these, boric acid and manganese borate proved effective in controlling corky core, as with injections above a minimum of 1·83 gm. per 100 sq. cm. of the cross-sectional area of the trunks no disease occurred, and the total crop was greatly increased. Heavier doses up to 5·92 gm. did not cause any damage to the foliage, though there was slight injury to the bark and cambium at the point of injection. In these experiments the test material was nearly always packed into the trunks in the dry form, because of the greater convenience in handling and also because larger amounts could be used without injury to the foliage.

At the same time, Askew and his collaborators in New Zealand[4] and Jamalainen[5] in Finland were also investigating the problem. In New Zealand boron again proved to be the effective controlling agent out of a large number of elements tested, and the method of getting it into the tree seems to be largely a matter of convenience. Borax spread broadcast at the rate of ½–1 lb. per tree or 50–100 lb. per acre rapidly penetrates the soil to the absorbing zone of the roots in a favourably moist season, and is taken up and passed into the leaves and fruit, giving good control of internal cork. The penetration might not be so good or rapid in a dry season, but there is a considerable safety margin, as the normal annual requirement per acre for leaf and fruit growth has been found by analysis to be only about 14 oz. of borax. Injections of solution containing 0·25 per cent of hydrated borax were equally effective in increasing the boron content of leaves and fruit, and internal cork was prevented by so little as 2·5 gm. borax per tree. Where the injections were made into a branch, a certain amount of migration of boron took place into untreated branches, even when the point of injection was some way above the crotch. Similar control was obtained by applying borax sprays at the rate of one gallon per tree, and the suggestion is made that two applications of a 0·25 per cent solution in spring at an interval of three weeks would prove useful in commercial practice.

In the Finnish experiments[5], boric acid was used as well as borax, and smaller quantities were also tested and proved effective in the control of cork disease. This may be due to a combination of factors, including the type of soil, the different climatic conditions and the fact that the boron compound was watered into the soil. The size of the trees is not indicated, and it is possible that the Finnish trees were younger and smaller than those in New Zealand and so responded to a lower dressing.

Boron deficiency not only damages the tissue of the fruit but also affects the chemical composition, as Jamalainen found that diseased apples contain more glucose and fructose than saccharose, and that the carbohydrates of the actual diseased tissues remain in the starch stage and are not converted. The striking similarity in the results obtained in different parts of the world afford conclusive proof of the value of boron in the control of corky core in apples, and gives rise to the hope that other obscure diseases of fruit trees may also prove to be due to deficiency of some essential minor element, which can be supplied at a relatively low cost and without undue difficulty.

Obituary Notices

Mr. William Taylor, O.B.E., F.R.S.

WILLIAM TAYLOR, who died at the age of seventy-one years on February 27, showed a bent towards engineering early in life, making his own lathe at an age when most children are playing with toys. He learnt from the village blacksmith and the local wheelwright. His first schoolmaster was Dr. Richard Wormald of London, a pioneer in the teaching of science, at whose lectures he assisted as demonstrator. The school was so far advanced in its methods as to have a workshop for metal and wood work. At this time, William and his brother made in their workshop at home, which they had themselves built, a pair of the first telephones ever made in England, and one of the first copies of Edison's recently invented tinfoil phonograph. Later, William Taylor was one of the first students at the Finsbury Technical College, his teachers being Profs. H. E. Armstrong, Ayrton and Perry. He made for Ayrton and Perry the model of their ammeter which is now in the Science Museum. Some of the instruments made in his student days are still in use at the factory he started in conjunction with his brother. The firm thus founded in 1886 was known at first as T. S. and W. Taylor, and afterwards as Taylor, Taylor and Hobson. The founders had the unusual experience of celebrating last year the jubilee of the business they had established.

The firm started by manufacturing photographic lenses, and William Taylor soon saw that accurate lens manufacture depended on accurate screws, so he invented methods of measuring the essential dimensions of screws with a micrometer, using cylinders placed between the threads; he then found it necessary to make his own screw-cutting lathes to produce threads of the necessary accuracy. He also invented the abrupt thread to facilitate the engagement of the lens in its flange. The Royal Photographic Society had proposed standard flange screws, but at first the manufacturers were antagonistic and the Taylor firm was the only one with the necessary equipment to conform to these standards. This experience in exact workmanship was invaluable in the manufacture of the anastigmat, when, in consequence of the reputation of the brothers, they were offered the manufacture of the Cooke lens, the first anastigmat of English design. The inventor of this lens, H. Dennis Taylor, was not related to William Taylor.

In the manufacture of photographic lenses, the need was felt for speedier and neater methods of engraving the mounts than was possible by hand; this led to the design of the engraving machine which, originally intended only for use in Taylor's own works, quickly found a market outside and greatly enhanced the reputation of the firm.

William Taylor next turned his attention to improving the methods of glass working, and practically revolutionized the process of making lenses, so that it became possible to manufacture them in quantity and of high quality. Machines were made for sawing the glass, cutting out disks, roughing to shape, smoothing and polishing, and finally edging. In the design of the automatic grinder, Taylor's work was fundamental. The iron tool fed with loose abrasive, as previously used, quickly lost its shape. He saw that by using a cup-shaped abrasive wheel—he secured one of the first to arrive in Great Britain—any curvature could be produced on the glass by varying the angle between the axes of the revolving work and that of the wheel; wear would not alter the curvature, and could be compensated by moving the wheel forward along its axis.

Great Britain reaped the harvest of these improvements during the Great War, but William Taylor's services did not end there; he made precision tools for munition making (one of the screw thread measuring machines is now in the Science Museum) and redesigned, entirely on his own responsibility, the Army clinometer, so that it was possible to make two hundred weekly of the new design against twenty of the old. In 1919, Taylor, Taylor and Hobson's was one of two Leicester factories which were visited by Their Majesties King George V and Queen Mary.

Mr. Taylor's chief hobby was golf, and he was accustomed to think over and sometimes solve his engineering problems while on the links. He soon became interested in the manufacture of golf balls, adapting his engraving machine to the engraving of golf ball moulds. He himself invented several patterns of markings, and with characteristic thoroughness made a golf ball driving machine to test balls scientifically. A further extension of the engraving machine was the recently invented electric etcher to make possible the marking of hardened steel surfaces quickly and neatly.

Mr. Taylor served on many standardization committees, and obtained a patent for a system of screw thread gauges which he gave to the British Standards Institution for the benefit of the public. This was the foundation of the well-known Wickman gauge. He was also interested in the training of the young engineer and did much, by offering prizes, to encourage a high standard of craftsmanship among apprentices. He gave freely of his time and advice also to Leicester and Loughborough Colleges.

Mr. Taylor took a patriarchal interest in the welfare of his workers and maintained close personal contact with them. His essential kindliness was perhaps masked by a certain dignity, but the employee who might at first feel rather like a schoolboy before the headmaster would soon see the twinkle in his eye as a humorous sally was made, or one of his large store of apt anecdotes was related. It is worth while recording that 'daylight saving' was in operation at his factory years before the Daylight Saving Act. After the War, he introduced a scheme of co-partnership. In his earlier years he had been a Liberal and Free Trader, but modified his views after the War and became a firm supporter of the League of Industry, one of the first branches being started in his works.

Among the honours that fell to William Taylor—all too few in view of his achievements—were the award of the O.B.E., the presidency of the Institution of Mechanical Engineers (in the year of the Ottawa Conference, at which he represented the Institution), and the fellowship of the Royal Society. He was a member of the general board and of the executive committee of the National Physical Laboratory. He was a clear thinker, a good speaker, most thorough in his work, with a passion for accuracy, good design and good craftsmanship. He had a firm belief in the mechanization of industry as ultimately good for the craftsman and craftsmanship, relieving the operator of monotonous physical labour, setting him a higher standard of accuracy, and leaving him more time for the work that calls for the exercise of his higher faculties in the art and science of his craft; the time saved entailing further work in furnishing the instruments of education and recreation, thus providing unlimited progressive development. H. W. L.

Mr. A. R. Horwood

BY the death of Arthur Reginald Horwood, on February 21, British botanists have lost a valued colleague and friend.

Horwood was born at Leicester on May 29, 1879, and was trained for the Indian Civil Service. He failed, however, to pass the medical examination and in 1902 he obtained a post at the Leicester Museum; he was afterwards appointed sub-curator and resigned this post in 1922. Two years later he was appointed temporary botanist at the Royal Botanic Gardens, Kew, and remained at the Herbarium until his death.

Horwood's chief botanical work was concerned with fossil plants and the flora of Europe and the Near East. He published many papers and books, and his popular works on the British flora obtained a wide circulation. The best-known of these were "Plant Life in the British Isles" (3 vols. 1914–16), and "The Outdoor Botanist" (1920). His most important publication was "The Flora of Leicester and Rutland" (1933), written in collaboration with the late (third) Earl of Gainsborough. This contains a large amount of ecological information based on the extensive surveys that Horwood carried out with a band of helpers while at the Leicester Museum. At Kew, Horwood worked in the European and Oriental Department and was chiefly engaged in naming collections of plants from Persia, Iraq and other countries in the Near East.

Horwood was always willing to give the benefit of his advice and help to his many botanical friends and correspondents. He was twice married and leaves a widow and four sons.

WE regret to announce the following deaths:

Sir James Currie, K.C.M.G., K.B.E., chairman of the governing body of the Imperial College of Tropical Agriculture, Trinidad, and director of the Empire Cotton Growing Corporation, on March 17, aged sixty-eight years.

Prof. E. C. Franklin, emeritus professor of organic chemistry in Stanford University, known for his work on ammonia compounds, on February 4, aged seventy-four years.

Prof. J. A. Gilruth, formerly professor of veterinary pathology in the University of Melbourne, lately chief of the Division of Animal Health of the Commonwealth Council for Scientific and Industrial Research, on March 4, aged sixty-six years.

Prof. Duncan S. Johnson, professor of botany in the Johns Hopkins University, on February 16, aged sixty-nine years.

News and Views

Dr. H. L. Eason, C.B., C.M.G.

DR. HERBERT LIGHTFOOT EASON, who has been appointed principal of the University of London, in succession to the late Sir Edwin Deller, was educated at University College, London, and at Guy's Hospital. He has been superintendent of Guy's Hospital since 1920, having previously held the post of dean of the Medical School from 1904 until 1912. He has been a member of the Senate since 1911 and has been vice-chancellor since 1935. He was chairman of the Library Committee in 1929–33, of the Finance Committee in 1923–25, and of the Academic Council for two periods (1922–23 and 1933–35). He served during the Great War as consulting ophthalmic surgeon to the Forces in the Mediterranean, Egypt and Palestine, was mentioned in dispatches, and was awarded the C.M.G. in 1917 and the C.B. in 1919. He has been the representative of the University on the General Medical Council since 1925, and is now junior treasurer of the Council. From 1924 until 1926 he was a member of the Departmental Committee of the Board of Education on the re-constitution of the University, and from 1925 until 1930 a member of the Departmental Committee of the Ministry of Health on Postgraduate Medical Education.

Prof. J. A. Douglas

DR. J. A. DOUGLAS, of Keble College, for many years senior lecturer and demonstrator in the Department of Geology at Oxford, has been appointed to the chair in succession to the late Prof. W. J. Sollas. The professorship carries with it a fellowship at University College. Prof. Douglas's most important work is his classical contribution to the geology of the Andes. He has also done important work on Persian palæontology and stratigraphy, especially the Permo-Carboniferous fauna of south-west Persia. He had published many papers on local geology, especially on the cornbrash sequence of the British Isles, and on other subjects. He has served both as secretary and vice-president of the Geological Society. Generations of students of geology at Oxford have known him as a good teacher—both as tutor and lecturer—and an expert in field geology. The appointment is a popular one, and one that augurs well for the future of geology in the University.

The Flooding in East Anglia

ALTHOUGH on a much smaller scale than the tragic experiences along the valleys of the Rivers Ohio and Mississippi in the United States, and happily, so far, unattended by any loss of life, though the damage to property has been considerable, the flooding of the Fen District in East Anglia has been a source of great anxiety and distress to the unfortunate inhabitants and a matter of grave concern to the responsible authorities. The situation, continuously critical, has changed its aspect but little from day to day during the past week or ten days, except to demonstrate fresh localities of weakness in the over-strained banks of the rivers. Cracks and breaches have occurred at various points and, at the time of writing, some 15,000 acres of good cornland lie under water, while another 150,000–180,000 acres are threatened with a similar fate. The district lies in the South Level area of the Great Ouse Catchment Board, which includes Ely, Soham and Burwell on the east and Earith on the west, forming a basin drained by the Cam, the Lark and the Little Ouse and minor streams. At the moment, the chief source of anxiety is transferred to two main watercourses, the Old and the New Bedford Rivers, artificial channels of the Great Ouse from Earith to the estuary, constructed by Sir Cornelius Vermuyden in the seventeenth century. The two channels run almost parallel about three quarters of a mile apart for a distance of twenty-one miles, and the intervening space, known as the 'Washes', provides a relief for the channels when overcharged, being flooded regularly in the winter and occasionally in the summer months. The two main, or barrier, banks of the enclosure protect the low-lying land on each side, and the maintenance of these banks is a matter of vital importance. The banks are now being taxed to the limit of their resistance.

The Special Areas Act

THE statement relating to the Special Areas, including the memorandum on the financial resolution proposed in the House of Commons on March 8, reviews the work of the Commissioners and the progress in the Areas in public health, social and other services, trading estates, development of industrial and shipping facilities and of the Special Areas Reconstruction Association (Cmd. 5386. London: H.M. Stationery Office). The paper states that the placing of Government orders and the establishment of Government factories in the Special Areas, together with the prospective improvement in the rate position, have prepared the way for a further advance. To assist the introduction into the Areas of new industrial undertakings of the 'light' type and provide more stable, because more diversified, employment, the financial resolution provides the necessary authority for the introduction of a Bill to continue in operation the Special Areas (Development and Improvement) Act after May 31, 1937, to extend the powers of the Commissioners under that Act, and to make new provisions as regards Special Areas and certain other areas to be certified by the Ministry of Labour.

It is proposed to extend the present Act and additional provisions until March 31, 1939, and the resolution provides for the facilitation of the establishment of industry by authorizing the Commissioners to let factories in the Special Areas. It also authorizes the Commissioners to contribute for periods not exceeding five years, not only towards income tax and rates, but also towards the rent payable in respect of new industrial undertakings. Assistance is also to be given to Site Companies established to provide factories in the Areas, and provision is made for loans not to exceed £2,000,000 in the aggregate to new undertakings for their establishment in the Areas. These proposals and the resolution led to a lively debate in which the Government accepted the Opposition suggestion of a Select Committee. Neither the Statement nor the Minister of Labour's speech indicated any rational extension of the boundaries of the Special Areas or redress of existing anomalies, and they are also silent on the questions of training labour and the improvement of communications in the Special Areas.

Transmutation of the Heavy Elements

AT the Friday evening discourse before the Royal Institution on March 19, Lord Rutherford discussed "The Transmutation of the Heavy Elements". During the last few years, our knowledge of the transmutation of the elements by artificial methods has grown with great rapidity, and practically all the known elements have been found capable of transmutation on a small scale when bombarded by fast particles of suitable type. The bombardment of bismuth by fast deuterons is of particular interest as it leads to the production of a radioactive isotope of that element identical in radioactive and chemical properties with the natural radioactive body, radium E. This important result has been confirmed by showing that this artificially produced radium E gives rise to polonium—the first of the radioactive elements separated by Mme. Curie in 1897 from uranium minerals. In general, the neutron is extraordinarily effective in producing transformations in the majority of the elements. In a number of cases very slow neutrons are far more efficient in this respect than fast ones. A suitable source of neutrons for such experiments can be obtained by bombarding beryllium with α-particles from radium. The fast neutrons can be slowed down by allowing them to pass through material containing hydrogen, for example, water or paraffin. In this way more than eighty new radioactive isotopes have been discovered, most of which break up with the emission of β-particles.

THE action of neutrons on the heaviest known element, uranium, has been the subject of close study by Hahn and Meitner during the past two years. Work with this element presents special difficulties on account of its spontaneous radioactivity. The trans-uranic elements produced by neutrons have chemical properties similar to those to be expected from eka-rhenium, eka-osmium, eka-iridium and eka-platinum, corresponding to elements of atomic numbers 93, 94, 95 and 96 respectively. Three new radioactive series are formed, two of which probably arise from the main isotope of uranium (mass 238) after the capture of a neutron, and the third may be due to a less abundant isotope of uranium (mass 235). It does not appear that the bombardment of uranium by neutrons has any effect in accelerating the natural disintegration of this element. A complex series of transformations also arises when the second heaviest element, thorium, is bombarded by neutrons.

Rusting of a Meteorite

EVER since the largest of the meteoric irons found at Cranbourne, about thirty miles south-east of Melbourne in Australia, was extracted from the sand in which it had lain buried for numberless years, it has shown a pronounced tendency to rust. This large mass, which weighed about 3½ tons, was presented to the Trustees of the British Museum in 1862. When first received, it was mounted on a turntable and was shown uncased. So rapid, however, was the rusting that within a short time it was decided to place it in a glazed case and keep the air within as dry as possible by means of frequently renewed supplies of lime. The effect was to slow up markedly the rate of rusting, but not to stay it altogether. It is estimated that more than 4 cwt. of rust has been removed from the meteorite since it reached the Museum. Arithmetically, therefore, it would appear as if the mass had a very long life before it, but it would have been nothing like so long because the lawrencite (ferric chloride), the cause of the mischief, is disseminated in seams and by expanding during alteration tends to split up the mass. Owing to the size and porous character of the meteorite, treatment by a surface coating which has proved so successful with other meteoric irons was out of the question.

ABOUT a year ago, the Trustees on the advice of the Keeper of Minerals decided to substitute for the ordinary glazed case an airtight one which could be filled with dry nitrogen. At the same time the original turntable was replaced by a stronger rigid structure and the mass provided with a firmer bed. During this process forty pounds weight of rust and scale was removed. The nitrogen supply, which is concealed under the bed by the mahogany panelling, consists of the usual cylinder and oil bubblers at the entrance and egress, an extra one at a higher pressure being provided for safety at the egress side. It is necessary to pass the gas slowly through the case because of the impossibility of assuring so large a one being absolutely airtight. The glass and metal are bound together by a special hard cement. A small panel fitted with a gasket has been provided on one of the short sides to give access to the interior when necessary. The first effect of the new method has been to cover the floor of the case with an unusual amount of dust and fragments, the reason being that they had previously been maintained in the cracks or on the surface by moisture which has now gone.

Standardization of Technique in Physical Anthropology

ONE result of the first International Congress of Anthropological and Ethnological Sciences, held in London in 1934, was the establishment of a permanent International Committee for Standardization of Technique in Physical Anthropology. Miss M. L. Tildesley was elected as chairman, and Prof. H. V. Vallois as secretary, until 1938. The records of the subject have been increasing rapidly in recent years, but it is now generally realized that many of the definitions used are not precise enough to ensure that independent workers will obtain metrical or other descriptions which are truly comparable. The techniques used in measuring living people are the least satisfactory, and in this case the personal equations of observers are large enough to falsify many inter-racial comparisons. Miss Tildesley has been making a grand tour in the interests of her committee, and in January she read a paper, entitled "The Problem of Internationally Standardizing Scientific Method", at the meeting of the Australian and New Zealand Association for the Advancement of Science held in Auckland. This dealt more with organization than with any results as yet achieved. The committee consists of 37 members representing 35 different countries, and it is claimed that the fact that it has no permanent seat is an advantage. Different sections of the work are delegated to small groups, and the members of these will be obliged to collaborate chiefly by correspondence. Resolutions of the committee are to be circulated in French versions, with translations in other languages if this is found necessary. An organization of this kind should bear good fruit, even if its principal achievement should be to persuade those who publish new material to give data which will make it possible to estimate the reliability of their records, such as repeated measurements on the same subjects.

John Buist and the Elementary Bodies of Vaccinia

IN the February issue of the *Edinburgh Medical Journal*, Dr. Mervyn Gordon directs attention to the work of Dr. John Buist of Edinburgh upon the microscopy of variola and vaccine lymph, which appears to have been lost sight of. In recent years evid[illegible] has accumulated that the minute agents of virus diseases such as smallpox, vaccinia and influenza, which are capable of passing through fine filters that stop the passage of ordinary bacteria, are particulate. In fact, it is possible to demonstrate tiny spherical or ovoid bodies in most virus diseases by means of dark-ground illumination, or after suitable staining by ordinary objectives. Their size usually lies between 0·1 μ and 0·2 μ, and they are arranged singly, in pairs, or in groups. These granules have been given the name of 'elementary bodies', and accumulated evidence suggests that they are the causal agent of the virus disease, particularly in vaccinia, in which they are frequently known as "Paschen bodies". In a book published in 1887 ("Vaccinia and Variola: a Study of their Life-History"), Buist describes and figures minute bodies which he observed in films of vaccine lymph after prolonged staining with aniline-water gentian violet. Dr. Gordon remarks that there can be little doubt that these bodies described and figured by John Buist (and regarded by him as being the contagium itself) are identical with those afterwards found by Paschen and others and known to-day as the elementary bodies of vaccinia and its causal agent. John Buist was a native of Fife, born in 1846, and was for a time medical superintendent of the smallpox hospital at Barrow-in-Furness. He died in Edinburgh in 1915.

Natural and Artificial Clouds

THE Symons Memorial Lecture was delivered before the Royal Meteorological Society on March 17, by Prof. D. Brunt, professor of Meteorology in the University of London, on the subject of "Natural and Artificial Clouds". Prof. Brunt pointed out that the motions which occur when an unstable layer of fluid breaks down have been found to be in the form of polygonal prismatic cells, in which the motion at the centre of the cell is upward, when the fluid is a liquid. In air, while the motions in deep layers resemble those in liquids, except that the direction of motion is reversed, the motion in shallow layers made unstable by heating from below consists of a large number of ascending currents, surrounded by much slower descending currents. When the air is bounded at its upper limit by a movable glass plate, the shearing produced by moving this plate will give long rolls extending through the whole length of the chamber, if the upper plate is moved sufficiently rapidly. With slower movements of the upper plate, the chamber is filled with distorted prismatic cells, and with very slow movements of the plate, the chamber is filled with rolls transverse to the direction of motion of the plate. These experimental results can be applied to explain a variety of cloud forms, which are thus presumably in part due to the effects of instability. Among these clouds are those which consist of small cloudlets on a background of blue sky, cloud sheets which show a series of clear holes, and clouds in rolls, which may be analogous to either the longitudinal rolls found in the laboratory with rapid shearing of the top plate, or to the transverse rolls found with slow shearing of the upper plate.

Erosion in the Punjab

A CONFERENCE held at Simla recently affords evidence that the importance of the erosion question in the outer Punjab Hills is now receiving serious attention. It was presided over by Sir Herbert Emerson, the other members consisting of the revenue member, the financial commissioner for development, three commissioners of divisions, two deputy commissioners, a representative of the Finance Department, a chief engineer of irrigation, the chief conservator of forests, the conservator of the Eastern Circle and the forest research officer. The assembly of so influential a body shows the importance now attached to this problem by Government. Yet the problem is not a new one. For the last four decades it has been discussed, and men with wide vision have, years ago, foretold the inevitable waste and ruin which would result if the population were allowed to carry on certain practices, including the almost unrestricted pasturage of flocks, more especially goats. The Governments of the day turned a deaf ear. To-day the position has to be faced. Apart from the loss of valuable agricultural land resulting from serious erosion in the hills, part of the water supplies upon which the great network of canals in the Punjab plains depend will be jeopardized unless the extending erosion in the outer hills can be stayed. In several regions of the British Empire this problem of erosion on the large scale and the man-made desert are probably two of the most complicated and most important of the administrative and economic matters facing several Governments.

Education of Young Children

"YOUNG CHILDREN IN EUROPEAN COUNTRIES" is the title of a report recently issued (Washington, D.C.: Superintendent of Documents. Pp. 108. 15 cents) by the United States Office of Education. Among the *sequelæ* of the economic depression in that country none aroused greater concern than the physical and mental handicaps imposed upon young children, and emergency nursery schools were established in 1933–35 in nearly all the States; mostly in already existing school buildings but also in hospitals, camps, mines, mills, etc. As these schools proved their value, it became generally recognized that they had come to stay, and it was determined to ascertain what other countries were doing in this field. The senior specialist in nursery-kindergarten-primary education of the Office of Education was, accordingly, sent on a mission of inquiry to England, Scotland, Belgium, Holland, Italy, Austria, Hungary, Czechoslovakia, the Soviet Union and Poland. Hence the present report, which describes administrative and financial arrangements, housing and equipment and the training of nursery school teachers. In addition, the report deals with health and nutrition and family housing in relation to young children. In scientific planning for the staffing of nursery schools, the Soviet Union is pre-eminent with a network of institutes preparing the teachers who are to take care of the 3½ million children between three and seven years of age for whom nursery and infant schools are to be ready this year. Statistics of attendance in such schools in fourteen countries for 1934 show a maximum of 66 per cent of the population (ages 3–6) in Belgium. France comes next with 52 per cent.

Statistics concerning Non-manual Workers

THE Advisory Committee on Salaried Employees, set up by the International Labour Office at its meeting on November 18–19, reviewed statistics, compiled by the International Labour Office, relating to non-manual workers in different countries, which show the tendencies for the proportion of salaried employees to workers to rise in recent years, to which attention was recently directed at the British Association meeting by Mr. S. W. Stephen. The proportion of women among salaried workers has also risen markedly since before the Great War. In industrial countries, non-manual workers now represent 20–30 per cent of the occupied population. In noting the general tendencies, the Committee recommends that the International Labour Office should continue its studies in this field. Attention was also given to the question of notice of termination of contracts, and opinion was expressed that formal rules should be introduced in this respect in countries where they are not yet in existence. Such regulations should provide for a minimum period of notice to be given by the employer in accordance with the importance of the work performed or its remuneration. A report on the effects of the use of office machinery on conditions of work for staff was also considered, and measures for improving the standing of office employees and protecting them against some of the effects of mechanization were suggested. These suggestions cover essentially the type of work at present being carried out by the National Institute of Industrial Psychology, so far as its resources permit. The protection of the health of employees was also considered, attention being directed to the unsatisfactory conditions in many shops and offices, including warehouses and the premises of forwarding agents, from the point of view of the health, comfort and safety of the staff.

South African Herbage Crops

THE grasslands and forage crops of the British Dominions and Colonies have been the subject of various issues in the Herbage Publication Series, New Zealand and Australia being dealt with in Bulletins 11 and 14 respectively, while papers on research in India and Canada have appeared in *Herbage Reviews*. The most recent addition to this series published by the Herbage Bureau, Aberystwyth, is Bulletin 18 entitled, "Pastures and Forage Crops in South Africa" (Aberystwyth: Imperial Bureau of Plant Genetics. 3*s*.) in which contributions are made by such recognized authorities as I. B. Pole Evans, A. R. Saunders, J. W. Rowland and S. R. de Villiers. The four distinct types of natural pasture, namely, parkland, grassland, desert shrub and sclerophyllous bush are described in detail so that the special problems associated with each of them are clearly i[illegible]ted. The discovery that the general decline in [illegible]ng capacity of the veld had resulted from faulty grazing management has led to a research programme being developed on national lines to enable the natural pastoral resources to be more efficiently utilized. At the same time, the progressive nature of the livestock policy has brought the question of fodder crops to the fore, and more attention will have to be paid to the production of legumes in the future. The importance of breeding work is also recognized, and as a result of the intensive botanical survey recently undertaken, a large and valuable collection of indigenous grasses has been made. From this it is hoped to build up the types of herbage most suitable for the various districts, introduction of grasses from Europe or America being largely ruled out owing to the differences in climatic conditions.

Research at Apia Observatory

THE annual report for 1933 of the Apia Observatory, an institution which is controlled by the New Zealand Department of Scientific and Industrial Research, contains seismological, meteorological, magnetic and electrical data for Apia (western Samoa), and climatological summaries for a number of islands in the South Pacific. The electrical data refer to atmospheric electricity, and were obtained under the guidance of the Department of Terrestrial Magnetism at Washington, D.C., U.S.A., as in former years. They include observations made with Benndorf electrometers. A tide gauge was maintained, and copies of the tabular records were supplied to the United States Coast and Geodetic Survey at Washington. In the more ordinary meteorological work, seventy soundings were made with pilot balloons, to give information about the upper winds. Another activity in that section was the preparation of daily synoptic weather charts. The material for these was collected by Apia Radio Station. Twenty observing stations from various islands contributed to this, thus forming the nucleus of a synoptic network. Material of the kind included in this report forms the observational basis of text-books of world climatology, but the report keeps to the statistical type of presentation, no attempt being made to relate the results to those obtained in other parts of the world.

Cancer Research at the Franklin Institute

AN illustrated brochure has recently been published by the Biochemical Research Laboratories of the Franklin Institute, Philadelphia, describing the aims of the Foundation, which previously was known as the Cancer Research Laboratories. It is pointed out that research has extended from studies of cancer alone to other phases of life and disease, so that it appeared suitable that past research done on the cancer problem should be made an avenue of approach [illegible] more general area of other diseases. The aims [illegible] ation are the study of the processes of [illegible] emical point of view, the study of [illegible] ical compounds with regard to their [illegible] medicinal and beneficent values and the [illegible] longevity and the diseases of age, with the [illegible] of prolonging the span of life. The booklet points out that the investigators at the Institute work as a team, although grouped in the three departments of chemistry, physics and cytology: the director is Dr. Ellice McDonald. The library is an important feature of the Institute, with more than 16,000 classified reprints with author and subject reference. The brochure concludes with a list of 101 papers published during the past nine years from the Institute or the Cancer Research Laboratories.

Standards of Telephone Transmission

IN the Engineering Supplement to the *Siemens Magazine* of January, W. H. Grinsted discusses the problem of the standards used for the assessment of telephone transmission. The wide range of variation of many of the factors involved makes the problem a very complex one. The factors affecting transmission may be divided into the conditions associated with the users, including their own peculiarities, and the plant provided by the administration. Transmission is said to be satisfactory when two subscribers can converse without misunderstanding or strain. During the last four years, experiments have been made in the Siemens' laboratories on a method of transmission testing for 'satisfactoriness' based on this definition. Measurements of satisfactoriness are often made by sending speech to the limit of intelligibility or using nonsense syllables (logatomes), but neither represents conditions similar to normal operation. The latest American scheme is to use 'judgment observations', that is, personal preference as the criterion. The objection to this method is that different persons give very different reasons for preferring one circuit to another. In the method described by the author, the quality of the transmission is measured by noting the number of times that the listener's attention is diverted by the need for conscious effort to understand a word or phrase. The method is highly subjective, but this is necessary if it is to take into account some important factors. The limitations of the method are also discussed.

Universities and War

IN Great Britain there is some difference of opinion as to the purpose of university education. In Italy the question has been definitely settled. What follows is a translation of the beginning of the preface to "Nozioni di Balistica Esterna", by T. Levi-Civita and U. Amaldi (Zanichelli, Bologna, 1935): "The Supreme Council of Defence has requested that University programmes of studies in every subject shall comprise, as an integral part of the course, the theories that more directly concern Military Science and Technique; and in particular has pointed out the claims of External Ballistics to be included in the Theoretical Mechanics Course. We have accordingly thought it our duty to complete with this appendix our Compendium of Theoretical Mechanics (Zanichelli, Bologna, 1928), which has been drawn up to conform with the programme of a regular course at a University or Higher Engineering College. The Contents of this Appendix faithfully follow the programme suggested by the aforesaid Supreme Council of Defence. . . ." We should like to see the corresponding programmes for other subjects, including theology. Presumably that for literature would include Nietzche's dictum "Man is made for War . . . ; all else is folly".

Literature on Water and its Pollution

A VALUABLE summary of abstracts of current research upon water and its pollution, prepared by the Water Pollution Staff of the Department of Scientific and Industrial Research, is issued monthly. In the January number (**10**, No. 1, 1937. H.M. Stationery Office. Price 2*s.* net) the matter deals with a variety of subjects grouped under "Water Supplies", "Analysis and Examination of Water", "Sewage", "Trade Wastes" and "Pollution of Natural Waters". The abstracts are fair summaries of the original literature.

Telephone Loudspeakers for Group Conversations

WE learn from the Soviet Union Year Book Press Service that a telephone loudspeaker to enable several persons to take part in a telephone conversation has been designed by the radio and telephone workshop of the Moscow Province post office administration. The apparatus consists of a loudspeaker and microphone instead of the ordinary handset. The microphone can be placed at a distance of three feet or more from the persons taking part in the conversation. If desired also, several telephone lines can be connected with the apparatus at the same time. It is operated with 110–120 volts alternating current. Thirty of these new devices have already been made. It is not stated for what purposes they are intended. They might be useful for a teacher or lecturer who wanted to address several small classes simultaneously, although the classes were at considerable distances apart.

Radcliffe Travelling Fellow in Astronomy

FOLLOWING nomination by the University of Oxford, the Radcliffe Trustees have elected Dr. H. Zanstra, of the University of Amsterdam, to the post of Radcliffe travelling fellow in astronomy for the three-year period commencing October 1937. Dr. Zanstra, formerly a National Research Fellow in the United States, has held university posts at Seattle, the Imperial College, and Amsterdam, and has carried out observational work at the Dominion Astrophysical Observatory, Victoria. He is best known for his theory of the origin of nebular luminosity, for his observational determination of the temperatures of the nuclei of planetary nebulæ, and for his investigations of the effects of radiation pressure on the stability of nebulæ.

The Night Sky in April

BETWEEN April 1 and 30, the nights shorten in the latitude of London by nearly two hours. Summer Time comes into operation on April 18. New moon occurs on April 11 at $5{\cdot}2^h$ and full moon on April 25 at $15{\cdot}4^h$. If the evenings are clear, 'earthshine' on the moon may be observed from about April 13 until April 16. The planet Venus, which was conspicuous in the evening skies of last month, draws rapidly towards the sun's position until inferior conjunction takes place on April 18 ; next month it will be seen as a morning star. Mercury, which is usually rather a difficult object in the latitude of Great Britain for naked-eye observation, is at greatest eastern elongation (20° E.) on April 20. The planet is in conjunction with Venus on April 7 at 15^h. On April 12 at 8^h Mercury and Uranus are in conjunction, and at 12^h on the same day there is a conjunction between Mercury and the moon which is then just over a day 'old'. Mars rises before midnight and is placed not far from Antares. Jupiter is a morning star, rising at about $2\frac{1}{4}^h$ in the middle of the month. Saturn, rising in the dawn, is not conspicuous. By 22^h in mid-April, the winter constellations of Taurus, Orion, Canis Major and Canis Minor with their bright assembly of stars have nearly set in their entirety, whilst Vega has risen in the north-east, and Arcturus is about $2\frac{1}{2}$ hours east of the meridian. The constellations on or near the meridian at this time offer several attractive objects for telescopic observation—the bright double stars of γ Leonis (separation about 4″), *Castor* ($4\frac{1}{2}''$), ξ Ursæ Majoris (1″), γ Virginis (6″), and α Canum Venaticorum (20″). Messier 51 at R.A. $13^h\ 28^m$, Dec. $+47{\cdot}4°$ (epoch 1950), which is one of the best known spiral nebulæ, requires of course a large telescope and the photographic plate to resolve its structure. Messier 3 at R.A. $13^h\ 40^m$, Dec. $+28{\cdot}6°$ is a notable globular cluster 18′ in diameter, whilst the "Owl" planetary nebulæ (Messier 97) is at R.A. $11^h\ 12^m$, Dec. $55{\cdot}3°$. The Lyrid meteors may be looked for on and about April 21, their radiant being near the star 104 Herculis. The northern sky should be scanned for appearances of the aurora—more particularly when a large sunspot is crossing the sun's disk.

Announcements

MR. T. E. HARVEY (Independent Progressive) has been elected M.P. for the Combined English Universities in the by-election caused by the death of Sir Reginald Craddock. Mr. Harvey was formerly an assistant in the British Museum and warden of Toynbee Hall.

DR. H. J. MULLER, the distinguished Russian geneticist working with Prof. N. I. Vavilov, informs us that on March 15 he arrived at Valencia and was proceeding to Madrid for work with the Canadian blood transfusion unit. Dr. Muller states that he hopes to resume later the work in genetics which he had been carrying out in the Soviet Union, and which his colleagues there are continuing in his absence.

THE report of the Third Correlation Tour undertaken by the Soil Surveyors' Executive Committee has just been published by the Ministry of Agriculture, for England and Wales, and the Department of Agriculture for Scotland. The w[illegible] committee is to correlate soil series examined [illegible] by soil surveyors in different parts of the [illegible] and its third report refers particularly to the B[illegible] Reading and West Midland Provinces and to Wales. Copies of the publication may be obtained gratis on application to the Ministry of Agriculture, 10 Whitehall Place, London, S.W.1.

THE Laboratory of Industrial Hygiene has been incorporated under the laws of the State of New York as a non-profit organization empowered to carry on scientific and industrial work in chemical, bacteriological and general public health problems, and to accept grants for definite scientific purposes. The president is Dr. William Hallock Park. The laboratory includes at the present time the following units : a certified milk laboratory under the direct supervision of Dr. Park, a vitamin-testing laboratory, a clinical diagnostic laboratory and chemical and bacteriological laboratories.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 553.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

New Knowledge of the Life-Cycle of Malaria Parasites

WE wish to direct attention in this letter to an interesting result of our work at this Institute on the malaria parasite of the domestic fowl, which Prof. Brumpt, of Paris, found and described in 1935 and to which he gave the name *Plasmodium gallinaceum*[1,2].

This parasite, like other members of the family Plasmodiidæ, has a schizogonic cycle of development in the circulating red blood corpuscles of its vertebrate host (the domestic fowl) and a sporogonic cycle of development in its insect host which, as Brumpt has shown, is the yellow fever mosquito *Stegomyia fasciata* (*Aedes aegypti*). But it appears from our work that it has, in addition, a hitherto unrecognized schizogonic cycle of development occurring in reticulo-endothelial cells of the spleen, liver, kidneys and other internal organs and particularly, in certain cases, in the reticulo-endothelial cells which line the capillaries of the brain.

The first step in this finding was that in January this year, one of us (S. P. J.) observed in the cytoplasm of endothelial cells from the spleen and heart blood of a chicken which had died from the malarial infection, unpigmented schizogonic phases of a parasite which bore no resemblance to the pigmented 'sporulating' or 'pre-sporulating' stages of the malaria parasite occurring in red blood corpuscles. Provisionally we called these phases "x bodies". Then a search of the literature showed that in 1935 Clay Huff and Bloom[3], of the University of Chicago had found what seemed to be the same phases in erythroblastic and lymphocytic cells of the bone marrow of birds infected with *Plasmodium elongatum*, and that in 1936 Prof. Raffaele[4] of the Marchiafava Institute for Malariology in Rome had found what are certainly the same phases in the reticulo-endothelial system of birds infected with *Plasmodium relictum*. The interpretations given to their findings by these observers are not at all the same, but this seems to us to be less important than is the fact that observers working independently in three different countries on three different species of avian plasmodia have found that at any rate some malaria parasites have an additional cycle of development in the vertebrate host which was previously unknown.

As regards the life-history of human malaria parasites, the occurrence of such a cycle in tissue cells instead of in red blood corpuscles was postulated by several investigators some years ago in an endeavour to explain why quinine is ineffective in preventing attacks of malaria due to the bites of mosquitoes and in preventing the relapses or recurrences which are such a troublesome feature of the human disease. In this connexion, we have repeated on chickens infected with *P. gallinaceum* some of the prophylactic and curative clinical trials with quinine and the synthetic antimalarial drugs which were made on other avian and on human plasmodia in 1931 and later years, and the results seem to indicate that the discovery of the endothelial cell cycle of the parasite opens up an entirely new field for chemotherapeutic research and may help to explain some of the clinical, therapeutic and epidemiological problems of malaria which hitherto have remained unsolved. We think this conclusion is justifiable despite the fact that as yet the discovery has been made only on bird malaria.

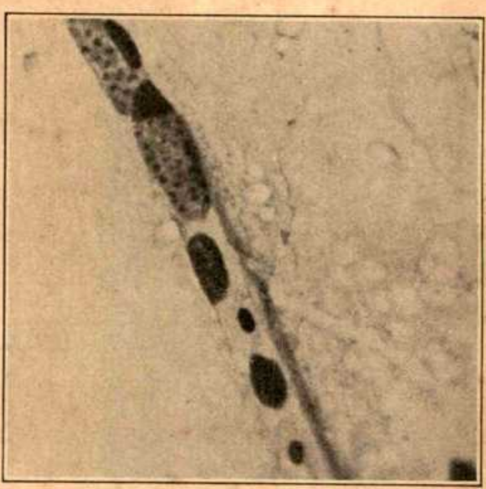

Fig. 1.

At a laboratory meeting of the Royal Society of Tropical Medicine and Hygiene which was held at the Royal Army Medical College on March 18, we showed a series of preparations of various stages of the cycle, including examples from birds which had been temporarily cured of the peripheral blood infection by quinine, but had died later as a result of the uninterrupted development of large schizonts in the endothelial cells lining the capillaries of the brain (Fig. 1).

We should like to add that the discovery, apart from its probable bearing on clinical and therapeutic problems, raises a question of interest to systematists in that it does not seem correct any longer to define the Plasmodiidæ as a family in which the whole of the vertebrate cycle of development occurs in the red blood corpuscles. *P. gallinaceum* is evidently a parasite which, in the vertebrate host, has a cycle of development similar to that of other members of the family Plasmodiidæ but, in addition, it has a cycle of development resembling, in some respects, the schizogonic cycle in endothelial cells which is ordinarily described as being characteristic of members of the family Hæmoproteidæ.

Observation of Ultracentrifugal Sedimentation by the Toepler *Schlieren* Method

For the observations of concentration distribution in an ultracentrifuge cell during the process of sedimentation, methods depending on light absorption or refractive index have been used[1,2]. According to the latter procedure, as used in the sedimentation velocity measurements, a scale is photographed through the cell; from the measurements of the displacement of the scale divisions in the distorted image on the photographic plate, the concentration gradient in different parts of the cell is calculated. The resulting gradient diagrams show the number of components present, and their sedimentation velocities and concentrations can be accurately calculated.

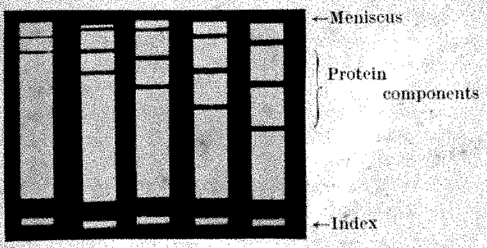

Fig. 1.

Sedimentation pictures of hæmocyanin from *Limulus polyphemus* at *p*H 6·8. 5 min. between exposures. Centrifugal field: 120,000 times gravity. Cell thickness: 12 mm. The black bands represent the three components sedimenting most rapidly.

The well-known Toepler *Schlieren* method, also depending upon the deviation of a beam of light in a concentration gradient, has been used for many similar purposes[3]. Recently, one of us (A. T.) applied this procedure to electrophoresis measurements with quite satisfactory results[4]. The method has now been tried in observations of sedimentation velocities; some examples are given in Figs. 1 and 2. The following optical arrangement is used (Fig. 3): A lens placed as closely as possible behind the centrifuge cell projects an image of a horizontal slit through the cell on to the camera objective. In front of this is a vertically movable screen, having a horizontal edge with which any part of a deviated image of the slit may be cut off. When the screen is properly arranged, any gradients occurring in the cell will give rise to corresponding black bands visible to the eye in the image of the cell and recorded on the plate in the camera, as shown in Figs. 1 and 2. A tungsten ribbon lamp with a condenser lens is used for illumination of the slit.

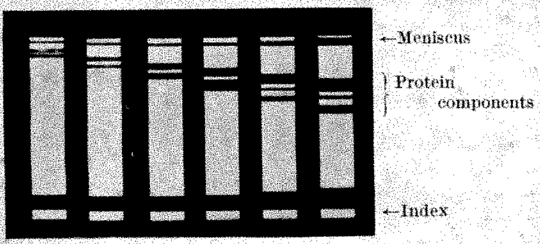

Fig. 2.

Sedimentation picture of a pathological serum (8 parts of serum diluted with 3 parts of a concentrated phosphate buffer). *p*H 6·8. Total salt concentration: 0·25 molar. 10 min. between exposures. Centrifugal field: 350,000 times gravity. Cell thickness: 3 mm. Besides the three components seen in the figure, a fourth slow sedimenting one appeared at the meniscus in later exposures. (Normal serum under the same conditions shows only two components.)

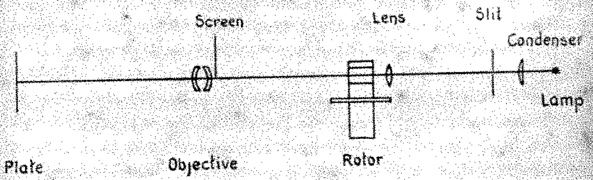

Fig. 3.

The method offers the advantage of rapid and convenient observation of components in mixtures and their sedimentation velocities. It also gives a rough idea of the relative amounts of the differently sedimenting substances. It may be modified also to give a more accurate determination of concentration[5], but for this purpose it does not seem to offer any advantage over the very accurate scale method previously mentioned.

Liquid Crystalline Preparations of Cucumber Viruses 3 and 4

In a previous note[1], we showed that liquid crystalline substances infective at high dilutions could be isolated from solanaceous plants infected with three different strains of tobacco mosaic virus. We have been unable to transmit these strains to cucumber plants, and other workers have found cucumber to be immune to tobacco mosaic virus. From cucumber plants infected with cucumber viruses 3 and 4[2], we have now isolated nucleoproteins with a similar chemical composition and similar in many of their properties to those obtained from solanaceous plants infected with tobacco mosaic virus; they are, however, rather less stable and more difficult to isolate.

Of the methods of isolation yet tried, the following has proved most effective: expressed infective cucumber sap is coagulated by heating to 70° C., centrifuged and the supernatant fluid one quarter saturated with ammonium sulphate. A precipitate consisting of small needles or fibres and giving a satin-like sheen is produced, and this is centrifuged off. The precipitate is now dissolved in water and reprecipitated several times with dilute ammonium sulphate solution and with acid at about *p*H 4·8. If this fails to give colourless solutions, further purification can be effected by high-speed centrifugation or by incubation with trypsin. Highly purified preparations of the cucumber viruses, if sufficiently concentrated, separate into two liquid layers; the lower layer is spontaneously birefringent and the upper layer readily shows the phenomenon of anisotropy of flow.

Systemic infections of cucumber plants were obtained by inoculating 1 c.c. of a solution containing 10^{-9} gm. of these nucleoproteins, and specific precipitates with antiserum were obtained with $1/8 \times 10^{-6}$ gm. No infection of tobacco, tomato, *Nicotiana glutinosa* or Golden Cluster beans (all of which are susceptible to tobacco mosaic virus) was obtained, even when they were inoculated with concentrated solutions.

Purified preparations of cucumber viruses 3 and 4 do not differ appreciably from one another in any of the properties yet investigated, but they differ in some respects from those of tobacco mosaic virus. Their precipitation point with acid in dilute salt solutions is about *p*H 4·8, and in the absence of salts about *p*H 5·5, whereas for tobacco mosaic virus preparations these points are *p*H 3·4 and 4·2 respectively. It is tempting to associate the difference in host range of the two groups of viruses with their behaviour with acid, for the *p*H of expressed cucumber sap is about 7·8 whereas that of tobacco sap is about 5·8.

The preparations of cucumber viruses 3 and 4 are very similar to one another antigenically, and they are also serologically related to those of tobacco mosaic virus. They differ antigenically, however, much more from tobacco mosaic virus than from one another, and much more than the recognized strains of tobacco mosaic virus differ from each other. As yet only preparations of viruses serologically related to tobacco mosaic virus have been found to show anisotropy of flow and to form spontaneously birefringent solutions. From plants infected with five distinct viruses not serologically related to tobacco mosaic virus, we have been unable to isolate any substances with these properties by precipitation with acid or strong salt solutions, although highly infective preparations have been obtained.

With these cucumber viruses, as with those previously described, we have been unable to dissociate virus activity from the liquid crystalline nucleoproteins, but there is no proof that our preparations contain only particles capable of infecting susceptible plants.

We wish to thank Dr. G. C. Ainsworth for supplying us with cucumber viruses 3 and 4, and Mr. E. T. C. Spooner for preparing the antisera used.

Latent Impurities in Electrodes used for Spectrographic Research

THE recent communication in NATURE by D. A. Webb[1] is of particular interest to me because for the last six years a minor part of my time has been devoted to an attempt to evolve a satisfactory spectrographic method for analysing plant material for the twenty or so elements usually present. Great progress has recently been made as a result of invaluable and much appreciated help given voluntarily by Mr. A. L. Tackley from September to January. The resulting method promises to be satisfactory and it is hoped to standardize it shortly. The great importance of the determination of the minor, as well as the major, elements in plant and animal tissues, in view of the increasing realization of their importance to the organism, seems to justify some mention of the progress made in meeting the difficulties mentioned by Webb.

The method consists in preparing small electrodes from the plant material itself without the addition of any foreign substance, except platinum wire, and comparing its spectrogram with that given by one of known composition prepared by adding pure substances to the purest grade of filter paper.

The plant material is kept at 200° C. for 24 hours, after which it is ground in an agate mortar. 0·0035 gm. of the dark brown powder is compressed in a specially constructed press under a pressure of the order of 500 tons per sq. in. around the end of a short length of platinum wire of diameter 0·005 in. The electrode is transferred by its platinum wire to a small specially designed electric furnace, in which the carbonization is effected by heating for five minutes at a low red heat, following a preliminary heating for the same length of time with half the current flowing. Two such electrodes, each measuring about 2 mm. in diameter and 1 mm. long, are held by the platinum wire and sparked in an atmosphere of nitrogen. Practically the whole of the material may, if desired, be disintegrated. It is fortunate that, under the conditions of excitation so far employed, the platinum spectrum has not appeared on the plate.

As is well known, even the purest filter paper contains minute quantities of impurities, mainly calcium and silicon. This admittedly is a drawback, but it is not a serious one, because these elements occur in comparatively large amount in almost all parts of plants. Filter paper has the great advantage for the purpose of being composed of one of the main organic constituents of the plant, namely, cellulose, so that the resulting electrode should resemble closely in texture the one prepared from plant material. Further, by means of specially designed micropipettes, known volumes of standard solutions may be quickly and accurately added to the paper. The pipette is filled by capillarity when its tip touches the surface of the liquid and is emptied by being allowed to touch the filter paper. The pieces of filter paper with their charges of salts are dried and treated in the same way as plant material.

The method, with slight modifications, should be applicable to a variety of types of material. In view of the promising results so far obtained, it will be developed as rapidly as limited man-power allows.

Reaction of Nitric Oxide with Hæmoglobin and Methæmoglobin

THAT hæmoglobin reacts with nitric oxide is well known, but there is no agreement in the literature as to the mechanism of this reaction or the nature of the compound thus obtained.

According to Haurowitz[1], nitric oxide combines only with reduced hæmoglobin in complete absence of oxygen or even in the presence of a reducer (sodium hyposulphite, $Na_2S_2O_4$). Methæmoglobin, according to this author, does not combine directly with nitric oxide, but is reduced by it to hæmoglobin which then combines with more nitric oxide. Anson and Mirsky[2], on the other hand, consider that nitric oxide combines normally with methæmoglobin. They believe that hæmoglobin in presence of nitric oxide is oxidized to methæmoglobin, which then forms the nitric oxide compound. However, their experiments, consisting in injection of hæmoglobin by means of a syringe into a tonometer containing a mixture of nitrogen and nitric oxide, do not exclude the possibility of introducing dissolved oxygen, the latter giving rise to nitrogen dioxide, which may be responsible for oxidation of hæmoglobin to methæmoglobin.

Careful study of these reactions has convinced us that both these interpretations are only partly correct. All our experiments have been carried out in modified Thunberg tubes which received 3 c.c. of 0·5 per cent solution of hæmoglobin or methæmoglobin at *p*H 6·5, unless otherwise stated. The tubes were evacuated, washed several times with pure nitrogen, and filled with pure nitric oxide. According to the experiment, the hollow stoppers of the tube may receive various reagents which can be mixed with the contents of the tubes.

I. *Reaction between Nitric Oxide and Hæmoglobin.*

(1) Solutions of oxyhæmoglobin reduced in Thunberg tubes to hæmoglobin by evacuation, when mixed with nitric oxide, turn distinctly red and show two wide and somewhat diffuse bands at 574·5 mμ and 536 mμ.

(2) The same result is obtained in presence of an excess of sodium hyposulphite added at different stages of the reaction.

(3) This compound is very stable and is not decomposed by the addition of a great excess of sodium sulphite or by washing on an ultrafilter membrane.

(4) Potassium ferricyanide added to this compound after removal of excess of nitric oxide only slowly oxidizes it to acid methæmoglobin.

All this confirms Haurowitz's view that the reduced hæmoglobin combines with nitric oxide forming NO–Hb compound.

II. *Reaction between Nitric Oxide and Methæmoglobin.*

(1) An acid solution of methæmoglobin completely free from oxygen mixed in a Thunberg tube with pure nitric oxide rapidly turns red and its absorption spectrum is replaced by two bands at 568 mμ and 531 mμ. These bands are, however, more distinct than those of NO-hæmoglobin and lie 50–60 A. nearer the blue end of the spectrum.

(2) This compound is obtained in the presence of a great excess of potassium ferricyanide.

(3) A solution of acid methæmoglobin, before it is treated as in experiment 1, is mixed with 10 mgm. of sodium sulphite. When this solution is shaken with pure nitric oxide, the bands of methæmoglobin are rapidly replaced by the two bands at 568 and 531 mμ. On standing a minute or two, the colour and the absorption spectrum revert to those of acid methæmoglobin. This reversion can be repeated several times. Sulphite, on combining with dissolved nitric oxide, liberates acid methæmoglobin.

(4) A Thunberg tube with acid methæmoglobin and a little potassium cyanide in the hollow stopper is treated as in experiment 1. When the red compound with two absorption bands is formed, the cyanide is mixed with the solution and the absorption spectrum of NO-methæmoglobin is replaced by that of KCN-methæmoglobin.

(5) A similar experiment carried out with sodium fluoride instead of potassium cyanide gives only a partial formation of fluoride methæmoglobin. The incomplete reaction in this case is due to the comparatively low affinity of fluoride for methæmoglobin.

(6) If methæmoglobin is treated with nitric oxide at *p*H 5·6 and the tube is evacuated immediately the compound is formed, the NO-compound is almost completely reversed to methæmoglobin.

All these experiments clearly demonstrate that methæmoglobin forms with nitric oxide an easily reversible NO-MHb compound. This compound is, however, very unstable. Its absorption bands gradually become diffuse and move towards the red end of the spectrum. The NO-MHb, soon after its formation, is gradually transformed into a compound which is indistinguishable from NO-Hb, and this change is accelerated if the nitric oxide in the tube is replaced by nitrogen. The fact that this transformation is greatly accelerated on addition of a reducer (sodium hyposulphite) shows that NO-MHb in complete absence of oxygen undergoes reduction to NO-Hb.

Nitric oxide combines therefore with hæmoglobin (NO-Hb) and methæmoglobin (NO-MHb). With hæmoglobin it forms a very stable compound from which free hæmoglobin cannot be easily recovered. With methæmoglobin, however, it forms an easily reversible compound which is not stable and which, on standing, undergoes reduction to NO-Hb.

Aldehyde Mutase

IT is generally believed that aldehyde mutase (the enzyme which catalyses the dismutation of aldehydes in accordance with reaction (1)) is identical with aldehyde oxidase, which oxidizes aldehydes in accordance with reaction (2):

$$(1)\ \mathrm{R{-}CHO + R{-}CHO + H_2O = R{-}COOH + R{-}CH_2OH}$$
$$(2)\ \mathrm{R{-}CHO} + A \qquad \mathrm{+ H_2O = R{-}COOH} + A\mathrm{H_2}$$

where A may be O_2, methylene blue or some other 'hydrogen acceptor'. Wieland[1] suggests that the oxidase normally uses a hydrogen acceptor to produce an oxidation of the aldehyde, but when no other acceptor is present it uses a second molecule of aldehyde as acceptor, reducing it to alcohol and so producing a dismutation of aldehyde (reaction 1).

We find, however, that aldehyde mutase and aldehyde oxidase are two distinct enzymes which can be obtained separately. Oxidase preparations made from milk by the methods of Dixon and Thurlow[2] or Dixon and Kodama[3] are very active in catalysing the oxidation of aldehydes by oxygen or by methylene blue, but we can detect no trace of dismutation of aldehydes by these preparations, even in presence of co-zymase. On the other hand, we have obtained very active mutase preparations by precipitating an aqueous extract of horse liver with alcohol, rejecting the precipitate, and again precipitating the fluid with a mixture of acetone and ether. These mutase preparations are totally unable to oxidize aldehydes either with methylene blue or with oxygen, even after addition of the cytochrome-oxidase system. (Some preparations made by Reichel's[4] method behave similarly, but others contain small amounts of aldehyde oxidase and catalyse both reactions.)

Not only can the two enzymes be prepared free from one another, but also they behave differently in several respects. The mutase is strongly inhibited by iodoacetic acid, which has little or no action on the aldehyde oxidase. The oxidase is completely inactivated by treatment with cyanide, which does not inhibit the mutase. On the whole, the oxidase acts better with aromatic, and the mutase with aliphatic, aldehydes, probably owing to differences of affinity. The mutase is apparently only active in the presence of co-zymase, in agreement with the views of Euler[5], whereas co-zymase is quite unnecessary for the oxidase. (Mutase from dog liver is practically inactive unless co-zymase is added; horse liver preparations appear to contain some co-zymase and are already active, but the activity is greatly increased by adding further co-zymase.)

The mutase preparations produce a rapid dismutation of methyl glyoxal, apparently to pyruvic acid and acetol, about 1 mol of acid being produced from 2 mols of the aldehyde in accordance with equation 1. Boiled mutase preparations of course have no effect. The milk oxidase preparations produce an apparent dismutation of methyl glyoxal, but roughly 2 mols of acid are produced from 2 mols of aldehyde; the product is lactic acid, and the reaction is given equally well by boiled oxidase preparations. This reaction is therefore not enzymatic, but is due to the milk proteins. The same reaction is brought about by glyoxalase, but whereas glyoxalase is inactive without its co-enzyme, glutathione, this system is independent of glutathione.

Most of the mutase experiments were done manometrically by measurement of acid production by the method used by Lohmann[6] and others. The reactions took place in dilute bicarbonate solution in Barcroft manometers, the flasks being filled with a mixture of 95 per cent nitrogen plus 5 per cent carbon dioxide (completely freed from traces of oxygen) before mixing the reactants. The acid then produced was neutralized by the bicarbonate, releasing an equivalent amount of carbon dioxide, which was measured manometrically. Corrections were applied for the 'retention' of carbon dioxide. Serious difficulties were encountered in following the mutase reaction by chemical estimations, but the main points were checked chemically.

The subject is being fully investigated, and the results will be published in detail elsewhere.

A New Biological Stain for General Purposes

It was accidentally discovered while dissecting small Crustacea under spirit on a background of black velvet, that a dye dissolved very slightly in spirit and stained the chitin a distinct green. This observation was communicated to the Dyestuffs Group of Imperial Chemical Industries, Ltd., who succeeded, after investigation, in supplying a suitable dye in the Chlorazol series, which on further experiment was found to act as a very useful general biological stain.

This Chlorazol Black E *Biological quality* stains nuclei and chromosomes black, rivalling iron hæmatoxylin in its effects. At the same time, it stains cytoplasm and secreted products varying shades of grey. It can be used for whole tissues as well as for sections. It is an excellent stain for chitin which it stains green, and probably for glycogen which stains pink or red.

Its main advantages are that it requires *no mordant* and *no differentiation*, but if by chance sections or tissues are overstained, they can be differentiated in terpineol or dilute 'Milton'. It can be used in either alcoholic or aqueous solutions, and as it is only slightly soluble a small amount of dry stain is all that is necessary. A saturated solution in 70 per cent spirit stains ordinary sections in from fifteen to thirty minutes. So far as I have been able to test it, slides do not fade even if left exposed to daylight for twelve months.

A supply of this colour has been reserved by Imperial Chemical Industries, Ltd., and I have tested it and found it to be satisfactory. It can be obtained from any of the sales offices of Imperial Chemical Industries, Ltd.

A Whale Shark rammed by a Steamer off Colombo, Ceylon

Early on the morning of November 23, 1932, the Dutch steamer *Johan van Oldebarnevelt*, Captain Julsing commanding, caught a whale shark on her bow in lat. 7° 5′ N., long. 77° 50′ E.—about 150 miles west of Colombo, Ceylon. The shark (size not noted) was killed, and when the vessel was slowed down it sank. Captain Julsing knows the whale shark and states that this fish in size, shape and colour markings was a counterpart of the other which his vessel killed in 1933—presently to be noted. This phenomenon seems worthy of brief record for a number of reasons. It is an extraordinary thing in itself. Also, it is the second time that this vessel has impaled a whale shark on her bow, and it makes the fifth record of such an extraordinary happening. Finally, it adds another *Rhineodon typus* to the roster of this fish recorded for Ceylonese waters.

In November 1933, the *Oldebarnevelt* struck and killed a whale shark off the Island of Perim, in the Strait of Bab el Mandeb. Fortunately for science, the Dutch ichthyologist, Dr. H. C. Delsman, was on board. He saw the fish hung on the stem of the vessel, positively identified it, and recorded the occurrence in Nature[1].

However, this is neither the only nor the first whale shark rammed by a vessel in the Red Sea. On May 14, 1933, the Italian steamship *Francesco Crispi*, while off Port Sudan, on the west side of the Red Sea about half-way down from Suez, was slowed down by a great spotted shark bent double over the prow of the vessel. The whole matter was investigated and reported on fully with much photographic evidence by Renato Santucci[2].

Still earlier, I had recorded two similar happenings[3]. On July 6, 1924, the Elder Dempster and Co.'s motor vessel *Alba*, in the Gulf of Guinea (lat. 4° 28′ N., long. 6° 24′ W.), ran into a whale shark—breaking its back. Earliest of all, the Munson liner *American Legion* ran afoul of a 30-ft. specimen in lat. 17° 57′ S., long. 38° 41′ W.—near the Abrolhos Light, off the coast of Brazil.

Finally, it is of interest to note that the whale shark rammed by the *Oldebarnevelt* off Colombo, in 1932, makes a fourth definite record of this fish for Ceylonese waters. The whole question of *Rhineodon* in this region has been carefully gone into in a communication published by me in 1933[4]. In this a number of reputed occurrences were shown to be erroneous. In addition to the four whale sharks definitely to be assigned to Ceylon, three have been recorded from the neighbouring waters of southern India—one at Trivandrum and two at Madras. The total count for southern India is, then, at present, seven specimens.

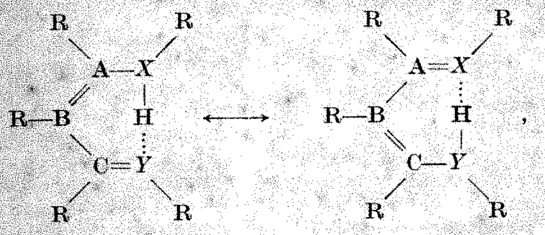
Synchronized Oscillations in Hydrogen Bridges

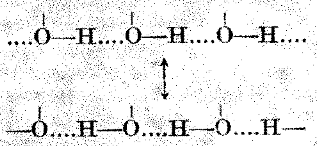
MOST of the compounds now known to contain intramolecular hydrogen bridges can be represented[1] by the formulæ:



in which *X* and *Y* denote oxygen or nitrogen atoms. As indicated, there is undoubtedly resonance between the two extreme structures represented. An equally important but apparently hitherto overlooked stabilizing factor is the tendency of the electron distribution around the ring to shift in synchronism with the oscillational motion of the bridge hydrogen. The electron shifts produced by motion of this hydrogen in the direction *X*—*Y* decrease the *X*—H attraction and increase the *Y*—H attraction. As a result, the small energy hump which would probably otherwise exist[2] in the centre of the bridge is greatly reduced or eliminated entirely, and the bridge stability is increased.

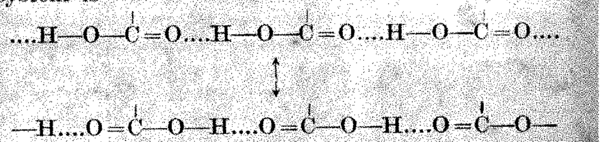
In rings containing two hydrogen bridges, such as occur in the formic acid dimer[3], in β oxalic acid[4] and in isatin[5], the two bridging hydrogens tend to oscillate synchronously, the oscillation of each aiding that of the other.

Synchronous oscillation of the hydrogens of hydrogen bridges suitably linked together in long strings must increase their stability. In resorcinol[6] and in a number of inorganic hydroxides, resonating bridge systems of the type



$$\begin{array}{c}\ldots\overset{|}{\mathrm{O}}\text{—}\mathrm{H}\ldots\overset{|}{\mathrm{O}}\text{—}\mathrm{H}\ldots\overset{|}{\mathrm{O}}\text{—}\mathrm{H}\ldots\\ \updownarrow\\ \text{—}\overset{|}{\mathrm{O}}\ldots\mathrm{H}\text{—}\overset{|}{\mathrm{O}}\ldots\mathrm{H}\text{—}\overset{|}{\mathrm{O}}\ldots\mathrm{H}\text{—}\end{array}$$

apparently exist. In α oxalic acid[4], the resonating system is



$$\begin{array}{c}\ldots\mathrm{H}\text{—}\mathrm{O}\text{—}\overset{|}{\mathrm{C}}=\mathrm{O}\ldots\mathrm{H}\text{—}\mathrm{O}\text{—}\overset{|}{\mathrm{C}}=\mathrm{O}\ldots\mathrm{H}\text{—}\mathrm{O}\text{—}\overset{|}{\mathrm{C}}=\mathrm{O}\ldots\\ \updownarrow\\ \text{—}\mathrm{H}\ldots\mathrm{O}=\overset{|}{\mathrm{C}}\text{—}\mathrm{O}\text{—}\mathrm{H}\ldots\mathrm{O}=\overset{|}{\mathrm{C}}\text{—}\mathrm{O}\text{—}\mathrm{H}\ldots\mathrm{O}=\overset{|}{\mathrm{C}}\text{—}\mathrm{O}\text{—}\end{array}$$

In proteins, the chief forces (other than those in the crystine and similar cross links) connecting the primary chains I believe to be due to hydrogen bridges. Both the so-called 'salt linkages' and the frequently assumed attractions between CO and NH groups may reasonably be assumed to be of this character. A reasonable structure for β keratin[1,7], for example, is one involving synchronized hydrogen and electron oscillations along..HNCOHNCOHNCO..strings comparable to the..HOCOHOCOHOCO.. strings in oxalic acid. With other proteins (and with keratin in less extended form) structures differing in detail must be assumed, but in all, I firmly believe, NHO bridges are most important in joining the primary chains. Pictures of this sort seem to me preferable to those proposed by Wrinch[8].

Effect of Turbulence on the Propagation of Sound

IT is a well-known fact that the propagation of sound in the atmosphere is greatly affected by temperature and wind conditions, yet quantitative data on the actual field of intensity from a sound transmitter are scarce. During some recent studies of the acoustical effect of fog-horns, we determined the attenuation of the sound at the sea surface[1]. A condenser microphone was used at intensities greater than 40 decibels and an auditory comparison method was used at lower intensities. Intensity charts are reproduced herewith (Fig. 1) for two succeeding days on which there were weak winds and apparently homogeneous atmospheric conditions. The two charts show clearly the effect of differing wind direction, but other differences between them are also obvious. On December 13 (B, Fig. 1) the air probably was stratified either with respect to velocity or to temperature, since the intensity chart shows a marked minimum to the north-west.

Independently of these differences in the average field on the two days, our instruments showed rapid variations in the observed intensity. These were not discovered by the ear, the sensitivity of which to intensity differences is rather low for the frequency applied, 300 c./s. Within one sending period of the transmitter, namely, 3 seconds, the variations of energy at the place of observation were often 5–10 decibels (special measurements showed that these variations were not due to fluctuations of the transmitter). We must thus imagine that the surfaces of equal intensity were rapidly changing in a most irregular way, giving an average picture as represented above.

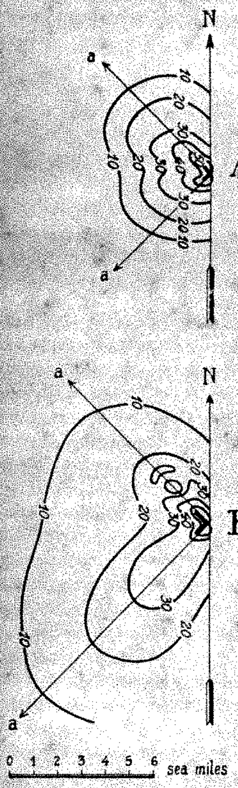

Fig. 1.

FIELD OF INTENSITY (IN PHONS) AT THE SEA SURFACE OF A DOUBLE SOUND TRANSMITTER. *a,a*, AXIS OF HORN. *A*. DECEMBER 12, 1935. WIND S.S.E.; BEAUFORT 2–3. *B*. DECEMBER 13, 1935. CALM OR WIND BETWEEN N.N.E. AND N.; BEAUFORT 1–2.

As already pointed out by Devik[1], the *turbulence* of the air is probably the cause of these great variations. We do not here refer to the molecular dispersion of sound (compare V. O. Knudsen[2]) but rather to the irregular distribution of rolling and whirling 'air bodies' of a great variety of sizes, which we assume will cause a dissipation of sound energy especially pronounced for those wave-lengths which are of the same order of size as the 'air bodies' themselves. If this be the case, the study of the attenuation of a sound spectrum in open air might furnish a method for studying the turbulence of the air. Experimental research in this direction is being prepared here.

Raman Effect as a Method of Analysis of Amino Acid Solutions

THE possibility of using the Raman effect for quantitative analysis depends upon two conditions: (1) The components of the mixture in question should possess distinguishable spectra, a requirement depending on the nature of the molecules. (2) The photographed spectra should be sufficiently intense and the background clear enough to provide good microphotometer measurements. The accompanying account concerns an investigation of these conditions in the case of amino acid solutions.

The experimental arrangement was similar to that used by Wood[1], employing a 600-watt, air-cooled, quartz mercury arc. Because the solutions of recrystallized amino acids often exhibited fluorescence (due to minute amounts of impurities) when exposed to the blue light of the arc (4358 A.), it appeared advisable in the present case to adopt the green line (Hg 5461 A.) for the Raman excitation. A further reduction of fluorescence was effected by treating the neutral solutions with a small amount of potassium iodide. Two filter solutions, one of dilute potassium dichromate and the other of saturated neodymium chloride, served respectively to remove the blue end of the mercury spectrum and to absorb the region from 5680 A. to 5910 A. The spectrograph was a two-prism instrument providing a dispersion of 64 A./mm. in the yellow; exposure times varied from ten to thirty hours.

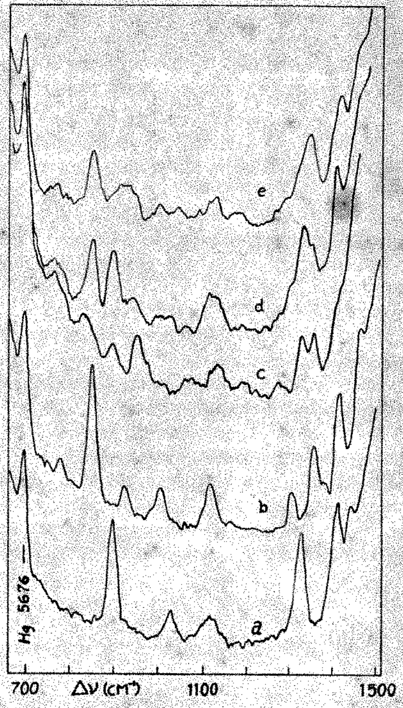

Fig. 1.

According to previous measurements by us on the Raman effect of several amino acids[2], the region corresponding to displacements of 700–1500 cm.$^{-1}$ (interval cleared of light from the arc by the neodymium chloride band in the present arrangement) was well adapted for the purpose at hand. Additional measurements of Raman frequencies made since the earlier publication are listed below: *dl*-Valine (aqueous solution, 5 per cent, 20 per cent potassium iodide): 760 cm.$^{-1}$ (6), 828 (6), 893 (4), 945 (8), 1063 (3), 1130 (4), 1196 (3), 1276 (2), 1326 (10), 1360 (9), 1410 (8). *l*-Leucine (aqueous, 1·55 per cent, 20 per cent potassium iodide): 840 (10), 964 (10), 1060 (2), 1135 (5), 1175 (2), 1351 (10), 1412 (2). *dl*-Phenylalanine (aqueous, 2 per cent, 20 per cent potassium iodide): 432 (1), 487 (1), 622 (3), 755 (1), 824 (2), 925 (1), 1003 (10), 1032 (4), 1211 (4*b*), 1270 (1), 1349 (2*b*).

Microphotometer records are shown in Fig. 1 of the Raman spectra of 5 per cent aqueous solutions of glycine (*a*), *dl*-alanine (*b*), *dl*-valine (*c*), and a mixed solution of 5 per cent each of the three (*d*). The spectrum (*e*) is that of a zein hydrolysate from which the less soluble amino acids have been partially removed by crystallization. These curves reveal the situation as regards analysis very clearly. With no more than three of the simpler amino acids together in a solution, overlapping of the lines most suitable for measurement can be observed. As most protein hydrolysates are vastly more complicated than this simple case, it would seem undesirable to attack such solutions without further chemical separation. If cases should arise, however, where solutions under examination contain very few different amino acids, the Raman effect might indeed be of great value in analysis.

Research on Biological Control

REFERENCE is made in an article in NATURE of February 20, on inter-Imperial co-operation in scientific research, to the recommendation of the British Commonwealth Scientific Conference concerning Farnham House Laboratory, and to the fact that, though this method of controlling insect and plant pests is in its infancy, no reference is made to the need of research into it.

We at the Laboratory have clearly recognized the necessity for this fundamental research, without which practical work in biological control can never emerge from its present empirical status, and have been seeking, ever since the Laboratory was founded, to find some way of putting its research activities on a reasonably sure and lasting foundation. In 1929 the Empire Marketing Board, which provided the initial capital and maintenance grants, agreed to make an additional maintenance allotment, on the understanding that this should be used, so far as possible, for the development of research into fundamental problems; but the severe economies necessitated by the financial crisis in 1931 obliged us to recast our programme, and since that time we have been unable to make any definite provision for research. It was hoped that the Scientific Conference would make the necessary recommendations, as the desirability of this was mentioned in the report of the Laboratory for 1935–36[1], and had been previously stressed by the Imperial Entomological Conference[2].

Since official support for research work has not been forthcoming, and the necessity for fundamental studies is increasing because of the rapid growth in the practical side of the work, the only possible course seems to be to appeal to individual workers interested in research on biological control, to avail themselves of the facilities offered by the Laboratory for investigations of this kind. The accommodation is limited; but it will be gladly put at the disposal of students and others qualified for the work. The main lines of research requiring development concern parasite behaviour, population studies, from the biomathematical angle, particularly the interactions between host and parasite populations, and genetic studies, for which large masses of material collected under a considerable range of environmental conditions, are readily available. Abundant material for cognate studies in the development and morphology of insect parasites is continually coming in. There is thus an opportunity for the pursuit of many fascinating lines of investigation of great scientific and practical value.

I shall be glad to answer any written inquiries with regard to the work.

Base Exchange Capacity and Clay Content of Soils

VARYING factors have been reported for the base exchange capacity of soil clays. Mattson[1] gave results ranging from 0·16 to 1·1 milligram equivalents (m.e.) per gram. Williams[2] uses the value 0·57 for the evaluation of the exchange capacity of a soil from its clay and carbon contents. Hissink[3] found values between 0·36 and 1·00 for Dutch soils.

In general, 0·5–1·0 m.e. per gram has been accepted as the range to be expected for the base exchange capacity of mineral soil colloids. It is to be noted, however, that these values are dependent on the definition of particle size, such as less than 2 μ. Even if this upper limit can be accepted, the exchange capacity must depend on the relative particle distribution. Mattson's[1] and other data have shown the importance of chemical composition, in particular the $SiO_2 : R_2O_3$ ratio, in determining adsorption capacity.

The investigation of the base status of soil profiles on basic igneous parent materials has disclosed that some lower horizons, free from organic matter, have a base exchange capacity of up to 9 m.e. per gram of (< 2 μ) clay. The accompanying table shows some of the results obtained:

Soil	SiO_4/Al_2O_3	Clay Content	Exchange Capacity	m.e. per gm. Clay
4792	1·55	16·0	35·2 (32·9)	2·2
5048	3·83	11·6	42·5 (43·0)	3·7
5044	4·05	10·7	41·8 (39·0)	3·9
4784	5·95	9·8	42·1 (38·9)	4·3
5001A	8·40	15·7	88·0 (98·6)	5·6
5002	2·16	3·8	34·8 (29·6)	9·1

The exchange capacity figures used were obtained by the Parker method[4]. Those in brackets are the sums of the individual exchangeable cations. The agreement between the two sets of figures demonstrates the truly exchangeable nature of the cations. Apart from the last sample, there is an approximately linear relationship between SiO_2/Al_2O_3 ratio and exchange capacity per gram (< 2 μ) clay.

Further work is at present in progress on these soils, and the results obtained will be reported elsewhere. We desire, however, to point out that soils with very high exchange powers relative to their clay contents exist, and to direct attention to the danger of indiscriminate application of clay exchange capacity factors to soils to which they do not apply.

Absorption of Fumigants under Reduced Pressure

THE importance of absorption of gases in reducing the effective concentration during fumigation of various materials for the destruction of insects, is now coming to be recognized, but the full effect of this factor in so-called 'vacuum fumigation' does not appear to have been realized.

Some preliminary experiments with a patent flour indicate that, if the bulk of the air be first removed, then most of the gas, which penetrates by virtue of the pressure difference established on admitting the fumigant, is rapidly absorbed, leaving, in the interior of the material, a very low concentration, which may not be effective in killing the insects. Afterwards the concentration in the middle of the material increases slightly owing to the diffusion, as in a fumigation at ordinary pressure. This is true whether the pressure is brought up to atmospheric by employing a fumigant diluted with an inert gas, or whether the pressure is raised only by the amount due to the pure or slightly diluted fumigant.

The result appears to be that the fumigation of absorbent materials under reduced pressure possesses little advantage over fumigation at normal pressure. This work is being continued and we hope to publish a detailed account in due course.

Points from Foregoing Letters

COLONEL S. P. JAMES and Dr. P. Tate have found that the life-history of the malaria parasite *Plasmodium gallinaceum*, Brumpt, comprises, in addition to the usual schizogonic cycle of development in the red blood corpuscles of its vertebrate host and the usual sporogonic cycle in its insect host, a hitherto unrecognized vertebrate cycle occurring in cells of the reticulo-endothelial system of the spleen, liver and other internal organs and particularly, in certain cases, in the cells which line the capillaries of the brain. The finding of this endothelial cell cycle, whether or not it occurs in other malaria parasites than those of birds, opens up an entirely new field for chemotherapeutic research and may help to explain some of the clinical, therapeutic and epidemiological problems of malaria which hitherto have remained unsolved.

The usefulness of the Toepler *Schlieren* method for sedimentation observation in the ultra-centrifuge has been demonstrated by A. Tiselius, K. O. Pedersen and Inga-Britta Eriksson-Quensel. The method has the advantage of allowing direct observations, during the experiment, of the number of components in a mixture and their sedimentation velocities.

A method of obtaining liquid crystalline preparations of cucumber viruses is described by F. C. Bawden and N. W. Pirie. The authors compare some of the properties of these viruses (precipitation point in acid and salt solutions, etc.) with those of the tobacco mosaic viruses. The purified cucumber viruses can infect cucumber plants in dilutions of one part in a thousand million, and one eighth of a millionth of a gram will give a specific precipitate with antiserum.

A method of eliminating possible impurities in the electrodes used for spectrographic detection of plant constituents is described by W. A. Roach. It consists in preparing small electrodes from the plant material itself by suitable treatment and carbonization.

Reactions between nitric oxide and hæmoglobin, and also methæmoglobin, are described by Prof. D. Keilin and D. F. Hartree, indicating that a very stable compound is formed with hæmoglobin and an easily reversible one with methæmoglobin.

Drs. M. Dixon and C. Lutwak-Mann describe results showing that aldehyde mutase and aldehyde oxidase, hitherto believed to be identical, are in reality distinct enzymes. They can be prepared separately, and they show fundamental differences in behaviour.

The use of Chlorazol Black E as a biological stain for general purposes is described by Prof. H. Graham Cannon. It requires no mordant and no differentiation.

The ramming of a whale shark by a steamer near Colombo is described by Dr. E. W. Gudger, who discusses the occurrence of this fish in Ceylonese waters.

Dr. M. L. Huggins points out that hydrogen bridges, which recent work has shown to be of great importance in many chemical and biological fields, are more stable than they would otherwise be if the oscillation of the hydrogen is accompanied by a synchronous oscillation of the electron system in a ring of which the bridge forms a part. Two hydrogen bridges in the same ring tend to oscillate together, each stabilizing the other. Synchronous oscillation of bridging hydrogens suitably connected together in long strings also increases the stability.

Microphotometer records of the Raman spectra of solutions of several amino acids (glycine, *dl*-alanine, *dl*-valine) separately and mixed are submitted by N. Wright and W. C. Lee, and compared with a similar record of a zein hydrolysate, from which the less soluble amino acids had been partially removed. It appears that the Raman effect might be used for quantitative analysis of proteins in solutions containing very few different amino acids, but that it is not applicable to more complex mixtures.

Quantitative measurements by H. Dahl and Dr. Olaf Devik of the intensity of the sound field of fog-horns has shown rapid variations which were not observed by the ear. The cause of these rapid variations is considered to be the turbulence of the air. If this is the case, the study of the attenuation of a sound spectrum in the open air might furnish a method for studying the turbulence of the air.

Dr. R. L. Mitchell and Dr. Alex. Muir direct attention to the high base exchange capacity relative to the clay content of certain soils derived from basic igneous parent materials in Scotland.

A preliminary study of the concentration of gas inside certain materials fumigated by various methods employing reduced pressure shows, according to Drs. A. B. P. Page and O. F. Lubatti, that owing to absorption there is no resultant increase of penetration. It appears that, with these materials, a vacuum process has no advantage over one at normal pressure.

Research Items

Early Contacts of East and West

Prof. C. G. Seligman in his Lloyd-Roberts Lecture for 1935, delivered before the Royal College of Physicians, on "The Roman Orient and the Far East" (*Antiquity*, March) dealt mainly with historic contacts extending over something more than a thousand years, from 200 B.C. to A.D. 900, touching in the prehistoric period only on the distribution of the socketed celt, one of the most characteristic implements of the Late Bronze Age in central and eastern Europe, which probably reached China five to six hundred years before Christ. Its presence may be associated with events in the far north-west which started the movements of the Scyths. It was borne eastward on a wide front across the Urals. In the historic period, the great silk route, five thousand miles long, joined the Far East with Antioch, the most important city of the Roman Orient. It was first organized in the second century B.C., though long before this lapiz lazuli had reached Ur and pre-dynastic Egypt (that is, 3000 B.C. and earlier). The eastern section of the route may be regarded as starting at Ch'ang An (the Han capital), or at Lang-chow in western Kansu. It crosses Sinkiang to Kashgar, 1,500 miles away, Turfan lying half-way. The middle section crosses the Pamirs to Merv, either by Samarkand or Balkh. From Merv it runs west and south across north Iran to Seleucia-Ctesiphon, just below the modern Bagdad, crosses the Euphrates at Zeugma, and so thence to Antioch. The factors tending to the use of the silk route in the first instance were neither commercial, desire for knowledge nor love of conquest, but sheer military necessity—to counter the attacks of the barbarians. But there was also the desire for a supply of fine horses from Iran, while another gift from Ferghana was the grape for wine. From east to west the road essentially carried silk and secondarily furs. In addition to gold the Roman Orient exported glass. In the great period of the T'ang dynasty (A.D. 621–907) the silk route attained its maximum importance ; and while China shows the effect of the impact of western art and art forms, as well as of legend and story, it gave to the west paper and printing.

Mammals of Oregon

The State of Oregon illustrates in general the history of any mammalian fauna under the rule of civilized man. The quest of valuable furs brought pioneers into the region, and the abundance of game is still an economic factor of some importance. As man and domestic animals increased, animals destructive to game, livestock, poultry and crops had to be destroyed or controlled, with the result that predatory animals are reported to be generally decreasing in abundance, while a few creatures such as wapiti and other deer, pronghorn antelopes and porcupines are said to be increasing in numbers. In his account of the "Mammals of Oregon" (*North American Fauna*, No. 55. U.S. Dept. Agr. Pp. 416), Vernon Bailey discusses with a large amount of detail the economic as well as the natural history and taxonomic aspects of a fauna which includes 246 species and races. Oregon shows great diversity of altitude and of climate, and the consequent zonal distribution of its vertebrates and its plants throughout five of the seven primary life zones of the American continent (tabulated on pp. 31–53) contains much that is of ecological interest. We note that the author does not fear any undue spread of the musk-rat, for although he admits that it is capable of doing serious damage in irrigated areas, he holds that more thorough trapping and a long open season usually afford all the protection necessary.

Digestion in Metazoa

The problem of the modes of digestion adopted by the Metazoa has been reviewed by Prof. C. M. Yonge (*Biol. Rev.*, Jan. 1937). In Protozoa and Porifera, digestion is obviously intracellular, and this method is retained to a certain extent in different groups of the Metazoa. Extracellular digestion is found to a greater or lesser extent in all of them. This method is obviously advantageous since it allows food to be digested and the non-utilizable material to be removed more quickly, thus permitting an increase in the rate of metabolism. It is also associated with a differentiation in certain regions of the gut and so produces more efficient mechanisms for dealing with the various processes involved in ingestion, digestion, absorption and the formation of fæces. Some groups have acquired enzymes which enable them to deal with special substances. In general, the food passes through the alimentary canal at such a rate as will enable it to be adequately digested, taking into consideration the temperature, *p*H and enzymes. Such specialization has enabled the successful groups to utilize a wider range of food-stuffs and to tap more varied sources of supply. A full bibliography is appended.

Sites for Anemographs

An account of the peculiar performance of a Dines anemograph at the Lizard (Prof. Note No. 73, Meteorological Office, Air Ministry, by M. J. Thomas. London : H.M. Stationery Office, 1936) shows the care that is required when selecting a site for an anemograph in order to get a representative record of the speed and direction of the wind. It was observed that with most winds the record showed the gustiness and variability of wind direction to be expected in a reasonably open situation, with the vane of the anemograph at a height of 40 feet above the ground, but that when the general wind in the neighbourhood was between about south-south-west and west-south-west the vane fluctuated wildly, and sometimes 'boxed the compass' at short intervals for hours. Inquiry was made into the cause, and it was found that violent eddies were being set up by a row of coastguards' houses about 30 feet high and more than 100 feet away in the direction from which the general wind was blowing during the most disturbed periods. These eddies were studied with the aid of ballons of zero lift, both free and tethered, and bamboo poles with long streamers, and the nature of the eddies was brought to light. The pamphlet shows their movement both in plan and elevation. The trouble was eventually cured by raising the vane of the anemograph to a height of 75 feet; that is, it was brought to a height of 45 feet above the houses instead of only 10 feet. After the change, normal gustiness and variation of direction was obtained, as is illustrated by the anemogram for several hours of a severe gale during which the average wind direction changed from south to nearly west.

Artificial Radioactivity Produced by Means of γ-Rays

ARTIFICIAL radioactivity has recently been produced in the elements copper, bromine and phosphorus by bombarding them with γ-rays obtained by the action of protons of energy greater than 450 kV. on lithium (W. Bothe and W. Gentner, *Naturwiss.*, **25**, 90; 1937). Observations of the half-life periods of the radioactive nuclei enables them to be identified. Copper gives a radioactive nucleus of half-life about 11 min. Heyn (NATURE, **138**, 723; 1936) obtained by another method, a half-life of 10·5 min. for the ^{62}Cu nucleus. It therefore seems likely that this is the nucleus formed in the present transmutation, and that the process involves loss of a neutron from ^{63}Cu. In the case of bromine, the radioactive nucleus had a half-life period of about 18 min., which is the same as that of ^{80}Br obtained by the action of slow neutrons on ^{79}Br. Phosphorus gives a radioactive nucleus of weak activity with a half-life period of 2–3 min. This is probably to be identified with ^{30}P, which has been obtained by other methods indicating for it a half-life of 3·2 min. As with copper, the radioactive nuclei obtained from bromine and phosphorus are produced by the loss of a neutron from the normal nuclei.

Long Wave Spectroscopy of Benzene

SPECTROSCOPIC investigation of C_6H_6 and C_6D_6 by Angus, Bailey, Ingold, *et alia* (*J. Chem. Soc.*, 912; 1936) pointed with considerable certainty to a molecular symmetry of D_{6h}, and this has recently been substantiated by the thermal-spectroscopic determination of the symmetry number by Lord and Andrews (*J. Chem. Phys.*, **41**, 149; 1937). But definite conclusions must await further experimental evidence on (*a*) the spectra of partly-deuterated benzenes of lower symmetry, and (*b*) the influence of temperature and change of physical state on the characteristics of the spectrum. Evidence on both these lines is forthcoming. Redlich has already published some interesting measurements on partly deuterated benzenes. Along the other line, the results of Sirkar (NATURE, **134**, 850; 1934; *Indian J. Phys.*, **10**, 189; 1936) are particularly interesting. From an examination of the Raman spectrum of C_6H_6 vapour at 210° C. and 16·6 atmospheres, he has shown that the intensity distribution of the rotational wings accompanying Rayleigh lines agrees with that predicted from the theory of rotational Raman scattering. In the later paper, he has given results for the temperature range from liquid air temperature to 210° C. and for solid, liquid and gaseous C_6H_6. At low temperatures he found a slight diminution in the numerical values of frequency displacements and an increased sharpness and intensity, in agreement with the earlier observations of Epstein and Steiner (NATURE, **133**, 910; 1934). By comparing the spectra of liquid and gaseous C_6H_6 at 210° C., he has shown that the numerical values of displacements are unchanged, but transition from liquid to vapour is accompanied by greatly diminished intensity. A similar comparison by Bhagavantam and Rao (NATURE, **139**, 114; 1937) leads to the same result. Knowledge of these variations will help to elucidate the part played by intermolecular forces, and will assist in explaining the apparent breakdown of selection rules when applied to experimental data.

Diamantine Compounds

IN the February issue of the *Berichte der deutschen chemischen Gesellschaft*, Dr. Oskar Böttger describes the synthesis of several complex cyclic compounds in which carbon atoms are linked together rigidly but without strain in the manner of the crystal lattice of the diamond. The parent hydrocarbon of such a series is still unknown, but as several of its derivatives have now been synthesized it is proposed to call it *diamantane*. Its highly symmetrical structure would result from the condensation into a three-dimensional network of four puckered cyclohexane rings of the *Z* variety, and its formula would be $C_{10}H_{16}$. By the action of methylene dibromide on the disodium derivative of bicyclo [1 : 3 : 3] nonane 2·6-dione 1·3·5·7 tetramethylcarboxylate, it was possible to synthesize a compound which possesses the same skeletal structure as diamantane and crystallizes in fine colourless octahedra, melting at 284° C. Hydrolysis of this ester to the corresponding tetrabasic acid was readily effected by dilute acids, whereas alkaline hydrolysis broke down one of the rings to yield a pentacarboxylic acid derivative of bicyclononanone, which could be extracted in the form of its methyl ester. The freedom from ring-strain of the polycyclic system can be inferred from the ease with which this pentamethyl ester reverts to the diamantine structure by eliminating methanol, when it is heated above 200° C. On the other hand, this structure appears to influence the chemical properties of its substituent groups, since the acid groups did not yield to the usual methods of decarboxylation, nor was it possible to reduce the two keto-groups to methylene groups, for even hydrogen iodide and phosphorus under pressure yielded only secondary alcohols. The optical isomerism of the products has not yet been investigated.

Scope and Development of Indian Astronomy

IN an article in *Osiris* of September 1936, Sukumar Ranjan Das says that Indian astronomy had its beginning in the Vedas, and was then very rudimentary. This is incorrect; the ancestors of the Vedic authors brought their astronomy with them when they came to India, and these astronomical conditions are both extensive and well founded, and were quoted throughout the much later Rg Veda and the liturgical Vedas and Brahmanas. The author has happily cut himself free, however, from the current idea that Indian astronomy was ever dependent on the Grecian or Ptolemaic systems; indeed India gave more than it ever got, except perhaps as regards planetary observations. Ranjan Das suggests that the Rg Veda has three allusions to the planets, but the contexts forbid this interpretation. The most interesting section is on the Samhitâs and older Siddhântas (dating between 500 B.C. and 500 A.D.). He gives a tantalizing reference to an observation in 215 B.C. of "the Sun and Moon in conjunction at sunrise *on a Sunday*" at the winter solstice, or the beginning of the solar month Māgha. Was time at that date divided into 7-day weeks for purposes of chronology, similar to our division of the Julian days? It certainly was so divided in the days of Āryabhata I, in the fifth century A.D.

The South-East Essex Technical College

THE construction of new arterial roads together with the development of estates like those of Becontree and Dagenham have resulted, within the last ten years, in a considerable increase in the population of Essex. The establishment, too, of large industrial centres, such as Ford's Motor Works at Dagenham, have also contributed materially to this almost mushroom growth. Acres of pasture land have thus been transformed into industrial and densely populated districts. It therefore became an urgent necessity to make some provision for extended educational facilities, and especially for further technical education.

After an exhaustive survey of the problem, the Essex Education Committee wisely decided that a regional system of organization for higher education generally would be, at present, the best solution. To carry this policy into practical effect, each region is to be provided with a central institution "to act as a focus of the more advanced forms of technical, art and commercial instruction". The first of these institutions—known as the South-East Essex Technical College—was officially opened by the Right Hon. Oliver Stanley, president of the Board of Education, on Tuesday, November 24, 1936, although some four thousand students had already started courses of instruction on September 28, 1936.

Through the courtesy of the Director of Education (Mr. J. Sargent) and the Principal (Mr. P. J. Haler), a recent tour of the college revealed the high practical ideal with which the Committee determined to give effect to its considered policy. Here is a veritable palace of learning, stated to be the largest of its kind in Great Britain. Along the Longbridge Road, about two miles from Barking Station and close to the south-eastern boundary of the Borough of Ilford, a stretch of land, about 17 acres in extent, was secured and upon approximately 6 acres the college building was erected (Fig. 1). Although the premises are really not yet complete, accommodation is to be provided for about 5,000 evening students and 1,000 full-time day scholars from eleven to sixteen years of age and 750 senior students. To meet the needs of the essential recreative facilities for so large a number, the Committee is trying to secure more land in order to extend the acreage to about 30. It also proposes, in the near future, to provide a swimming bath, two gymnasia, a sports' pavilion and other adequate accommodation. Indeed, in giving practical effect to its policy, the education authority has not confined itself merely to existing needs, but also has designed the various blocks of buildings "with reference as much to the future developments of the college as to its present requirements".

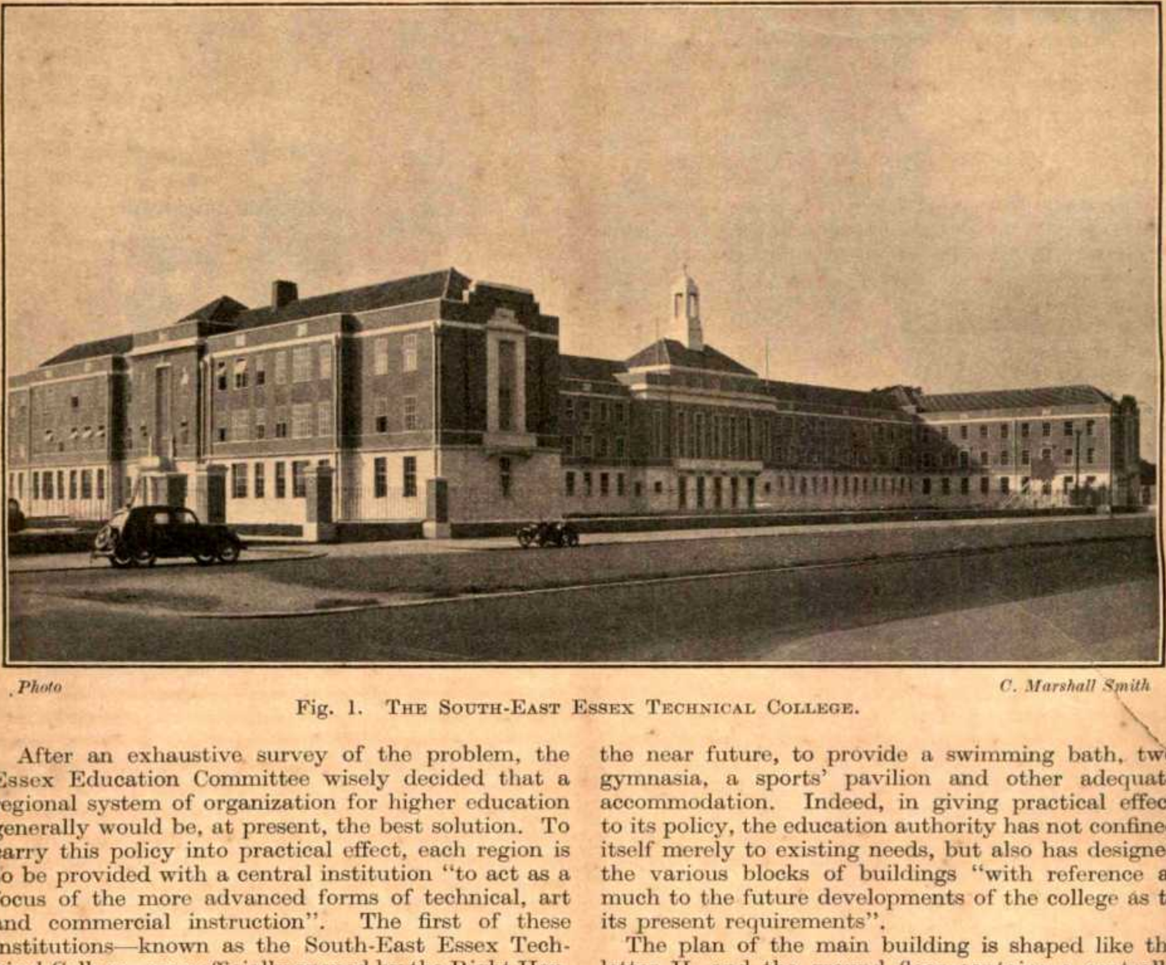

Photo *C. Marshall Smith*

Fig. 1. THE SOUTH-EAST ESSEX TECHNICAL COLLEGE.

The plan of the main building is shaped like the letter H, and the ground floor contains a centrally placed assembly hall to seat 1,000, with a stage for dramatic performances at the west end and a projector room at the back of the balcony at the east end. The acoustics of this hall have been very skilfully considered. On the other side of the central corridor or foyer are the exhibition hall and the administrative offices. Both the ground and first floors of the east wing are devoted to the department of domestic science, whilst the art department occupies the second floor. The west wing provides accommodation on the first two floors for the commercial department where the latest contrivances for mechanizing arithmetic may be seen. On the central portion of the first floor—reached either by stairs or lift—are the library, board room, Retail Trades and Commodities Room. Between the upper part of the assembly hall and the library is a wide corridor lined with many fine pictures. In fact, the portion directly over the foyer is called the Picture Gallery. Directly above the assembly hall on the second floor is the cafeteria and dining hall fitted with a complete kitchen unit.

Behind the main building and connected by covered corridors are the departments of science and engineering, with a car park between them. At present, these are on the ground floor, but the science block will eventually be enlarged by the addition of two more floors. It now comprises laboratories for biology, building science, chemistry and physics, all equipped with the most modern appliances. It is anticipated to develop specialized courses with particular reference to the needs of local industries, for in the neighbourhood there are several large manufacturing chemists, an important cement works and one of the largest factories in the country for the production of photographic materials. Co-operation with some of these has already been established.

In the engineering block are to be found workshops for carpentry, automobile construction, plumbing, electrical installation and machine tools, each of which is thoroughly equipped with the latest machinery, all unit driven. There are also a spacious drawing office and an applied mechanics laboratory. As in the case of the science department, it is hoped to correlate the work done with local industries, and already the Ford Motor Company is sending a large number of employees to the college for instruction.

Here, indeed, is a worthy institution wherein to "find out what a man can do and then teach him to do it better". F. G. W. B.

Excavations at Chandhu-Daro, Sind

CHANDHU-DARO, a mound site near Sukhpur in the Nawabshah District of Sind, was selected for investigation by the American School of Indic and Iranian Studies, with the active support of the Boston Museum of Fine Arts, in the hope that it would afford evidence bearing on the beginnings of the Harappa civilization, as known from the sites of Mohenjo-daro and Harappa in the Indus valley, or alternatively on the dark period between the disappearance of that civilization and the entry into India of the Aryan-speaking peoples at about 1500 B.C. The excavations have been conducted by Dr. E. J. A. Mackay, who described their progress to date before the Royal Society of Arts at a meeting on March 5.

The site of Chandhu-daro, situated east of the River Indus and eighty miles south-west of Mohenjo-daro, consists of a complex of two large mounds and one small mound. In ancient times they constituted a single city, which was cut right through by flood water of the Indus, a disaster which led to the city being abandoned. There is indisputable evidence that a similar disaster occurred on more than one occasion and as Mohenjo-daro also suffered similarly from flood on at least two occasions, it is now thought probable that the decline of this great civilization may have been due to the impossibility of occupying sites that were continually being surrounded by large sheets of water.

Although the city in size never approached that of Mohenjo-daro, a massive wall, averaging five feet wide and traced for eighty feet, which was among the earliest discoveries, suggests that the city was of considerable importance.

In order to ascertain whether the site had been occupied by any peoples earlier than those of the Harappa culture, Mound II was examined to its lowest levels by a pit which was taken down to water-level. It then appeared that some five thousand years ago Mounds I and II had constituted a single city, as already mentioned. In this part of the site, at least, no culture lay between subsoil water, which was reached at twenty-five feet below plain level, and the mound above. The lowest levels at Chandhu give the impression of being earlier than the strata immediately above water-level at Mohenjo-daro.

There are no less than five Harappa occupations. They were separated by layers of debris, and there could be no doubt, as there is at Mohenjo-daro, as to where one occupation ended and another began. Whether there are other occupations below water-level, it is impossible to say. The water-level has risen considerably. Of the five levels, the two uppermost on Mound II only have as yet been cleared, and the three lower are still to be examined. In the earlier of the upper Harappa levels the most striking feature is the existence of a bathroom in practically every house and the elaborate and careful system of drainage. There can be little doubt that bathing must have been a ritual. Where smaller and less important houses were not connected with street drainage, a system of cesspits or storage vessels was employed. In the main street of the second Harappa level a remarkable building was unearthed, which seems to have been some kind of a Turkish bath, with small chambers situated over flue holes. There is no other evidence that the ancient peoples of India used hot-air baths, but a somewhat similar building was discovered at Mohenjo-daro.

The buildings of the last Harappa occupation were the better preserved, but the area of occupation was very much less. Not long after the site had been abandoned, it was occupied again about 2000 B.C. by a small community of unknown origin, the Jhukar, living in houses of matting or mud. Of these dwellings all traces have disappeared, except the remains of the floors and the fireplaces, which were practically unknown among the Harappa people, who used open hearths.

After the disappearance of the Jhukars, Mound II was occupied once more by a small community, who used hand-made, polished, grey ware already known as the Jhangar culture from the site of that name in Sind.

The pottery from Chandhu-daro is perhaps the most interesting that has been found on any ancient site in recent years. The painted ware is quite distinctive, and can be confused with no other ware. Unfortunately, few jars have been found complete. As on a similar ware at Mohenjo-daro, the motifs are painted in a thick black paint on a highly burnished red slip, which is almost like lacquer. Among the motifs is a quadruped with an exaggerated plume-like tail, a peacock with a crest of bush or tree-like form, while another bird has a crest which terminates in two sun-motifs. The sun apparently is conceived as a rotating sphere with prominences, while the association of the sun with vegetation is indicated by plant or bud designs, which represent these solar prominences. The larger storage vessels are frequently decorated around the upper part only. Incised decoration of pottery is comparatively rare.

The pottery of the Jhukar people in fabric, mode of decoration and polychrome colouring is quite different from that of their predecessors. Violet-black paint was applied to a thick cream slip. Below the decorative border are bands of red paint. Nor have the shapes any relation to the earlier wares. A clue to origin is afforded by a herring-bone pattern painted alternately in red and black, which recalls the much earlier ornamentation on wares from Tell Halaf in Mesopotamia and that found by Sir Aurel Stein at Zayak in southern Baluchistan. One triple vessel of the Jhangar grey ware also recalls a find made by Sir Aurel Stein at Shahi-tump in Baluchistan. This suggests that these people too may have entered India from the west, and possibly at a much earlier date than has been thought.

The seals used by the Harappa people are like those found at Mohenjo-daro; but those of the Jhukar are more primitive, and for the most part made of pottery. In the Harappa period, Chandhu-daro was a great centre of bead making, and beads have been found in all stages from the raw material to the finished bead. Among them were the cornelian beads ornamented with designs in white, such as have been found in Sumer, but now known to have been manufactured in India or by Indians.

Metal working in copper and bronze was a craft that was largely practised. Heavy blade axes, a scoop, new to the ancient world, knives, daggers, razors in three shapes, and hairpins all show great experience in metal working.

A large number of toys of various kinds were found, and nearly every child must have had a toy cart, usually made in pottery and closely following the real cart in detail. Pottery rattles, owing to their substantial make, are rarely found broken. Of objects connected with religion, the most interesting are the figurines of the mother goddess, which are very different from the cult images of the goddess found at Mohenjo-daro. They were without legs, but had a hollow base to stand on. Like other figures of the Harappa culture, they were richly loaded with jewellery and their ears were pierced for ear-rings. Little jewellery was found.

Although the unique objects found on the site naturally have remained in India, the Archæological Survey has been generous in the allocation of objects to the Boston Fine Arts Museum. This is the only collection of objects illustrative of the early Indian civilization on exhibition outside India, and it is to be regretted that no similar collection is to be found in the museums of Great Britain. The exploration of the many sites of importance in India should not be left to other countries, and no British expedition organized to work in this most promising field.

Canadian Hydro-electric Power Development in 1936

ALTHOUGH the actual output of electricity in Canada during 1936 reached the new high level of 25,493½ million kilowatt-hours, the year was not specially remarkable for progress in development of the available water supplies. The annual review of hydro-electric power progress, issued by the Canadian Minister of Mines and Resources on January 1 of this year, shows that a comparatively small addition was made to the preceding year's aggregate of water-power developed in the Dominion, which at the end of 1935 had attained a figure of 7,909,115 horse-power. New installations during the twelve months increased this by 36,475 to the new total of 7,945,590. This is a little short of 8 millions, and, as the estimated total available is fully 40 millions, represents barely twenty per cent of the country's resources.

Notwithstanding the relatively small increment for the year, there is a number of projects actually under way which will add materially to the aggregate during the course of the next year or two. The progress of hydro-electric development in Canada within recent years has been largely influenced by the conditions arising out of a period of restricted output, lasting from 1930 until 1933. Prior to 1930, a number of important installations had been made in order to keep pace with a steadily growing demand for power which, however, slackened and ceased about six years ago. It was not until May 1933 that the demand resumed an upward tendency which has continued. But it produced a corresponding relaxation of effort in regard to new enterprises, the effect of which has not yet quite dissipated itself, though there is every likelihood of its doing so in the very near future.

The new installations during 1936 consisted chiefly of additions to existing stations at High Falls (a fourth unit of 30,000 horse-power), on the Lievre River in the Province of Quebec, by the Maclaren-Quebec Power Co.; at Rat Rapids (a new unit of 1,750 horse-power), on the Albany River in the Province of Ontario; and at Ruth Falls (4,300 horse-power) on East River Sheet Harbour, Nova Scotia. Several small installations have also been completed in British Columbia.

The Quebec Streams Commission has continued to maintain satisfactorily the desired regulation of flow on all the controlled rivers in the province by means of its extensive system of storage reservoirs, of which there are now seventeen, some of them of considerable size. It is actively pursuing investigations in regard to other available storage sites with the view of adapting them to the same purpose.

BRYSSON CUNNINGHAM.

Science News a Century Ago

Baron Antoine Dubois (1756–1837)

BARON ANTOINE DUBOIS, the celebrated French surgeon and obstetrician, whose death occurred on March 30, 1837, was born at Gramat, a small town in the Lot Department near Cahors, on July 17, 1756. After commencing his studies at Cahors, he went to Paris at the age of twenty years, where, like three other famous French surgeons, Ambroise Paré, J. L. Petit and Desault, he had at first a hard struggle with poverty until Desault made him his assistant. In 1790 he was elected member of the Paris Academy of Surgeons and in the following year Louis XVI made him professor of anatomy. Shortly afterwards, he joined the army and served first at the military hospital at Melun and then as member of the Army Health Council and inspector of the Army of the Eastern Pyrenees, and took part in Napoleon's Egyptian campaign. In 1811, when chief obstetrician to the Paris Maternity Hospital, he was summoned by Napoleon to attend the Empress Marie Louise during the birth of the subsequent King of Rome, and for his services on that occasion, when he successfully performed version, he was made a baron of the Empire. During the years 1830 and 1831 he was dean of the Medical Faculty of Paris.

Dubois was a clear and concise lecturer, an excellent teacher and an unrivalled operator. As a surgeon he is best known for his operations of lithotomy, aneurysm and anal fistula.

A National School of Mines

"Mr. John Taylor, well known as a lecturer on mineralogy, and great promoter of the search for subterranean riches, is at present actively engaged in endeavouring to found a national 'School of Mines', for giving instruction in all that relates to the theory, as well as the practice, of mining operations. Such institutions have long been in existence in Germany, where they have proved of great utility" (*Mechanics' Magazine*, April 1, 1837)

Watch Making at Geneva

"This manufacture commenced in 1587 and in 1600 the town council legislated upon it. In 1685 there were counted 100 masters and 300 journeymen watch makers at Geneva, who turned out by hand 5000 watches yearly. There were also 80 masters and 200 journeymen jewellers. The trade continued increasing till 1789 when it was at its height. In that year the number of those engaged in it in the city alone was 4000, and 2000 in the suburbs and villages. There are not now so many hands engaged, though more watches are made; the diminution of manual labour being occasioned by improved tools and machinery, and abridged mechanism of the watch. There has been a great falling off in this manufacture but very lately it has rather revived again" (*Mechanics' Magazine*, April 1, 1837).

European Medicine in the East

IN the issue of the *Quarterly Journal of the Calcutta Medical and Physical Society* of April 1, 1837, Dr. Henry Hurry Goodeve, editor of the journal and professor of anatomy and medicine at the Medical College, Calcutta, makes the following observations:

"Within the last twenty or fifteen years Anglo-Indian medicine has advanced with rapid strides. The immense improvements that have taken place in the medical science in Europe have doubtless contributed to this desirable end; for even in these distant regions we feel in our turn (though at times somewhat slowly) the influence of scientific studies at home. Thus following the track of our European brethren, we have pursued the never failing indications of pathology in the investigation of diseases; and aided by our knowledge of the true state of the affected organs, we have been able to employ with manifold advantage the improved modes of treatment which modern practice has brought into notice. Among these improvements one article of medicine deserves special attention. The discovery of Quinine has wrought a greater change in the treatment of disease than perhaps any other remedy which was ever introduced into the materia medica, not excepting its precursor and progenitor, the Peruvian bark. Nowhere has this change been so manifest as in India. In this country it has created a completely new epoch in the treatment of fevers of every kind, but most of all in those of the remittent class, in which it has almost brought back the old bark practice, although Quinine is administered in these maladies upon totally different principles from those which guided the exhibition of the cortex Peruvianii."

The Tread-wheel and Health

THE following extract from the second report of the Prison Inspectors of the Home District published on April 1, 1837, for presentation to both Houses of Parliament expresses the opinion of the governor of the Coldbath-fields House of Correction as to the effect of tread-wheel labour on the health of the prisoners:

"We had much sickness during the late epidemic, both among prisoners and officers, namely, the influenza in its various stages. Where prisoners are exposed greatly to the atmosphere and draughts, as is the case here on the wheels and in the passages, it must be injurious to health. Their coming off the wheels warm, for relief, and sitting in that state in the stages, must be bad. I think tread-wheel labour injurious to the health of some of the prisoners —to corpulent, or infirm and aged, or tall persons; but not to boys, lads, or men of light weight, if in good health. I take every possible means to prevent the bad effects of the tread-wheel by a judicious regulation of the labour, and by observing any ill-effects it may produce on the constitution of the prisoners; and if necessary immediately calling the attention of the surgeon to any cases of the kind, or by relieving them myself, according to circumstances in various ways; either by diminishing the labour, increasing the diet (often including porter), placing them to work in the grounds, etc. I find that the men in general are greatly distressed after three months' continuous labour, but tall and heavy men in a less time.

"With regard to women I believe tread-wheel labour, if judiciously used, is highly beneficial to health; particularly in cases of disorderly women, prostitutes, etc., committed for periods not exceeding three months, and who generally come into hospital in a deplorable condition from drink and intemperance, and quit it in good health. But these work less than the men, who labour in the proportion of twelve on the wheel to six at rest; the women in the proportion of twelve on the wheel to twelve off."

University Events

CAMBRIDGE.—At King's College, the following have been elected into fellowships: K. C. Dixon and D. G. Champernowne. Mr. Dixon was educated at Haileybury College. He was placed in the first class in both parts of the Natural Sciences Tripos and was awarded an additional Harold Fry studentship in 1934 and 1935. Mr. Champernowne was educated at Winchester College. He was placed in the first class in both parts of the Mathematical Tripos and in the Economics Tripos, Part II. He was elected Wrenbury scholar in 1935, and in 1936 was awarded the Adam Smith Prize.

At St. John's College a Research Studentship and Research Exhibitions are offered for competition in July. One Strathcona Research studentship of the annual value of £200 is offered for competition among research students who are (*a*) Graduates of any university other than Cambridge, or (*b*) graduates of Cambridge who are not already members of St. John's College. The successful candidate, if not already a member of the College, will be elected for two years, subject as regards a second year of tenure to his continuing in residence and to the College being satisfied with his progress; if he is already a member of the College, the tenure of the studentship will be for one year only. Two Strathcona exhibitions of the annual value of £40 are also offered for competition under the same conditions as the studentship. Further information can be obtained from the Senior Tutor, St. John's College, not later than July 1, 1937.

EDINBURGH.—The Senatus Academicus has resolved to offer the degree of LL.D. to the following among others: Prof. L. H. Baekeland, honorary professor of chemical engineering in Columbia University; Sir William Bragg, president of the Royal Society; Dr. Edwin Bramwell, a former president of the Royal Society of Physicians of Edinburgh; Dr. Alexander Morgan, formerly director of studies, Edinburgh Provincial Training College.

LEEDS.—Dr. J. B. Speakman, at present lecturer, has been appointed to a readership in textile chemistry, and Dr. W. T. Astbury, at present lecturer, to a readership in textile physics.

Prof. W. MacAdam, formerly professor of clinical medicine, has been elected to the chair of medicine in succession to Prof. G. W. Watson, and Prof. J. le F. C. Burrow, formerly professor of pharmacology and therapeutics, to the chair of clinical medicine. To the vacancy caused by these changes, the Council has elected Dr. S. J. Hartfall, with the title of professor of therapeutics and applied pharmacology.

LONDON.—Her Majesty the Queen has been graciously pleased to signify her consent to receiving an honorary degree from the University. The conferment of the degree will probably take place in the autumn.

Dr. H. L. Eason has been appointed principal of the University from July 1, 1937, until September 30, 1941 (see also p. 539 of this issue.)

Prof. Samuel Sugden has been appointed as from October 1 to the University chair of chemistry tenable at University College. Since 1928 he has been professor of physical chemistry in the University in respect of the post held by him at Birkbeck College.

The title of reader in mining geology in the University has been conferred on Dr. W. R. Jones (Imperial College—Royal School of Mines) and that of reader in palæontology in the University on Dr. W. F. Whittard (Imperial College of Science and Technology).

A further donation of £2,500 has been received towards the Institute of Archæology Appeal Fund from the same anonymous donor who had already contributed £12,500. Since the date of this last gift, the donor has died, and it can now be revealed that it was Mrs. Mary Woodgate Wharrie. Mrs. Wharrie was among the earliest and most generous benefactors of the recently established Institute of Archæology. Her gifts were the determining factor in the decision of the University to rehabilitate St. John's Lodge, Regent's Park, as the temporary home for the Institute and, in particular, for the display and utilization of the large collections of material excavated by Sir Flinders Petrie in Palestine and presented to the University by the British School of Archæology in Egypt. On the occasion of the opening of the Institute by the Chancellor of the University, it is proposed to dedicate the main gallery to Mrs. Wharrie's memory.

On the occasion of the meeting of the International Council of Scientific Unions in London in April an honorary degree will be conferred on Prof. N. E. Nörlund, the president of the International Council, and director of the Geodetic Institute of Copenhagen.

The degree of D.Sc. has been conferred on the following: Miss M. S. Lacey (bacteriology), B. D. Bolas (botany), Miss D. L. Reynolds (geology), A. K. Denisoff (physics), S. R. Rao (physics).

OXFORD.—Dr. J. A. Douglas, Keble College, lecturer in geology, has been elected professor of geology and fellow of University College.

SHEFFIELD.—The Rockefeller Foundation of New York has made a further grant of £250 in aid of research in the Department of Pharmacology of the University.

Societies and Academies

Edinburgh

Royal Society, March 1.

R. A. HOUSTOUN: The time lag of the vacuum photo-cell. The image of an electric filament was swept over the cathodes of two photo-cells, a *KMV*6 and a *KV*6, at various speeds, and the constancy of the photo-electric emission tested. Down to a duration of illumination of $7\cdot4 \times 10^{-8}$ sec. the law of proportionality held for the *KMV* 6, but there was a slight breakdown in the case of the *KV* 6. If this is ascribed to the presence of a time lag or period of induction, the latter will be about 5×10^{-10} second (see also NATURE, 139, 29, 330; 1937).

W. O. KERMACK and A. G. M'KENDRICK: Tests for randomness in a series of numerical observations. In a series of unequal numbers, some (maximal numbers) are greater, whilst others (minimal numbers) are smaller than either of their immediate neighbours. A sequence of runs extending from a maximal to an adjacent minimal number is called a 'run'. The average length of a run is 2·5, and the standard deviation is $\sqrt{3/5s}$, where s is the number (assumed large) of runs from which the average has been calculated. Other properties of randomly arranged numbers are also given. These results will probably be distributed by periodic or other regularities, and so afford tests of randomness.

A. C. Stephen: Production of large broods in certain lamellibranchs in relation to weather conditions. The fluctuations in the amounts of the broods of the littoral and sub-littoral species *Tellina tenuis* and *Tellina fabula* at Millport, Firth of Clyde, have been followed since 1926. There have been four specially large broods. Little or no correlation has been traced between these and the local sunshine and rainfall, but a very close connexion exists between the broods and temperature. The algebraic sum of the deviations of the monthly means from standard means has been used for comparison of temperature, sunshine and rainfall.

P. C. Koller: The genetical and mechanical properties of sex chromosomes. (3) Man. Two types of sex bivalent may be found at meiotic metaphase of man; one is asymmetrical and indicates the pre-reduction, the other is symmetrical and indicates the post-reduction of the structural inequality, which characterizes the sex chromosomes. The two types of sex bivalent suggest that the centromere lies in the pairing segment and crossing over may take place on both sides of the centromere. Genes which are localized in the pairing segment exhibit incomplete sex linkage. The occurrence of crossing-over in both arms of the pairing segment indicates that the total length of this region is more than 50 units, so that genes farthest from the differential segment should show very little sex linkage.

Vera Fretter: The structure and function of the alimentary canal of some species of *Polyplacophora* (Mollusca). The buccal cavity leads into the œsophagus, which expands laterally into a small pair of anterior pouches and receives the ducts of a pair of posterior pouches ('sugar glands') which secrete a diastatic enzyme. In the capacious stomach the food is mixed with a proteolytic enzyme secreted by the digestive gland. The soluble products of digestion are forced into the digestive gland from the anterior intestine by the action of an intestinal valve or sphincter. In the extensive coils of the posterior intestine the fæcal pellets are elaborated. Structurally the alimentary canal shows remarkable similarity to that of the lower Gastropods.

H. W. Turnbull: The revised complete system of a quadratic complex. A sequel to an earlier communication.

A. C. Aitken: Studies in practical mathematics. (1) The evaluation with applications, of a certain triple product matrix. In the solution of equations, the theory of correlation and in other parts of practical mathematics it is often necessary to obtain the reciprocal array of a given array of coefficients, and sometimes to transform the reciprocal array further by multiplying it before and after by other arrays. The paper describes a method, suited for practical use, by which such threefold product arrays may be evaluated by a uniform reduction. The method is exemplified in typical cases.

Rome

Royal National Academy of the Lincei

(*Atti*, 23, 807–911; 1936).

E. Bompiani: Normalization of linear differential equations.

G. Fano: Algebraic surfaces and varieties in three dimensions with canonical curve sections.

F. Severi: General theory of the correspondences between algebraic varieties (1).

G. Giorgi: The postulates of the second theory of relativity.

G. A. Blanc: Presence of *Equus hydruntinus* in the quaternary gravels of the Aniene.

A. Stella: Characteristics of the Italian metalliferous deposits in basic rocks.

C. Carbonaro: Completely derivable functions of one bidual variable.

S. Cherubino: Characteristic roots of holomorphous functions of matrices.

G. Bemporad: Development of the orbits of binary systems.

L. Gialanella: Meridian observations of Saturn, of Uranus, and of the moon in 1935.

G. Agamennone: Comparison of the epicentres of two recent similar earthquakes.

F. Odone: Absolute temperature *T* and the principal thermodynamic relationships.

A. Baroni: Chlorides of thiocyanogen.

S. Berlingozzi and G. Francini Naldi: Researches on rotatory amino acids.

V. Gaglioti and D. Gigante: Contribution to the biochemical knowledge of bones during development.

G. Centola: Relations between structure and mechanical properties of films and threads of acetylcellulose.

R. de Fazi and F. Pirrone: Chemical constitution of cholesterine (13). 13-18-Dimethyl-9-13-cyclopentane-5-6-dehydro-hydrophenanthrene-3 from cholesterine.

L. Mazza: Galvanometer amplification by means of differential photo-electric cells.

G. Tedeschi: Oxidation of monovalent nickel by the action of water in presence of CN^- ions.

R. Savelli: Observations on the chloroplasts of Cactaceæ.

G. Cotronei and T. Perri: Further researches on the embryonic compatibility and incompatibility in Amphibia studied by the method of grafting.

H. Grossfeld: Permeability of cell tissues cultivated *in vitro* (see also Nature, 138, 31; 1936).

A. Spirito: Studies of embryology (1). The phenomenon of anærobiosis studied comparatively in petromyzonts and in anuran amphibians.

(*Atti*, 23, 915–965; 1936).

G. Scorza: New contributions to the general theory of algebras.

F. Severi: General theory of the correspondences between algebraic varieties (2).

G. Arrighi: Problem of impulse in isotropic elastic bodies. Variations of thrust in a heavy liquid in equilibrium.

C. Morais: Spherical aberration of the fifth order of central systems.

A. Baroni: Oxidizability and structure of some industrial lamp-blacks.

G. Cotronei and A. Spirito: Phenomena of embryonic and larval growth studied in the grafting of anurans and urodelans.

H. Grossfeld: Discharge of protoplasm by removal of the electrolytes from the liquid medium in cells of tissues cultivated *in vitro*.

R. Savelli: Leucosterinoplast.

A. Orrù: Rate of growth of the hen's egg. Behaviour of the electrical conductivity of the albumen of the hen's egg with increasing and decreasing temperatures.

Forthcoming Event

Friday, April 2

Palæontographical Society, at 4—(at the Geological Society, Burlington House, London, W.1).—Annual Meeting.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Junior Scientific Officer (physics or engineering) for the Royal Engineer and Signals Board, Regent's Park Barracks, Albany Street, London, N.W.1—The Secretary (April 3).

Lecturer in Mathematics in the Sir John Cass Technical Institute, Jewry Street, Aldgate, London, E.C.3—The Principal (April 3)

Civilian Education Officer (grade III—engineering or physics) in the Royal Air Force Education Service—The Secretary, Air Ministry (E.S.1), Adastral House, Kingsway, London, W.C.2 (April 5).

Lecturer in Domestic Science and Hygiene (woman) and Lecturer in Physical Science and Hygiene (man) in the Normal College, Bangor—The Principal (April 7).

Lecturer in Geology in the University of Aberdeen—The Secretary (May 7).

Mycologist at the Rothamsted Experimental Station, Harpenden, Herts—The Secretary (June 20).

Lecturer in Biology (woman) in St. Peter's Training College, Peterborough—The Principal

Superintendent of Technical Development in the Survey Department of the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1.

British Engineers Abroad and their Prospects

IN the past, an important source of British influence and prestige has been the large number of British engineers occupying responsible positions in all parts of the world. One serious result of the many changes in world conditions since the Great War is that the position of the British engineer abroad is no longer what it was. The development of technical education in the Dominions and in India now enables these countries to dispense almost entirely with engineers from Great Britain to undertake ordinary engineering work, and from similar and other causes, including nationalistic pride, the openings in the United States, South America, Egypt and other States have been very greatly restricted. Young Argentine engineers, educated in Europe, now occupy responsible positions in their own country, which is developing very rapidly on the industrial side. In the Argentine, also, no engineer is allowed to practise on his own account unless he has graduated in, or has had his foreign qualifications revalidated by, an Argentine university : for this a very high fee is charged.

The national importance of this subject, and particularly its direct relationship to the lives and prospects of the young engineer, using the word in the widest possible sense to include technically trained men of all kinds, has caused the Old Centralians to discuss it in general meeting under the chairmanship of Sir Alfred Chatterton, who has himself had a long and distinguished career in India. The Old Centralians are the Old Students' Association of what is now the City and Guilds Engineering College, London ; they include many of the older generation in their ranks who are well qualified to give reliable evidence on the problem. The "Central" has now sent forth young engineers for more than fifty years : the first small batch included Sir Alfred Chatterton and Herbert A. Humphrey. At times more than half the students went overseas on graduation ; to-day very few are able to find work abroad.

There are still openings abroad for men of special experience who are required for specific work, but such normally involve only short-time engagements ; even in these there is increasing competition from American and Continental engineers. It is urged that in the future only first-class men would be wanted abroad and then for comparatively short periods ; the country which has the best engineering representation, whether on the professional or commercial side, will in the long run obtain the most foreign work.

Trade is said to follow the flag. The engineer carries the flag or even marches ahead of it ; he tends to buy the large quantity of material required for his projects in his native country. Hence it will be appreciated that his replacement will react adversely upon our industries.

The average Englishman to-day is strangely reluctant to go abroad ; the comforts of city life at home appeal more than the idea of roughing it There is no particular indication that the engineering schools and technical institutes are turning out more men than the industrial life of Great Britain can absorb ; indeed, at the moment when the nation is re-arming and its workshops are being largely rebuilt and reorganized, there is more than enough work. Another difficulty is the apparent prejudice against men who have returned from abroad, who often find it difficult to make a fresh start on their return. The discussion made clear that for appointments abroad there is a scarcity of men for the better positions—of all-round men possessing all the qualities which are necessary for success in the Colonies.

The immediate problem to be solved is how to prevent a period of overseas service, causing as it does a serious break in the home career, from injuring the future prospects of a technical man. Obviously no general solution is possible: the first practicable step suggested by the Old Centralians is to form an Overseas Engineers Association, which would enjoy the active support of all home professional bodies representative of engineers and engineering colleges as well as of old students' associations, consulting engineers, contracting firms and large engineering and industrial firms. Such an organization would keep a record of engineers qualified to carry out work abroad. It would constitute a source from which contributing organizations would draw engineering staff when need arose and make it easier for the employers to obtain fully trained and qualified men.

The problem is to some extent associated with the training of the engineer, and the time may be opportune to re-examine the engineering courses in relation to modern requirements. The young American engineer, for example, is more highly favoured on outdoor work by overseas employers; it may be that his training, though less theoretical, none the less fits him better for his work. Mining engineering is known to have this aspect of its teaching under consideration.

It is widely held that the present three-year undergraduate course in engineering in British universities and technical colleges should be extended to four years, not so much with a more extensive curriculum, but designed rather that the students should be given more time to think over their work and to read for themselves.

Looking at the question broadly, it would appear to have two aspects: one is that of giving Englishmen a chance to go abroad without injuring their prospects on their return, which is largely a question of organization and is possible of solution on lines such as the Old Centralians visualize. The more important aspect, however, is the technical equipment of the Englishman so as to enable him to hold his own in a competitive nationalistic world. Besides personality and character and professional knowledge, he must have ideas and originality. These can be trained out of a student more easily than developed in him.

The Trend of Population in Great Britain

THE debate on this subject which took place in the House of Commons on February 10 is one of the many signs of the increasing interest which is being felt in Great Britain in population questions. Mr. J. R. H Cartland, who moved the resolution, expressed the view, which was accepted by the House, that "the tendency of the population to decline may well constitute a danger to the maintenance of the British Empire and to the economic well-being of the nation"; and the Government was requested to institute an inquiry into the problem. No new facts were brought forward during the debate, which proceeded on what may be called orthodox lines. Attention was directed to the gradual diminution of the birth-rate since 1875; to the resulting fall in the net reproduction rate; and to the ageing of our population. The question of birth-control was touched upon, and also the present general tendency of married couples to have small families. Mr. Cartland mentioned the existence of the unofficial Population Investigation Committee, which has been formed at the instance of the Eugenics Society.

Mr. Cartland quoted the important pronouncement of the Chancellor of the Exchequer when he introduced the budget on April 15, 1935: "I must say that I look upon the continued diminution of the birth-rate in this country with considerable apprehension. At the present time it may seem that we have here a larger population than we are able to support in England. . . . But I have a feeling that the time may not be far distant . . . when the countries of the British Empire will be crying out for more citizens of the right breed and when we in this country shall not be able to supply the demand."

Mr. D. Sandys, who seconded the motion, directed attention to the rapid increase in the populations of Russia and Japan. He recalled the estimate of Dr. Enid Charles to the effect that, in sixty years' time, 64 per cent of the women in Great Britain may be past the child-bearing age. He indicated the possibility that, for want of British emigrants, the Dominions might eventually "be forced to seek emigrants from Asiatic and Eastern European countries". He is of opinion that a declining and ageing population is particularly vulnerable to attack.

These and other contributions to the debate are, no doubt, ultimately based upon the important calculations of Dr. Kuczynski, who has shown how to compute the net reproduction rate of a population by a consideration of the number of future mothers that, say, a thousand mothers will give birth to. To use the words of Prof. A. M. Carr-Saunders, in his book "World Population" (1936), "This simple and beautiful method which we owe to Mr. Kuczynski gives precisely what we need. He has applied it so far as the data are available. But in order to calculate the net reproduction rate we require data concerning specific fertility as well as specific mortality. . . . They are not available for England and Wales because the age of the mother is not recorded on the birth certificate." Here, then, is a simple step towards the calculation of accurate rates, which the Government can take at once, namely, to direct that, in future, the age of the mother shall be entered on the birth certificate.

One or two of those who took part in the debate stressed the desirability of paying attention to the quality of our population.

With regard to the unofficial Population Investigation Committee, alluded to above, this Committee, of which the chairman is Prof. Carr-Saunders, has been formed to examine the factors influencing contemporary trends of population in England and Wales, with special reference to the fall of the birth-rate. It is common ground that, unless a change—at present unforeseen—occurs in social conditions, it is probable that, after some fifteen years or so, the population of Great Britain will begin to decline somewhat rapidly. The objects of the Committee are to ascertain what are the causes of this state of things; to determine, so far as possible, the social effects of such a rapid decline; and to see how a catastrophic decline can be avoided. It has been stated on behalf of the Committee that it does not at present take part in propaganda designed to modify existing population trends.

It is to be noted that Mr. R. S. Hudson, speaking for the Government, said: "We do not propose to set an enquiry on foot, because the subject is continuously under enquiry in my Department [the Ministry of Health]. We shall welcome any assistance, but we think it is essentially a matter for the Government and not for outside societies." It may be presumed that the reports of the Population Investigation Committee will be studied and made use of by Mr. Hudson's department.

Mr. Hudson did not agree with those who hold extreme views about the population position. He said that statisticians are not infallible, and that they are not infrequently wrong in their forecasts. They are, of course, limited by the information available and they are obliged to accept existing data. They have not, alas! the gift of prophecy. Our social structure is of great intricacy, and the fall in the birth-rate may be due to many causes. One such cause may, perhaps, be a perfectly wholesome revulsion from the largely unsatisfactory conditions of the huge Victorian families of a generation or two ago. Few of those who have had the personal experience of membership of a very large family would desire their children to go through the same experience. The argument is not all on one side. There are some who think that a decline in our numbers of a few millions, if the decline could then be arrested, might not be altogether such a bad thing. From a defence point of view there would be less food to import if the country is beleaguered; we might strike a better balance between our consumption and our home production of food, if there were fewer of us; we might restore some of the lost amenities of our countryside; and the better spacing of the children might improve their quality.

It is not impossible that, as a result of the relief afforded by a reduction of our numbers, the population might tend to increase again. In the future—thirty-three years from now—if our numbers in Great Britain were to have come down by some five or six millions, from their present figure of 45·5 millions, as has been predicted, that would bring us to about the same numbers that we had in 1906. Some students of the problem would not object to such a diminution, provided always, as the lawyers say, that the diminution did not continue indefinitely, and that a stationary condition could shortly be reached. But there is no certainty about the matter, and at the best we can only make reasoned guesses. So we may hope that the Government, the Population Investigation Committee and other bodies concerned, may continue their useful labours, moved by a single desire to predict with reasonable probability the situations which may arise in the future.

Recent Progress in Chemistry

Inorganic Chemistry:
a Survey of Modern Developments. By Sir Gilbert T. Morgan and Francis Hereward Burstall. Pp. ix+462. (Cambridge: W. Heffer and Sons, Ltd., 1936.) 15*s.* net.

THIS book is not a treatise on inorganic chemistry, but appears to have developed out of three lectures delivered by Sir Gilbert Morgan in 1933 to the Institute of Chemistry, in which a survey of inorganic chemistry was attempted in the light of the remarkable discoveries of the last few years. For the startling revelation in the year 1933 of the isotope of hydrogen, and of the existence in ordinary water of an undreamt-of heavy constituent—a new variety of water in fact—can only be compared to the surprising discovery in 1894 of a new inert gas, argon, in atmospheric air, and in very appreciable quantity. That the commonest and most extensively existent liquid—forming the great oceans themselves—and the very atmosphere which we breathe, should possess concealed within them hitherto unknown constituents in such appreciable quantities, were facts indeed to give a new outlook to chemistry; and not merely to inorganic chemistry, but as regards the isotope of hydrogen, also to organic chemistry, considering that hydrogen is so important a constituent of countless carbon compounds. Indeed, at first sight an appalling vista of new hydrocarbon compounds and derivatives arises before us. When to all this we add the astonishing progress made by physicists in our knowledge of the structure of the chemical atoms, and especially of the atomic nucleus, and also in the artificial disintegration of the chemical elements—a whole series of new fugitive elements possessing induced radioactivity being called forth—there can be no wonder that it becomes necessary to take stock of the position.

The introductory chapter affords a brief survey of the development of our information concerning the ninety-two chemical elements, their classification, atomic weights and atomic sequence numbers; it marks the milestones on the fascinating road which inevitably led to the recognition that the atoms themselves have structure. The most notable referred to are the discovery by Sir William Crookes in 1879 of the cathode rays, electrons; by Moseley in 1913 of the meaning of the atomic sequence number of the element, as defining the positive charge on the central nucleus, and the number of negative planetary electrons around it, affording a wonderful explanation of the long mysterious periodic classification of the elements; and the discovery by Sir J. Thomson of positive rays, and of isotopes by Soddy in 1913, leading to the development by Aston in 1919 of his positive-ray mass-spectrograph, by which an immense number of isotopes (elements corresponding to the same atomic number but having atomic weights differing by one or more whole numbers) have been identified, one for almost every whole number up to the atomic weight of bismuth, 209. It then passes on to discuss the electronic conception of valency, the distinction to be drawn between electrovalency (as in sodium chloride), and co-valency (as in methane) involving the sharing of electrons, and to a wider application of the co-ordination theory. The second chapter deals with the key elements, the inert gases, and hydrogen. Chapter iii then proceeds to relate the facts concerning the isotope of hydrogen and heavy water, deuterium oxide, D_2O, of the properties of which latter liquid an excellent account is given, including its physiological effects as far as they have yet been examined. The chapter concludes with a description of other deuterium compounds, such as the deuteroammonias (deuteramines), deuterium halides, and deutero-methane CD_4, and heavy benzene C_6D_6 and naphthalene.

In a succession of further chapters, the periodic groups of closely related elements are dealt with in turn, and this portion of the book is full of structural formulæ, largely in connexion with the theory of co-ordination. At the end of the discussion of the eighth (iron-platinum) group, attention is directed to the necessity of remembering "that the cosmic pendulum traces out the evolution of chemical elements in a continuous helical curve which for convenience may be regarded as being described around an octagonal prism on each face of which is tabulated a vertical series of elements arranged in two alternating natural families". Referring to the noble metals and the inert (noble) gases, the authors express their opinion as hardworking chemists that "the badge of nobility seems to be idleness and detachment from ordinary mundane matters. To this ideal the inert gases—the key elements—thoroughly conform in all readily realisable circumstances. They are the *rois fainéants* of chemical elements".

A very interesting chapter (xii) follows, on the transmutation of the elements, natural and artificial, and an account is given of (1) spontaneous disintegration, exemplified by uranium and radium, (2) artificial disintegration by means of high-speed particles such as helium nuclei (${}^4_2\mathrm{He}$), protons (${}^1_1\mathrm{H}$), deuterons (${}^2_1\mathrm{D}$), or neutrons (${}^1n$), and (3) induced radioactivity by bombardment with helium nuclei (α-particles), neutrons, deuterons, or γ-rays. The light particles concerned in all these transmutations or disintegrations are considered as the "primordial stuff common to all elements". The electron, the particle of the cathode rays and the negatively electrified and planetary non-nuclear part of any atom, is considered as truly particulate, but in view of the diffraction of electrons they are also considered to possess some wave-like attributes. The positron, the positively electrified electron discovered by Anderson in 1932 as arising from the action of cosmic rays on terrestrial matter, and since also obtained by Curie and Joliot by bombardment of light elements by helium nuclei (α-particles) or neutrons, has the same ratio of electrical charge to the mass as the electron, but the sign of the charge is opposite. The positron may, indeed, be also obtained by the action of γ-rays on aluminium, copper, silver, platinum, lead, bismuth and uranium. It is not surprising that the positron should have eluded discovery so long, for its length of life is only the fraction of a second.

The neutron is a particle, first clearly recognized in 1932 by Chadwick, without charge and having a mass 1·0085 nearly identical with that of the proton, and its discovery has led to a most important change of view as to the nature of the nucleus. For the fundamental units contained in it are now seen to be protons and neutrons instead of protons and electrons. Indeed, protons and neutrons may be regarded as the same fundamental particle in two different quantum states; the neutron becomes a proton by liberation of an electron, and a proton becomes a neutron by giving rise to a positron. The stability of the nucleus appears to be dependent on the relative numbers of neutrons and protons which it contains. The proton is now fully substantiated as the hydrogen ion (${}^1_1\mathrm{H}$) of mass 1·0081 (${}^{16}\mathrm{O} = 16$), and carries a positive charge. It may, in fact, be regarded from the above as a neutron plus a positron. Protons are readily produced by passing an electric discharge through hydrogen, while neutrons are most easily obtained by treating beryllium with either γ-rays from radium or with X-rays of $1{\cdot}5 \times 10^6$ volts.

The helium nucleus (α-particle) is now accepted as possessing a mass of 4·002 (${}^{16}\mathrm{O} = 16$), and carrying a positive charge of two units, and is the only massive particle yielded by the spontaneously disintegrating radioactive elements. Although complex, containing two neutrons and two protons, it is a fundamental particle which has never been disintegrated, being uniquely stable. The nuclei of all elements of greater atomic weight than helium itself are largely made up of helium nuclei. The neutrino of which we have lately heard is probably only a mathematical conception.

The above facts are clearly brought out in the book, and it is a comfort to see them so, for of late it has not been at all easy to follow the rapid sequence of new discoveries in this sphere. It has to be remembered, however, that besides the uranium, thorium, and actinium series of spontaneously radioactive elements, potassium, rubidium and samarium have also been observed to exhibit the phenomenon of radioactivity. In the case of potassium it is probably the isotope ${}^{41}\mathrm{K}$ which shows it, the isotope which is only present to the extent of seven per cent in the metal. But since 1934 we have been confronted with the most astonishing phenomenon of all, that of induced radioactivity, by the discovery by Curie and Joliot of the effect of bombarding boron and aluminium with α-particles (helium nuclei), or graphite with accelerated protons and deuterons, the former operation producing radioactive nitrogen ${}^{13}_{7}\mathrm{N}$ and neutrons from boron, and radioactive phosphorus ${}^{30}_{15}\mathrm{P}$ and neutrons from aluminium; the latter operation also gives the same active nitrogen, which disintegrates with expulsion of a positron, and with deuterons either the same result or the formation of protons and inactive carbon. Sometimes with boron an active form of carbon resulted, ${}^{11}_{6}\mathrm{C}$. More surprising still, Fermi and his colleagues in 1934 and 1935 have produced more than forty new radioactive elements having atomic numbers from seven to ninety-two, by bombarding inactive elements with neutrons.

The neutron proves to be particularly powerful in penetrating the nuclei of many elements, giving rise to the new radioactive elements. Water and common salt can now be made to furnish respectively deuterons and radioactive sodium, this latter possessing properties very like those of radium, and it may be of use in medical work. The life-period of these new elements is very short, varying usually from a few seconds to less than one hour, and exceptionally, in the maximum, three days. For example, active carbon, ${}^{11}_{6}\mathrm{C}$, lasts for forty minutes, while radio oxygen ${}^{15}_{8}\mathrm{O}$ lasts four minutes and radioaluminium, ${}^{28}\mathrm{Al}$, five minutes. It must be remembered, however, that so long ago as 1919 Lord Rutherford had effected the artificial transmutation of nitrogen, by exposing it to α-particles emitted by radium-C, oxygen (${}^{17}_{8}\mathrm{O}$) and high-velocity protons being produced; but only one α-particle in a million was actually effective.

A further chapter (xiii), on co-ordination compounds in Nature, the arts and industries, shows how the co-ordination theory explains many cases of simulated isomorphism, such as those pointed out by the late T. V. Barker. The cases of the silicates, classified by W. L. Bragg according to their structure as determined by X-rays, are also referred to as typical examples of the application of the theory. Then comes a chapter on the corrosion of metals, in the course of which the estimate by Sir Robert Hadfield is referred to, that the world's annual loss by the corrosion of iron, steel and other ferrous metals amounts to no less than seven hundred million pounds sterling. This is followed by a chapter on alloys, and the light which X-ray analysis has recently thrown upon them. Successive chapters then deal with (*a*) carbides ; (*b*) the metallic carbonyls, and the value of Raman spectra in deciding the character of the linkage between carbon and oxygen, and in thus revealing the cause of the remarkable stability of these compounds ; and (*c*) the nitrosyl compounds ; and finally (*d*) the organic derivatives of metals and metalloids.

In reviewing a book such as this, for which one can have only the highest admiration and gratitude for its production, only one slight criticism may perhaps be permitted. The great emphasis laid on the theory of co-ordination appears to have led to the overlooking of the wonderful way in which the progressive structure of the atoms of related elements of the same family group is reflected in the similarly progressive variation in the properties of their isomorphous compounds ; in their crystalline characters (including crystal-angles), the dimensions of their similar unit structural-cells, their optical, thermal, electrical, and elastic constants. It is indeed most striking how beautifully the addition of each shell of electrons, as we pass from one member of the family of elements to the next, is seen to be revealed and marked by the advance of every natural property and physical constant. If, in addition to the reference to the alums on page 93—which do not exhibit the variation in symmetry constants, as they crystallize in the cubic system the angles of which are fixed and invariable—the cases had been considered of the rhombic sulphates, selenates, chromates, perchlorates, permanganates, and especially the monoclinic double salts with $6H_2O$ now generally known as the Tutton salts, a series of seventy-seven salts all of which have been investigated in detail, it would have been clear that in these variations, following exactly the order of the atomic complexity of the interchangeable elements, we have one of the most wonderful and complete confirmations and exemplifications of the effect of atomic structure on chemical constitution and physical character possible to imagine.

The book is excellently printed, in good sized type very pleasant to the eye, and does great credit to the publishers. A. E. H. TUTTON.

The New Hebrideans

Savage Civilisation
By Tom Harrisson. Pp. 461 +32 plates. (London : Victor Gollancz, Ltd., 1937.) 16*s*. net.

MR. TOM HARRISSON was a member of the Oxford University expedition to the New Hebrides in 1933. When the expedition left the islands he elected to remain behind, and spent a year living as a native among the natives, was for a time an official, and ended by taking part in a cinematograph film.

Whether of set purpose or not, Mr. Harrisson's narrative is arranged with consummate skill. An account of New Hebridean culture, which sets out the principal features of the economic, social and religious complex, is followed by a survey of European contacts with the islanders from the time they were first discovered by de Quiros in the early years of the seventeenth century down to and including the present joint administration of French and British under the Condominium. The author has expended considerable pains on piecing together the narrative of missionary work and the obscure record of 'blackbirders' and sandalwood traders. His critical views on the Condominium are at first hand.

The reputation of the New Hedrideans for ferocity and treachery is based on the evidence of traders and missionaries, and is a long tale of murder and aggression. The contrast between native and Europeans, even as set out here, made this almost inevitable. The narrowness of the missionary outlook, and the brutalities, cruelties and injustice inflicted on the natives by traders and labour-recruiting ships, gave unlimited provocation. At the same time, narrow as the missionaries were, they are scarcely to be blamed if their ideas in the early days were not in advance of those of their contemporaries. Mr. Harrisson's vivid and racy story of his personal experiences among unadministered natives on Malekula and Espiritu Santo serves as a foil, and redresses the balance as against the traditional view.

A tribute is paid to the medical work of present-day missions. The tendency of the population at the present time to increase is attributed in large measure to improvement in hygiene and medical attention, although the latter is still inadequate. The view of the late Dr. W. H. R. Rivers that the decline in population among the islanders of the Pacific was psychological in origin, and due to a *tædium vitæ* caused by the break-up of native custom, is regarded as disproved, at least so far as concerns the New Hebrides.

As a picture of island life seen in intimate conditions, Mr. Harrisson's book is a notable, as well as an entertaining, addition to the travel literature of the Pacific.

A New Higher Algebra

Higher Algebra
By S. Barnard and J. M. Child. Pp. xiv+585. (London: Macmillan and Co., Ltd., 1936.) 20*s*.

THIS new "Higher Algebra" will be examined with great interest by all teachers and serious students of mathematics. A book of this type is certainly needed at the present time, and the one before us should go far towards providing that stimulus which the teaching of algebra urgently requires.

The book is rather an outsize, containing 585 pages, and at a first glance the reader is inclined to wonder why. For, in the main, the scope of the book is similar in extent to that of the older higher algebra texts; yet more than the usual amount of previous knowledge of mathematics is assumed: a "knowledge of the progressions and permutations and combinations". The authors might have added that the binomial theorem for a positive integral power is also assumed.

A closer examination shows that the various topics are treated very fully indeed, and that there are, in addition, several chapters which do not appear in the usual algebra text. For example, the early part of Chapter v, which deals with complex numbers, leads to the statement and development of De Moivre's theorem, the real and complex factors of $x^n \pm 1$ and vectors. Similarly, the discussion of continuity leads naturally to the derivative of a function and to the notation and methods of the calculus.

It is apparent that the authors have attached considerable importance to placing the notion of real number on a firm and sound basis; in this connexion, the book compares very favourably with many of its predecessors. On this sure foundation the subject is "developed logically, complete as far as it goes and serving as an introduction to modern analysis". Indeed, the title might well have been "An Introduction to Mathematical Analysis".

The arrangement of the work differs from that adopted in most higher algebra texts in that only as much of a topic is introduced as is immediately necessary for the development of the subject. For example, the theory of equations is not confined to a single chapter—the topic is introduced so early as Chapter vi and is further developed in Chapter xviii; similarly with theory of numbers, polynomials, convergency, continued fractions, etc. In this way there is no suggestion of watertight compartments. Most of the topics are treated in considerable detail; this is particularly the case in the treatment of the theory of numbers and the theory of equations.

Although a mathematically minded student might work through the book unaided (and so many hints are embodied in the exercises one feels that the authors have not forgotten this class of student) it is not suitable and is not intended for beginners. The Higher School Certificate students mentioned in the preface are students taking the mathematics group—and such students are supposed to be of special mathematical ability.

Both the publishers and the authors are to be congratulated on the finished appearance of the book; the printing is excellent, though some rather small type has been used in the worked examples, and the book has an appearance of solidity which is in keeping with its contents. There are many good sets of examples. Although the book is rather large, one feels that a few historical notes would have made for even more completeness than there is already. No teacher or serious student of mathematics should be without a copy of this excellent book.

Methodik der Hormonsforschung

Von Dr. Christian Bomskov. Band 1: Schilddruse, Nebenschilddruse, Nebennierenrinde, Nebennierenmark, Pankreas. Pp. xxi+716. (Leipzig: Georg Thieme, 1936.) 54 gold marks.

DR. CHRISTIAN BOMSKOV has undertaken the production of a reference work dealing with all the methods used in the investigation of hormones The first volume contains a general discussion of methods, and special sections dealing with the thyroid, the parathyroids, the suprarenal cortex and medulla and insulin.

It would be impossible for one man to prepare a critical review of so large a field, and those who have specialized will be able to criticize details, but there can be no doubt that Dr. Bomskov has produced a work that will be very useful to those who wish to know the details of the experimental methods in use. Most of the important methods are described in full detail, and references are given to descriptions of other methods.

The general discussion is divided into sections dealing with surgical methods, histological methods, biological methods and chemical methods. These are each discussed in detail. For example, the section on biological methods deals, among other things, with the obtaining of samples of blood, stomach tubes, injections, weighing, measuring the body temperature, the registration of respiration and blood pressure, isolated hearts, perfusion and isolated plain muscle.

Each of the special sections is subdivided in the same way and the general arrangement is so good that it is easy to find any particular piece of information without reference to the index. The surgical part of each section contains full instructions, illustrated by diagrams and photographs, for removing each gland from all the commoner laboratory animals. The histological part discusses special methods appropriate to each gland and gives photomicrographs of the appearance of the glands. The biological part discusses all the effects which the different hormones produce, and methods of assay. The chemical part gives methods of isolation, chemical assay and, where possible, methods of synthesis.

This book meets a definite need and can be warmly recommended as a book of reference. It gives a reasonably complete list of the methods available, including the bad methods with the good methods, without much attempt to discriminate between them.

Lehrbuch der Mineralogie

Von Prof. Walter Schmidt und Dr. E. Baier. Pp. vi+320. (Berlin: Gebrüder Borntraegar, 1935.) 14 gold marks.

THE two authors of this text-book are in charge of the tuition in mineralogy at the Berlin Technische Hochschule. Mineralogy is a science which impinges upon several other sciences, especially geology, physics and chemistry and the number of students who have to acquire at least a general acquaintance with it tends steadily to grow. Prof. W Schmidt is responsible for the text in general, while the special sections in smaller type have been contributed by Dr. E. Baier, his assistant.

The book is in reality in two parts, although not definitely so divided. The first part, which forms a general introduction to the subject, is occupied with such parts of crystallography, optics, chemistry and geology as apply to mineralogy. The treatment is confined to general principles; nothing, for example, is said about goniometers, refractometers or other apparatus. The part includes interesting chapters upon the classes of crystal symmetry, the X-ray study of crystal structure, geochemistry and paragenesis. In the second part the important characters of the principal mineral species are concisely yet fully described, the arrangement being by elements, sulphides, oxides, silicates, etc., and halogens.

The numerous illustrations greatly add to the value of the book; thanks to the calendered paper used, they are clearly printed, but, on the other hand, the shiny surface is irksome to the reader. Mention should be made of the excellent figures in colour which are inserted at the end, representing a quartz wedge between crossed nicols and uniaxial and biaxial interference figures. Subject and mineral indexes facilitate reference to the book, and the clarity of the exposition throughout is admirable.

Back in the Stone Age:

the Natives of Central Australia. By Dr. C. Chewings. Pp. xx+161+23 plates. (Sydney and London: Angus and Robertson, Ltd., 1936.) *7s. 6d.*

DR. CHEWINGS'S experience of the blackfellow dates back to 1881, when he took up a grant of land in the MacDonnell Ranges of Central Australia. The tribes with whom he then came into contact were the Aranda (Arunta) and Loritja described in detail by C. Strehlow, a missionary of the Hermannsburg Mission, more than thirty years ago. When Dr. Chewings first met them, they were living literally in the stone age, their only cutting implements being of stone. He describes their daily life, their social organization and magical beliefs and practices as they presented themselves to the squatter, but with certain explanatory additions to make them intelligible to the ordinary reader, which he has gleaned from the work of Strehlow and Spencer and Gillen. His actual experiences as an employer of the blackfellow in the work of the station and in his contacts with them and their *lubras* tell us even more of their characters and capacities than his account of their customs.

Notwithstanding the reserve policy and the care of the Governments for the aborigines, Dr. Chewings thinks the drift towards the centres of civilization is inevitable and the ultimate fate of this people extinction. This opinion, based on long experience and understanding of the blackfellow, cannot be ignored; but the Federal Government has already carried out some of the measures advocated by the author, and experience elsewhere in analogous conditions among backward peoples suggests that extinction is by no means so inevitable a fate as he thinks it to be.

Old Diseases and New*

By The Right Hon. Lord Horder, K.C.V.O.

IT would be impossible to say that any disease has completely died out, and it would be an unwarrantable assumption to say that any disease is a new disease. All the same, it is certain that a number of diseases, which were formerly rife, not to say decimating in their effects in the past, have become obsolete, and it is almost, though not quite, as certain that other diseases have increased considerably during recent times. It is in the sense of the general nature of the problem which diseases present to-day as contrasted with years ago, that I use the words "new" and "old".

. . . . .

Diseases of the heart and blood vessels have taken a prominent position in medicine during recent years. To what degree this is due to an increase in their incidence, or to our improved methods of detecting them, or even to more notice being taken of them now that the more obvious 'villains' have quitted the stage—these are difficult questions to answer. But physicians of two, and still more of one generation ago, were very good observers, both by the bedside and in the autopsy room. So that we have their, and our own, experiences to compare, and on this basis there seems no doubt that diseases affecting the organs of circulation are relatively more rife than formerly.

What is called atheroma, or degeneration in the large arteries, is a very ancient disease. Egyptian mummies, embalmed 2,000 years before Christ, show it. Aneurysms, which are saccular dilatations of the big arteries and which were certainly fairly common until fifty years ago, have become comparatively rare. This is because the particular infection which attacks the walls of the vessel is diagnosed much earlier, and is successfully treated, But the more diffuse and less dramatic disease of the arteries which we term arteriosclerosis is very common indeed. This sort of arterial thickening overlaps with other troubles which are partly a result of the loss of elasticity in the vessel wall, and partly compensatory in nature. One of these is arterial hypertension, 'high blood pressure' as it is popularly called. This state of affairs was well known to the physicians of the generations immediately past, who could quite well detect it, even in its early stages, without the help of that instrument of precision by which it may now be exactly measured.

High blood pressure is not a disease in itself; it is an expression of disease; it is one aspect of that 'rock' or disturbance in the equilibrium by which we have defined disease. It may even, at certain epochs of life, be regarded as physiological. In many cases the increased arterial tension follows, or accompanies, increased nerve tension, the latter being of greater importance in the diagnosis than the former. The older physicians regarded high blood pressure as part of a generalized gouty state. It may well be that, with the great decline in gout in its more classical phases, such as an acute inflammation of the big toe, the same morbid processes—chemical, nervous and infective—are expressing themselves nowadays in the direction of these changes in the circulatory apparatus.

Blood pressures that are below the average are also common. These give the medical man quite as much food for thought as do the high pressures, but they have not, so far, engaged the popular imagination, because the results of them are not dramatic. Perhaps they are the modern equivalent of what used to be called 'poor man's gout'.

Then there is another disease of the blood vessels, and a serious one, which some of us consider to be a comparatively modern disease, and this is a tendency for the small arteries which supply blood to the wall of the heart to become blocked. Our technical term for this is 'coronary thrombosis'. Even when we have allowed for the number of these cases which were formerly included in the category of 'angina pectoris', the incidence of the disease is still, many of us believe, higher than it formerly was. Like all diseases of the circulatory apparatus, it is more common in males than in females. The main causative factors are as yet obscure. Tobacco, and especially cigarette smoking, has been suspected, and there would seem to be something in the life of a medical man which makes him specially prone to this affection.

There is also that curious condition termed 'halt-palsy', in which we postulate a spasm of the arteries in the legs with, in most cases, an early degree of thickening of the vessels. The main symptom is so striking that it is scarcely credible that it would not have attracted the attention of the older physicians had it been as frequent in the past as it is to-day. The patient is suddenly seized with pain in one or both legs when walking; he halts for a minute or so and the pain ceases; he starts off again and is brought up sharply at about the same distance, stops, and is again relieved.

---

* From a Friday evening discourse delivered at the Royal Institution on February 26.

Nor are our veins exempt from a 'new' disease. Inflammation of a large vein, with the formation of a clot, has been known for a very long time. But it is only during recent years that we have become familiar with a disease in which the inflammation affects a number of the smaller veins, and creeps about from one to another over a period of, it may be, several months. This tendency has given the malady the name 'phlebitis-migrans.

It is very difficult to say to what extent the work of microbes enters into the production of these troubles in our blood vessels. That it *is* a factor in some of them seems highly probable. The one thing that seems certain is that the type of germ concerned is not that which 'lays us out', as the expression goes, by a process of acute and lethal infection.

I want to deal with this last point rather more fully, and in connexion with the last of the modern diseases I will mention in which the organs of the circulation are mainly involved. This disease is what we call 'septic endocarditis'. The valves of the heart become the site of colonization of microbes, causing an inflammation which, at some time or other, produces ulceration. When this process has arrived, particles of tissue carrying masses of the microbe are swept off into the blood stream, and get lodged in the network of small vessels in various organs at the periphery of the circulation. In the great majority of cases these microbes are 'streptococci'. A form of blood poisoning is thus set up, to which the patient unfortunately, and despite all we can do, sooner or later succumbs in a very high percentage of cases.

If the germs concerned in this process are virulent germs, such as those which cause acute blood poisoning, or boils, or pneumonia, the disease is fulminant and of short duration—it may be days only. If, however, the germs are not virulent, or, as we express it, only feebly pathogenic, the disease is insidious, slow, and its duration may extend into two or even three years. There is no doubt that the old type of the disease (if I may speak of diseases in types) was generally of the former kind, whereas the tendency nowadays is towards the latter kind. Indeed, acute cases of septic endocarditis have become comparatively rare, and the chronic cases have become all too common. In the altered character of this one disease, therefore, we see illustrated the change that has taken place in bacterial diseases in general: the acute and virulent sorts have come under control, and are either obsolete or have diminished greatly in incidence; the chronic sorts have increased, and so far, have escaped control.

When we come to examine carefully the actual bacteria that are associated with these chronic infections, or, as Adami conveniently terms them, "sub-infections", we find that they are not to be distinguished by any known characters from the bacteria that are indigenous in our bodies during health. If, however, they pass the barriers of the mucous membrane, and enter the solid tissues of the body, or the blood stream—except perhaps in such minute numbers as can be promptly killed or as promptly eliminated by the kidneys—diseases may arise, generally of this insidious and chronic form. There are several more of such diseases, in addition to septic endocarditis, but I must not stay to speak of them. The general term under which we speak technically of this set of diseases is 'focal sepsis'. It is in connexion with them that many of our patients talk to us nowadays in the language of the bacteriological laboratory—perhaps with the possessive proudly added—as "*my* streptococcus, doctor", or "my bacillus coli".

What the factors are that determine these sub-infections we are as yet unable to say. We speak, rather loosely I am afraid, about 'lowered resistance', but we are quite unable to define this term exactly. Until we know more about the nature of the natural defences of the tissues against bacterial invasion, and perhaps more, too, about possible mutations in the bacteria themselves, this part of the mechanism of sub-infections will remain obscure.

If we turn now to another group of diseases which bulks largely in modern medicine, those associated with what are called the internal secretions of the body, or hormones, it is still more difficult to say if these have increased in frequency, because our knowledge of these substances is comparatively recent, and the study of what we call endocrine imbalance is therefore also recent.

With that natural desire to unload the defects of behaviour upon anything that comes to hand which is outside our control, we like to think our 'glands' are at fault when our temper is not well governed, or when we are moody, or when, in any way, we are anti-social. Allowing fully for this weakness, there still remains a large residue of cases in which we can trace the jostle suffered by the normal equilibrium to disturbances in this part of our economy.

If we include diabetes in this group, on account of its close association with the internal secretion of the pancreas, we have figures which show a considerable increase in the prevalence of this disease. The number of diabetics in Great Britain in the year 1923–24 was estimated at 29,000. The estimate for 1934–35 was 70,000. In the United States the increase is said to be even greater. Since diabetes is not a disease of old age, these figures are not explained by the increase in the expectation of life which has taken place during the same period.

In the sphere of the nervous system, the position appears to be this: that whilst the incidence of what we term the major psychoses, that is, the forms of mental derangement requiring institutional treatment or special nursing, remain much as they did, there is a large increase in the minor psychoses or psychoneuroses, as they are more properly termed. The condition called anxiety neurosis is very common and neurasthenia still more so—indeed neurasthenia is one of our major problems in medicine to-day, both as regards its causes and its treatment.

The first appearance of that form of inflammation of the brain called encephalitis lethargica is quite uncertain, because in the severe cases of influenza cerebral symptoms have often appeared, causing confusion in diagnosis. But serious outbreaks have occurred in the present generation, as well as many sporadic cases. The number of cases in which the brain symptoms appear, the fever having been overlooked, or being absent altogether, is probably still under-estimated. The same applies to influenza nerve symptoms, though these are, of course, less serious. Acute poliomyelitis, better known by its trivial name, infantile palsy, has close affinities with encephalitis, and as there is authentic evidence that this disease existed long ago in Egypt, it is probable that encephalitis did also.

The claim that there *are* new diseases might well be supported, even though they are more interesting than extensive. By way of illustration, there are diseases which are the direct result of modern treatments. There is what we call serum-sickness, for example, a state of things which often follows a week after the injection of serum derived from the horse, as for diphtheria or tetanus.

There are diseases which follow the use of X-rays and of radium. There are effects which we do not aim at, but cannot sometimes avoid, following the use of a number of drugs, both inorganic and organic. We may do an arthritic patient a great deal of good by injecting him with a preparation of gold, yet the metal may disturb his system in such a definite manner that we do, in effect, set up another disease. We may clear a man's tissues of gout by means of a drug called atophan, and give him disease of the liver. We may assist considerably in the healing of a gastric ulcer by the intensive use of alkalis, and induce a disease called alkalosis. A Scots patient for whom I once ordered bicarbonate of soda was so struck by the relief of his stomach ache that he expressed his fear lest his body would have to pay for a drug which was so "verra powerful". His fear had an element of justification.

By the use of insulin we are able to keep the amount of patient's sugar circulating in a diabetic blood at a proper level. But an overdose may reduce the sugar below the normal threshold and the result is a well-recognized disease.

Then there are new diseases incident upon new occupations. Occupational diseases were well known to the old physicians. Paracelsus described the lung disease of miners at the beginning of the sixteenth century. But T.N.T., and the disease of the liver which may follow from handling it, are entirely modern; and since our forefathers did not make war with poisonous gases, the diseases incident upon their inhalation are peculiar to this more civilized age.

Looking now at the germ diseases over which we still have practically no control, they are probably, nearly all of them, the result of infection of the body by a special type of microbe which we call a virus. Filtrable viruses, they are sometimes termed, because the infecting agent passes through the finest (porcelain) filter available. This infective material has been proved to contain extremely minute particles: the name "elementary bodies" is given to them. We owe the first description of these particles to a Scot named John Brown Buist, who found them in the calf lymph used for small-pox vaccination and also in material removed from small-pox pustules. After the delay that so often follows original observations like these, a number of other workers have studied these Buist bodies, and have confirmed their presence and importance. British bacteriologists have been amongst the foremost in these researches, and in particular, Dr. Mervyn Gordon and Prof. J. C. G. Ledingham.

There is a lot of evidence for regarding virus bodies as being the cause of influenza, encephalitis lethargica (or sleepy sickness), infantile palsy, mumps, measles, and also (some would add) the common cold. What is equally important, there is a growing belief that the mystery of cancer, a disease which equally lacks control in the true sense of the word, may find part of its solution in the discovery of specific virus bodies. That cancer *is* a microbic disease becomes more and more a convincing hypothesis as intensive research into its problems continues. It is not difficult to visualize these minute virus bodies—each one is from five to ten times smaller than the ordinary micrococci—settling like so much dust, inside the very substance of the cells of an organ, successfully colonizing there (successfully, that is, from their own point of view) and thoroughly disorganizing the cell economy. The life of the cell continues—it is not killed—but it is stimulated (irritated) into that state of chaotic over-growth which is the very essence of cancer. I do not know of any problem connected with cancer as a disease which is not capable of explanation upon the basis of a hypothesis like that. We shall see, if we continue to be patient and painstaking and work with some vision, if this be the truth or not.

It is often held that the incidence of cancer has increased during the past fifty years. This is very difficult to prove. Several possible fallacies come into the argument, especially improved diagnosis, and better methods of registration. Cancer is a disease of the second half of life ; indeed, to a large extent it is a disease of old age. An increase in the number of cases of cancer may therefore be no more than a confirmation of what we know already—that the expectation of life has risen by 15 years during the past two generations. Old age brings not only its own infirmities but also its own diseases. Senility is itself a disease, and it is on the increase. If we go on as we are going, a man giving this lecture in sixty years' time will probably stress senility as being one of the most striking of the 'new' diseases.

It seems to me that certain generalizations emerge from this discussion of 'old' and 'new' diseases. There has certainly been a swing over, as it were, from those frequent and devastating gusts of acute and virulent germ diseases to more insidious and chronic maladies. Life was very precarious in Elizabethan days and in the centuries immediately preceding and following them. We must remember that what we know to-day about those terrible scourges refers only to the big epidemics ; there must have been thousands of what are called 'sporadic' cases, and there were places where some of these pests made themselves endemic. So that, in addition to the big waves of fevers that brought death in great swathes, there was the steady, constant loss of life in these other ways. Sydenham estimated that in his day fevers accounted for 70 per cent of the whole of medical practice. To-day this figure is not more that 10 per cent.

The Elizabethan was very alive to-day and very dead to-morrow. If we exclude influenza, which still seems to possess something elemental in its potentialities—that is, judging by 1918–19, rather than by the mild epidemic we have just experienced—there are no diseases nowadays that spell violence as diseases did in Sydenham's time. Unless we call venturing upon the streets and roads a disease. Or war ; which is, after all, the greatest of all modern diseases, though it is a disease of the mind and not of the body. It has existed since the race began, but its casualties were formerly trivial by comparison with those due to disease. To-day the proportions are reversed. The Great War cost us more than 700,000 lives and 2½ million total casualties. At the beginning of 1920 there were just over one million war pensioners, and even in March of 1936 there were 400,000 permanent pensions being paid. Of these, 40,000 were on account of mental and nervous diseases. Science has reduced enormously the casualties due to the attack of the microbe upon man ; but science has increased in much greater proportion the casualties due to the attack of man upon man.

Then, again, the question arises, what of the integral stuff of our bodies and of our minds ? It looks as though our enemies have become the men of our own house, rather than those who have got entrance from without. Why is this ? Has something gone wrong with the control ? Or, to change the metaphor, are we discharging the battery at too high, and charging it at too low, an amperage ? *Why* are we becoming the preys of our own saprophytes ? *Why* is the tubing of our blood vessels, and why are the working parts of the pump, wearing so badly ? These questions cannot yet be answered, or not in this place !

We are living longer ; that is one of the most striking results of the past fifty years of hard but intelligent work on the part of those who have inspired and administered our public health services. Does someone ask *cui bono ?* Why live longer if we cannot live more healthily and more happily ? For it certainly does look as though, for many of us, our lives become 'thin spun' long before the 'abhorred shears' are due—so why take such pains to defer them ? Is our meticulous care of our shadowy present worth it ? Is it worth suggesting security to ourselves in a gas mask and an (alleged) bomb-proof cellar ? But surely the answer is with us who do the living ? How *long* a man lives depends upon his ancestors and the state of the public hygiene. How *healthily* and how *happily* he lives depends upon himself. Also be it observed that mere absence of disease is not enough. Therefore we welcome an attempt by the State to organize the national physique. Later, but I trust not too late, perhaps we might do something to organize the national mind ; and so get back some of the *zest* for living that we seem to have lost, and the ability to enjoy this immunity from disease that we have accumulated.

The Transition State in Chemical Kinetics

By Prof. M. Polanyi, University of Manchester

THE energy barrier separating the initial and final states of a reaction has ceased to be a fictitious concept since the main principles of chemical inertia were discovered by F. London (1927). For some simple cases, we can now calculate the energy changes occurring during the process of reaction, and follow the paths along which the atoms move. We can, in particular, obtain in many cases a clear picture of the configuration which corresponds to the top of the energy barrier. This configuration is called the *transition state* τ of the reaction.

It is interesting to deduce Arrhenius's equation by thermodynamical considerations relating to the transition state. At chemical equilibrium we see the atomic configuration changing forwards and backwards between the initial and final states of a reaction, and passing on each occasion through the transition state τ. The positions which the atomic system takes up between the initial and final states form a continuous sequence and can, therefore, be defined by one co-ordinate l which is called the 'reaction path'. At equilibrium we have a certain infinitesimal number of reacting systems in the transition state, that is, near the top of the energy barrier. This number (population) can be equated to the concentration product of the reactants, say, $c'.c'' \ldots$ into an infinitesimal equilibrium constant $K_1 dl$.

$$\text{Population } (\tau) = c'.c'' \ldots K_1 dl$$

Since

$$\text{Population} = \text{birth-rate} \times \text{average life},$$

we can calculate the birth-rate by noting that the average life of τ is equal to a thermal velocity v over dl, and that thus:

$$\text{Birth-rate } (\tau) = c'.c'' \ldots K_1 v.$$

Now the birth-rate of τ is equal to the rate of the forward reaction (1) plus the rate of the back reaction (2), and since at equilibrium, rate (1) = rate (2)

$$\text{rate } (1) = c'.c'' \ldots K_1 v/2$$

and the rate constant k_1 is

$$k_1 = K_1 v/2 \ldots \text{(A)}$$

Applying van t'Hoff's isochor to K_1, we obtain:

$$\frac{d \log k_1}{dT} = -\frac{q}{RT} + \frac{d \log v/2}{dT}.$$

The second term on the right being negligible, this gives $k_1 \propto e^{-q_1/RT}$, that is, Arrhenius's equation.

The 'transition state method' of treating problems of reaction velocity consists in a generalization of this procedure to other variations than those of temperature. Supposing the reaction rate in solution changes under the influence of hydrostatic pressure π, then applying thermodynamics to equation (A) we obtain

$$\frac{d \log k_1}{d\pi} = \frac{V_1 - V_\tau}{RT} + \frac{d \log v/2}{d\pi},$$

where V_1 is the volume of a solution containing one mol of the initial state and V_1 the volume of a solution containing one mol of the transition state. We can again neglect the differential of v and set

$$k_1 \propto e^{(V_1 - V_\tau)/RT}$$

The fruitfulness of this deduction depends on our capacity to interpret the values of $V_1 - V_\tau$ derived from observation. This is easiest in the case of reactions of the type $A + B = AB$; for these we can predict $V_1 - V_\tau$ with some accuracy. The configuration of the transition state must here be intermediate between the configuration of the initial and final states and quite near to that of the final state, and the same will hold for the volume V_τ. V_τ will lie between V_1 and V_2 (the volume of the final state) close to V_2. This has, in fact, been confirmed by experiment. It thus seems that the rate at which reaction velocity varies with hydrostatic pressure is predictable for certain types of reactions.

The method is capable of further generalization. Variations in reaction velocity can be observed under the influence of an electric field, for example, when the rate of electrolytic evolution of hydrogen is governed by the polarization (ϵ) of an electrode. In this case we might write for the equilibrium constant K which relates the concentration of the hydrogen ions in solution to that of the hydrogen gas at the electrode,

$$\frac{d \log K}{d\epsilon} = \frac{n}{RT},$$

where n is the effective (molar) charge of the proton. The effective charge is equal to $F = 96{,}500$ coulombs for the hydrogen ion which constitutes the initial state, and equal to zero for the final state when the proton is neutralized at the electrode. If we assume that in the transition state the effective charge has an intermediate value, say, αn, α being about 0·5, we obtain

$$\frac{d \log K_1}{d\varepsilon} = \frac{\alpha F}{RT} ; \alpha \sim 0.5 ;$$

which on comparison of the differential of equation A with respect to ε and by neglecting $\frac{d \log v/2}{d\varepsilon}$ can be identified with $\frac{d \log k_1}{d\varepsilon}$. If we measure k_1 by the intensity i of the current, we have $\log k_1 \propto \log i$ and finally

$$\log i = \frac{\alpha F \varepsilon}{RT} + \text{const.} ; \alpha \sim 0{\cdot}5 ;$$

which is the well-known over-voltage equation of Tafel. This equation is thus interpreted as indicating that the effective charge of the transition state lies about half-way between that of the initial and the final states of the reaction.

The field of such generalizations has been extended to other variations of reaction velocity arising from changes in chemical constitution, from the transfer of a reaction from the gas phase into solution, and from variations of solvents.

The principle consists in introducing a parameter of the transition state arising from the general equation

$$\frac{d \log k_1}{d\chi} = \frac{p_1 - p_\tau}{RT} \quad . \quad . \quad . \quad (B)$$

where χ is an external parameter causing the variation in reaction rate and $p_1 - p_\tau$ is the change in the corresponding parameter accompanying the formation of the transition state from the initial state.

The advance in the various directions to which I have referred is, as yet, tentative, but the method seems to provide a rational framework for the interpretation of many empirical rules of reactivity as well as a guidance to the discovery of new relationships.

REFERENCES

The derivation of a reaction velocity from a statistical treatment of the transition state was first put forward by Wigner and Pelzer (*Z. phys. Chem.*, B, 15, 445 ; 1932) in their treatment of the reaction $H + H_{2}\text{para} = H_2 + H$; this treatment was generalized by Eyring (*J. Chem. Phys.*, 3, 107 ; 1935) and by Evans and Polanyi (*Trans. Far. Soc.*, 31, 875 ; 1935). The thermodynamic formulation equation (*A*) is due to the latter authors and to Wynne-Jones and Eyring (*J. Chem. Phys.*, 3, 492 ; 1935) Equation (*B*) and its various applications sketched out in this paper are due to Evans and Polanyi (*Trans Far. Soc.*, 31, 875 , 1935 ; 32, 1333 ; 1936).

Obituary Notices

Sir Albert Kitson, C.M.G., C.B.E.

SIR ALBERT KITSON, whose death occurred on March 8, was a geologist of world-wide repute, and the discoveries which he made and which are now being exploited in many parts of the world entitle him to be classed as one of the foremost economic geologists of his time.

Kitson was born in Manchester in 1868, but when six years old accompanied his parents to Australia. He entered the Civil Service of Victoria by competitive examination, and having a bent for geology he took courses in this subject at the University and School of Mines, Melbourne. Later on, he also took courses in mining and surveying, thereby equipping himself for the career which he was afterwards to follow.

As a result of his studies, Kitson was transferred to the Geological Survey of Victoria. In 1903 he became senior geologist, and while he occupied this post was responsible for some magnificent field work. In 1906 he went to Southern Nigeria as principal of the Mineral Survey, but resigned in 1911. In 1915 he was appointed director of the Geological Survey of the Gold Coast, which position he held until 1930 when he retired, having reached the age limit. So valuable were his services considered, however, that his period of service was extended five years beyond the usual period. It was while he occupied this position that his name became known in ever-widening circles, not only on account of the remarkable discoveries which have already been referred to, but also on account of the energy and drive which he put into his work. By many of the Gold Coast natives he was regarded as a fetish doctor owing to his seemingly reckless handling of snakes, an ability which he had acquired during his boyhood in the Australian bush. Nor did he know what fear meant. In the early days of his Southern Nigerian appointment, when he was geologizing in the wake of a punitive expedition, he was continually in trouble with the military authorities as he was always getting ahead of them.

Among Kitson's discoveries on the west coast of Africa may be mentioned the black and brown coalfields (Nigeria), manganese, bauxite, diamonds (Gold Coast) and many others of lesser importance, the development of which has contributed enormously to the prosperity of these two colonies. But he followed up these discoveries by coming home and describing their possibilities to interested parties in the business world of London for, as already indicated, he had the economic side of geology very strongly developed. Moreover, he was a great enthusiast and he managed by some subtle gift to impart his enthusiasm to others.

After his retirement, Kitson was requested by the Government of Kenya to carry out a preliminary geological survey with special reference to the discoveries of gold which had begun to interest financiers. He therefore went out in 1932 and made his report. All his recommendations were accepted by the Government, and although Kenya may never become one of the world's great goldfields, the progress made since his report was written is quite remarkable.

Kitson was responsible for many papers; indeed he was a most prolific writer on his subject. In 1918 he was awarded the Wollaston Fund by the Geological Society and in 1927 the Lyell Medal. He was president of Section C (Geology) at the Johannesburg meeting of the British Association in 1929; and he attended geological and mining conferences in many countries, nearly always as a responsible delegate. On his retirement he was warmly commended by the Secretary of State for the Colonies for his services on the West Coast. He was knighted in 1927, having previously been awarded the C.B.E. in 1918 and the C.M.G. in 1922. Within recent years he joined the boards of several mining companies, a distinction which has seldom fallen to any geologist. He was actively associated with many scientific and technical bodies and on some of these the present writer, who knew him for many years, was also actively associated.

Kitson had always something useful to say when he did take part in discussions, and his keenness and his enthusiasm will be sadly missed. He was indeed a remarkable man as the foregoing will indicate; it falls to the lot of few to be as well known 'in the City' as in scientific circles.

WE regret to announce the following deaths:

The Duchess of Bedford, D.B.E., fellow of the Linnean Society, author of papers on ornithology, well known for several aeroplane flight records, lost during an aeroplane flight last week, aged seventy-one years.

Brigadier-General Sir Capel Holden, K.C.B., F.R.S., director of mechanical transport in the Ministry of Munitions during the Great War, on March 30, aged eighty-one years.

Prof. Dragutin Gorjanovitch-Kramberger, professor of palæontology and geology in the University of Zagreb, who in 1896 discovered the remains of early man of Krapina of Neanderthal type, aged eighty years.

Mr. C. E. Haselfoot, fellow (formerly dean) of Hertford College, Oxford, lecturer in mathematics in Wadham College, from 1888 until 1913, on October 28, aged seventy-two years.

Prof. Paul Janet, director of the School of Electricity, Paris, formerly professor of physics in the University of Paris, aged seventy-three years.

Sir Thomas Mottram, C.B.E., formerly H.M. Inspector of Mines, on March 24, aged seventy-eight years.

Prof. D. A. Low, emeritus professor of engineering in East London (now Queen Mary) College, on March 24, aged eighty years.

News and Views

Prof. A. Hutchinson, O.B.E., F.R.S.

BY the retirement of the Master of Pembroke College, Cambridge, Dr. Arthur Hutchinson, emeritus professor of mineralogy in the University, under the age limit of the new statutes, the University loses the services of one of its outstanding figures. For many years as lecturer in crystallography and demonstrator of mineralogy during the long tenure of the chair of mineralogy by the late Prof. Lewis, before himself succeeding to the chair in 1926, Dr. Hutchinson was the life and soul of that Department, and the inspirer of most of the original investigations carried on therein. His own contributions to original research were many and noteworthy, and his affectionate care for the valuable and ever-increasing collection of crystals and minerals in the New Museums, while at the same time it was kept usually available for actual study, was obvious to all who entered the Department; it was indeed often remarked upon by the many distinguished foreign mineralogists who visited Cambridge, and enjoyed the kindly hospitality of Dr. Hutchinson and his devoted wife, herself the sister of another eminent man of science, the late Sir Arthur Shipley.

AMONG the most useful of Prof. Hutchinson's contributions to the advance of his subject were his ingenious aids to graphical crystallography, such as the Hutchinson stereographic protractor and net, and his simplification of crystallographic calculations by graphical methods. Also his universal apparatus for the measurement and optical examination of small crystals, described to the Mineralogical Society in 1911, has proved to be of maximum utility at minimum cost. Again, in his work in collaboration with Dr. A. E. H. Tutton on the exceptionally interesting optical properties of gypsum at different temperatures, it was a clever device of Dr. Hutchinson which enabled the exact temperatures for the changes to be determined for the first time with absolute certainty. Indeed, extreme accuracy was characteristic of him, and another instance of it was afforded by his memoir on colemanite, in which he showed that the so-called neocolemanite was a myth, being identical with colemanite itself, the mistake of other observers having been due to inaccurate methods. Dr. Hutchinson's services to the Mineralogical Society, to the membership of which he was elected so long ago as 1890, can never be overestimated, whether as member of council, foreign secretary, or president (1921–24). But fortunately, Dr. Hutchinson is retiring in excellent health, so that we may trust that his interest in the work of the Society may be long continued.

Prof. A. E. Trueman

THE chair of geology in the University of Glasgow, rendered vacant through the resignation of Prof. E. B. Bailey on his appointment as director of the Geological Survey of Great Britain, is to be filled by Prof. A. E. Trueman of the University of Bristol. Prof. Trueman was educated at High Pavement School and University College, Nottingham, and he received the degree of D.Sc. in geology from the University of London in 1918. He was appointed assistant lecturer in geology at Cardiff in 1917, and head of the Department of Geology in University College, Swansea, in 1920. In 1933 he succeeded Prof. S. H. Reynolds as Chaning Wills professor of geology in the University of Bristol. Prof. Trueman is best known by his researches in problems of Coal Measures Geology. In particular, he has taken an important part in the zoning of the Coal Measures of South Wales by means of non-marine lamellibranchs, and in their correlation with other areas. He has also co-operated in research work carried out on dust from coal mines, in connexion with its bearing on the problem of silicosis among miners. In addition to his purely scientific work, Prof. Trueman has interested himself especially in the Workers Educational Association and other university extension activities. He is also a member of a committee appointed at Blackpool last year by Section C of the British Association to study the position of geology in the present educational system.

The National Government and Democracy

A PAMPHLET entitled "The Case for the National Government" by Earl de la Warr, chairman of the National Labour Committee, stresses the failure of democratic politicians to grapple with the problems of the new world with which the man of science is confronting this generation. In many countries they are unprepared for this new challenge of the scientific world, and the seriousness of the new problems and the pace at which solutions are demanded is too much for politicians either of the Left or of the Right. He believes that dictatorships have revived because democratic politicians have been unable or unwilling to adapt themselves to the new age and therefore have been weak and indecisive in dealing with modern problems. Earl de la Warr claims that Great Britain, in its National Government, is giving the democratic reply to conditions which have led to dictatorships elsewhere. Since we are finding our way into a new world, much of the work of the Government is necessarily experimental.

THIS new world is very largely the result of the discoveries and inventions of the chemist, the physicist, the biologist in the last hundred years or so. Science has given more to the world in that period than in any previous thousand years. Hitherto the politician has been concerned rather with the rights and liberties of man than with the possibilities of transforming everyday life by organizing the gifts of the scientific worker. The economic and social sciences have barely begun to keep pace with the physical and technical sciences. Nations should now be thinking not in terms of access to raw materials but to markets or even more of the creation of markets. The problems of to-day are the problems not of shortage as in the past but of plenty. The challenge of science cannot be met by limiting production or inventions but by dealing on rational and scientific lines with the factors which undermine national physique and welfare such as poverty, malnutrition, overcrowding. This is a matter of scientific organization whether of distribution, consumption, education or the like, and that such an approach is not easily turned into a fighting appeal to a democratic people is a real difficulty. Unless, however, democracy succeed in directing man's inherent pugnacity into fruitful and creative channels, the downfall of civilization is certain, and Earl de la Warr believes the National Government is an attempt to give a wise and courageous answer to many of these vexed questions.

English Terms in Scientific Writings

THE S.P.E. Tract No. 48 (Oxford, Clarendon Press; 1937) contains three articles that are of interest to writers on scientific subjects. Mr. Otto Jesperson deals with the use of such terms and phrases as 'almost' before a verb or noun, 'kind of' or 'sort of', 'rather than', 'as much as', and so on. Sir W. A. Craigie notes many variations in the spelling of English words, but concludes that "the irregularities of modern English are of slight importance in relation to the language as a whole". Dr. C. G. Darwin's article on "Terminology in Physics" is reprinted from NATURE (138, 908; 1936). His main points, it will be remembered, are: the difficulty of translating appropriately a term from a foreign language, the use of an inventor's name instead of a descriptive term, and the use of adjectives, such as 'microscopic' and 'macroscopic', to express opposite ideas by words of nearly the same sound and spelling. Others may be added to this list. For example, 'sismi', an equivalent for earthquakes, is simple to pronounce in Italian, and 'séismes' still more so in French, but the corresponding English term 'seisms' is intolerable. Another point is the formation of the singular of a word that has come down to us in the plural only. It would seem permissible, because natural and convenient, to use 'scree' as the singular of the Icelandic word 'screes'.

Popularization of Science

IN an address on the "Popularisation of Science" when receiving the fellowship of the American Institute, New York, on February 4, "for interpreting to the people of the nation the rapid progress of science upon which modern civilization depends and for the organised dissemination of research findings as news", Mr. Watson Davis said that the reporting and interpretation of science failed of its purpose if it did not bring about an appreciation and utilization of scientific method in everyday life. This he believed was best achieved by giving the mass of the people, through accurate and interesting accounts of science's successes and failures, some understanding of the essence of science which would lead them to apply it more widely to our everyday life, our human relationships, business and government. Many of the ideals we most cherished such as liberty, opportunity, the pursuit of happiness, freedom, democracy, were achieved by the utilization of scientific method, and the mistakes of democracy were best corrected by science.

THIS belief, that the only way of making democracy safe for itself was to make it more intelligent and accordingly more scientific, inspired the founders of Science Service, E. W. Scripps and Dr. W. E. Ritter. Many opportunities of such service were as yet only imperfectly used. For example, the scientific aspects of the recent disastrous floods had received little publicity, and the possibilities of books and magazines as media have yet to be fully developed. In this work quality is all important, and the first objective is the exact opposite of propaganda. It is to present facts in a readable and interesting form, on which the reader could base his own opinions on a subject of politics, sociology or his duty to his fellows. In recalling this statement of the founders of Science Service as to its objectives, Mr. Watson Davis emphasized that not even science must be allowed to become a dictator. It should set the example for straight thinking, confident that the process of democracy, guided by scientific method and reason, would give effective results.

Development of the Oil Engine

THE millions of compression-ignition oil engines in use to-day have all sprung from the initial work of Herbert Akroyd Stuart (1864–1927) and Rudolph Diesel (1858–1913), whose outstanding patents were taken out in 1890 and 1892 respectively. Vast sums of money have been spent by Governments, firms, institutions and individuals in experiments with oil engines, but just as the first successful Diesel engine was the outcome of the work during 1893–97 of the Maschinenfabrik-Augsburg-Nurnberg, so the success of the engine invented by Akroyd Stuart—known as the "Hornsby-Akroyd" engine—was due to the pioneering work of Messrs. Hornsby and Sons, Ltd., of Grantham, now Ruston and Hornsby, Ltd., of Lincoln. Having offered his patents to various gas engine makers, Stuart approached Messrs. Hornsby, and in 1891 they agreed to take up the development of Stuart's engine on a royalty basis. The necessary experimental work was entrusted to Mr. J. W. Young, who in a paper entitled "Notes on the Practical Development of the Oil Engine" read to the Newcomen Society on March 17, gave an interesting account of the difficulties which had to be overcome before the "Hornsby-Akroyd" engine could be placed on the market.

STUART'S principal patents were No. 7146 of May 1890 and No. 15994 of October 1890 and these covered compression ignition and airless injection, and also the use of a vaporizer. The most difficult problem was that of combustion, and many forms of vaporizers were tried. The construction of oil engines, too, demanded a higher standard of workmanship than the steam engines, and cylinders, pistons and piston-rings were all the subject of many experiments. Both fuel oil and lubricating oil raised many problems, especially as the oil refiners of that time had not succeeded in removing certain resinous bodies from the oil. In connexion with this, Mr. Young was sent to Russia, where Messrs. Nobel Brothers co-operated in introducing a uniform standard of distillation. As regards the development of the "Hornsby-Akroyd" engine Stuart took no part after 1891. He migrated to Western Australia about 1900 and died there on February 19, 1927. The so-called semi-Diesel engine is properly an Akroyd-Stuart engine, and nearly all makers of Diesel engines now use his method of airless injection, and not air-blast injection as introduced by Diesel.

Chair in Biblical Archæology: an Appeal

AN appeal for funds to endow a chair in biblical archæology in connexion with the Institute of Archæology of the University of London, has been issued over the signatures of the Archbishop of Canterbury, Sir Frederic Kenyon, Sir George Hill and Sir Charles Peers, should meet with a ready and liberal response, especially as the generous gift by Sir Charles Marston of £1,000 has already reduced substantially the amount which it is considered necessary to provide. Palestine demands of the field worker a widely extended and detailed knowledge of the general cultural and historical background, owing to its geographical position and its political, economic, and cultural relations with contemporary peoples. The institution of a chair in biblical archæology, by making provision for that preliminary training in acquisition and manipulation of the historical and cultural facts of the Ancient World, should go far towards conserving the time and energy of senior members of an expedition, which must be devoted to the training and supervision of the younger workers in the field. Not only does the installation of Sir Flinders Petrie's Palestinian collections at the Institute of Archæology make this an opportune moment to inaugurate such a chair, but also the results which have been achieved by recent excavation in Palestine, as for example at Lachish, Jericho and Gaza, as well as indications of the bearing of Palestinian material on the excavations now being carried out in Syria, all point in the direction of the imminent possibility of important additions to knowledge. This should be an additional stimulus to the British public, who have always looked kindly upon research in Palestine. Contributions may be sent to Mr. E. S. M. Perowne, 7 Great James Street, Bedford Row, W.C.1, or direct to the Westminster Bank, Marylebone Branch, 1 Stratford Place, Oxford Street, W.1, marked "Institute of Archæology".

Earliest Monumental Remains in Iraq

THE joint expedition of the American School of Oriental Studies and the University of Pennsylvania, in continuing the excavation of the mound site of Tepe Gawra in Mesopotamia, upon which it has been engaged now for several seasons, has uncovered some remarkable remains of a monumental character in the level of stratification now being explored. This level is the thirteenth from the surface in the series of some twenty strata of deposits of which preliminary exploration showed the mound to be composed before virgin soil was reached. Its culture is that of the 'painted pottery' people, of which evidence has been found wide-spread over early western Asia and the ancient East, from southern Russia to China, and dated at approximately 4000 B.C. and later. In a recent report from Prof. E. A. Speiser, field director of the expedition, according to a communication circulated by Science Service, Washington, it is stated that the expedition has discovered the acropolis of the city. It consists of a northern temple, eastern shrine and central temple, which with other buildings surround an open square, or court, paved with gravel covered with stamped clay. In the central temple, all the rooms show traces of a purple-red paint. The buildings are of an imposing character, and being the earliest known of their kind, carry back the practice of monumental architectural art to a much earlier phase of civilization than had hitherto been thought, while Tepe Gawra is shown to be the centre of an organized civic life, on a scale and of a kind for which hitherto there had been no evidence in connexion with the presumedly primitive people of the stone age to whom the painted pottery had been ascribed.

Soil Drift in South Australia

MR. F. N. RATCLIFFE, of the Council for Scientific and Industrial Research, Melbourne, has sent a long communication, for which space cannot be found, discussing an article in NATURE of December 19, based on his recent report on wind erosion (drift soil) in the arid pastoral belt of South Australia. Mr. Ratcliffe appears to hold the opinion that the processes taking place in that part of the world differ from the causes which have, and are, producing the man-made desert in other regions. The factors responsible for the destruction of the vegetation in Australia are drought, overgrazing by stock and the rabbit. The extension of the Sahara and the dust bowl in America are (omitting the rodent) being brought about by the same causes—excessive cultivation or grazing, or both combined. But the word 'drought' as used in Australia and America requires definition. This is the chief factor in the case. The actual results of the over-utilization are the same, whether the land is actually covered up by sand, or the top soil is blown away, or the soil deteriorates *in situ*: the spring water-level is lowered in the soil, not by *drought* as ordinarily understood by that word, but by the desiccation brought about by the acts of man. The end is a desert, and the water disappears from the surface and sinks to varying depths in the soil. As regards wind erosion, that is, dust storms, few travellers or inquirers who have studied desert regions, many of them man-made, can have failed to become acquainted with desert clouds of that type, whether consisting of sand or blown soil of valuable types. Mr. Ratcliffe has conceived the idea that the erosion or drift in Australia is something apart. It would appear to be only a type.

Oceanography in New South Wales

THE seasonal fluctuations in nutrient salts in European coastal waters and their bearing on the production of phytoplankton and ultimately on the fertility of the sea are now well understood. However, there are still huge areas of the waters of the world, including those adjacent to civilized countries carrying on original research, about which nothing whatever is known. Off the New South Wales coast, W. J. Dakin and A. N. Colefax ("Observations on the Seasonal Changes in Temperature, Salinity, Phosphates, and Nitrate Nitrogen and Oxygen of the Ocean Waters on the Continental Shelf off New South Wales and the Relationship to Plankton Production", *Proc. Linn. Soc. New South Wales*, **60**, 303–314; 1935. Sydney University Reprints, Ser. XIII (Zoology), **3**, No. 8; 1936) have now found complete exhaustion of both phosphate and nitrate by spring and autumn phytoplankton outbursts. The depletion of nitrate persists through the summer as in the seas around Great Britain, but phosphate is replenished more quickly. On the whole, nutrient salts are less than were found in the English Channel in the nineteen twenties but are not very different from the reduced quantities found there now. It is to be hoped that the investigations will be continued for a number of years to discover whether similar long-period fluctuations take place in Australian temperate waters, and further, that a well-found ship may be obtained to permit of investigations over a wider area unhandicapped by the difficulties of carrying on exact scientific work in the open ocean from the decks of a small yacht such as that at present in use.

Electricity Supply Tariffs

THE question of the standardization of electricity supply tariffs is of interest to many. A recent paper read by J. F. M. Mellor to the Students' Section of the Institution of Electrical Engineers on the basis on which those tariffs are founded is both a timely and a useful one. There are many difficulties in the way of getting an equitable solution to some of these problems. Take the case, for example, of an 'isolated consumer', that is, one who is at a considerable distance from the supply mains. In this case it is quite customary to charge the consumer the whole or part of the interest and depreciation on the capital cost of the mains extensions to his premises. It is reasonable, therefore, to expect that in the event of other consumers being connected on to these extensions, some refund should be made to the original consumer, and this should be mentioned in his agreement. The difficulty arises as to the period of time after the laying of the mains before the liability of the supply authority ceases. Another difficulty is that the time of the peak load varies owing to the great increase in domestic water heaters and thermal storage apparatus which has recently occurred. In many places, when making a long-term agreement, no period of the day or night can now be regarded as 'off peak' and allowed for at a cheaper rate. A supply for a fixed number of hours per day at the lower rate can be arranged, but this is not so attractive to the consumer. Everyone agrees that standardization is desirable, but there are difficulties in the way until the many small undertakings in the country are amalgamated with the larger authorities. When this comes, a lowering of the tariffs will follow in the country districts, since the 'diversity' of the combined load will be increased and so less spare plant be required. A broader policy also can be adopted.

Education of Unemployed in the United States

EDUCATIONAL needs of unemployed young people are discussed in Bulletin, 1936, No. 18–3, entitled "Education for those out of School", recently published by a standing committee established two years ago by the United States Office of Education in cooperation with other Government agencies and educational leaders for the purpose of assisting communities and youth agencies, with the aid of youths themselves, to solve some of the problems overshadowing their outlook to-day (Washington, D.C.: Government Printing Office, 1936. 10 cents). This pamphlet, the third of a series of six bulletins issued by the committee, describes some of the plans that have proved serviceable to unemployed persons of ages 16–24 years. Of the twenty million persons of those ages in the United States, some four million are in full-time schools and colleges, nearly eight million are employed on full- or part-time jobs, and nearly five million are seeking employment.

ONE conclusion arrived at by the committee is that there is a large unsatisfied demand on the part of these young people, and especially girls, for training which will lead to, if it is not combined with, earning capacity. Another conclusion is that in the case of rural youth a combination of educational and recreational schemes is essential; neither the strictly educational nor the strictly recreational schemes have been found successful. Again, informal rather than formal procedures are desirable, and units of instruction and courses should be of short duration; for example, twelve to fifteen weeks to a unit with two-hour meetings once or twice a week. Above all, instruction should have specific goals and arouse a sense of achievement or arrival at a determined destination, and work should be so planned as to give a sense of continuity. Particulars are given of numerous schemes of vocational training for out-of-school youth which have been found to work well. The other bulletins of this series are entitled: how communities can help, leisure for living, vocational guidance for those out of school, finding jobs, and health protection.

Scottish Technical Colleges

THE Royal Technical College, Glasgow, reviews, in its report on the work of the session 1935–36, its own progress since its constitution in 1886 by the amalgamation of Anderson's College with a number of other separate institutions. In these fifty years, the number of its day students has increased from 124 to 1,001 and its gross income from £9,248 to £81,837. Among its more important developments during that time are the establishment of departments of architecture, textile manufacture, navigation, sugar manufacture, pharmacy and bakery, and the erection and equipment of new buildings at a cost of £400,000. Its counterpart in Edinburgh, the Heriot-Watt College, has far fewer day students (364) but its evening class students (2,460) are nearly as many as those of the R.T.C. Both colleges co-operate with city and county education committees in regard to the provision in continuation schools of courses preparatory to college courses. The Edinburgh college, however, records a serious falling off in the number of students from city continuation schools, and attributes this decline to lack of interest on the part of employers.

Heat and Power Station in Northern Russsia

ACCORDING to the Soviet Union Year Book Press Service, Grand Buildings, Trafalgar Square, W.C.2, plans have been completed for the building of a large heat and power station about twenty miles from Kotlas, a busy town in the northern province of the U.S.S.R. It will be built in virgin forest, near the site where building work is now proceeding in connexion with cellulose, chemical and wood-working enterprises for the Soviet timber and paper industry. This year the first section of the station with a capacity of 24,000 kW. will be brought into operation. It will have an annual output of 1·2 million tons of steam. Fuel will be provided by gas generated by pitch, a by-product from the local timber and chemical industries. Four boilers will produce 60–80 tons of steam per hour, at a pressure of 35 atmospheres, the steam passing into turbines of 12,000 kW. each. These boilers are fitted with special fuel jets for the new form of fuel. The turbines can run at various steam pressures, depending on the requirements of production.

The Midwifery Service

THE annual report of the Central Midwives Board for the year ended March 31, 1936, has been published (London: H.M. Stationery Office. 2*d*. net). It shows that there were 62,064 women on the midwives roll, an increase of 3,100 on the total for the previous year, although only a little more than a quarter of the total number of qualified midwives are actually engaged in the practice of their profession. The report states that during the year the Board approved a final draft of new rules for training and examination, which has since been submitted to the Minister of Health. The report also includes notes on interesting decisions given by the Board during the year on midwifery etiquette and practice.

German Institute of Psychological Research

A GERMAN Institute of Psychological Research and Psychotherapy has been founded under the auspices of the German Home Office. The members consist of representatives of the Pan-German Medical Society of Psychotherapy, the German Psychoanalytic Society, the Künkel co-operative group for "Applied Study of Character" and other well-known psychotherapeutists. The functions of the Institute will be (1) research, (2) educational and teaching activities, and (3) maintenance of a clinic for the indigent. The director is Prof. M. G. Göring, president of the Pan-German Medical Society of General Psychotherapy.

Public Health Investigation in India

Two Indian institutes have recently issued their reports. That of the All-India Institute of Hygiene and Public Health, Calcutta, for 1935 reviews the courses of instruction that have been given and summarizes the research work carried out. The last-named includes epidemiological studies on cholera and studies upon the chemical constitution of the cholera vibrios by Dr. Linton, the epidemiology of epidemic dropsy and the ætiology of black-water fever. Diet surveys of certain sections of the population and field studies upon malaria have also been carried out. The second report, that of the Haffkine Institute, summarizes the Institute's work for 1932–35. Plague investigations have been continued, and more than two million doses of plague vaccine were issued in 1933–34; Drs. Sokhey and Maurice have prepared a curative plague serum which experimentally possesses greater potency than any sera previously prepared. Anti-rabic treatment is also provided at the Institute, and 2,274 cases were treated during 1935, with a mortality rate of 0·17 per cent.

Natural and Artificial Manures

THE Ministry of Agriculture has issued a new and enlarged edition of Bulletin 36, "Manures and Manuring" (H.M. Stationery Office, price 2*s*.). A number of additions have been made since the last issue, the preliminary section dealing with the principles that govern the manuring of farm crops having been specially expanded. As before, the bulletin is divided into three main sections, namely, organic manures, artificial fertilizers and the purchase and use of artificial manures. The information is essentially practical, and should enable the farmer to make the fullest use of the wide variety of fertilizers now available. In view of the differences in local conditions, complete generalizations are of course impossible, and in the event of uncertainty the farmer is advised to consult the agricultural organizer for the county in which he resides. A pamphlet (Form *A.* 705/*TG.*) giving names and addresses of advisory staffs may be obtained free on application to the Secretary of the Ministry of Agriculture, 10 Whitehall Place, London, S.W.1.

Broadcasting of Cosmic Data

A REGULAR schedule of broadcasts of cosmic data and scientific news was inaugurated at Boston, U.S.A., on February 1 by the World Wide Broadcasting Foundation's short-wave station in co-operation with the Union Radio Scientifique International and Science Service. The primary purpose of these broadcasts is to make available internationally technical data on observations of sunspots, solar radiation, magnetism, ionized layer heights and other phenomena observed during the same day, and to interest laymen in making observations. The broadcasts will be heard daily from 4.55 to 5.00 p.m. (Eastern Standard Time) on 25·4 metres and weekly summaries on Monday evenings from 8.30 until 8.45 p.m. on 49·6 metres. The Monday evening broadcasts will be a weekly compilation. The programme inaugurating this service included brief talks by Dr. A. E. Kennelly of Harvard University, the co-discoverer of the Kennelly-Heaviside layer; Dr. Harlow Shapley, director of the Harvard College Observatory, and Watson Davis, director of Science Service, Washington.

Science Abstracts

THE issue of the two index numbers of vols. 39 of *Science Abstracts* for 1936 enables a comparison to be made with previous volumes. The physics volume includes 5,716 abstracts covering 1,332 pages, with a subject index of nearly 260 and an author index of more than 80 pages. The electrical engineering volume has 3,525 abstracts in 820 pages, with subject index 120 and the author index 55 pages. The former volume is about six per cent larger than last year's and the latter about eleven per cent. The average length of the abstracts is slightly less than last year. The subject index in the physics volume has a key to it which facilitates its use. Each volume of *Science Abstracts* is a valuable time-saving device for those who wish to keep abreast of research or look up past progress in the subject with which it deals.

Prof. T. C. Hodson: a Correction

PROF. T. C. HODSON writes to point out in reference to the announcement of his impending retirement from the professorship of social anthropology in the University of Cambridge (see NATURE, March 20, p. 497), that he did not take a degree at Queen's College, Oxford, and that during the War, his service with the Indian forces covered a brief period only, when he was transferred to Railways and later to Forestry G.H.Q., where he took over from the late Lord Lovat. It should be added that Prof. Hodson was honorary secretary of the Royal Anthropological Institute in 1912–1914–15.

Comet Whipple (1937*b*)

USING observations made at Harvard on February 4, at Norwood on February 26 by Steavenson, and on March 11 and 12 by Hay at Hendon and Steavenson at Norwood, respectively, the Rev. Dr. M. Davidson has computed the following orbit: *T*, 1937

June 19·96971 U.T.; ω, 107° 25′ 56·0″; Ω, 127° 57′ 11·0″; i, 41° 43′ 31·7″; e, 1·009143; q, 1·739393. The orbit fits in with a number of other observations, but in many cases there are residuals of the order 1^s in right ascension. The object must be difficult to observe accurately as even on the same night discrepancies of about 1^s arise between different observers. Generally speaking, the residuals in declination are small.

Announcements

Sir Thomas Holland will deliver the Huxley Memorial Lecture in the Huxley Building of the Imperial College of Science and Technology, South Kensington, on May 4, at 5.30. The subject of Sir Thomas's lecture will be "The Permanence of Oceanic Depressions and Continental Elevations".

The George Darwin Lecture of the Royal Astronomical Society will be delivered by Prof. N. E. Nörlund at the ordinary meeting of the Society on May 14. His subject will be "Astronomical Longitude and Azimuth Determinations".

Dr. Simon Flexner, director of laboratories of the Rockefeller Institute, New York, has been elected a foreign associate of the Paris Academy of Sciences in succession to the late E. P. di Sessa.

Prof. Julius Wagner-Jauregg, professor of psychiatry and neurology at the University of Vienna and pioneer in the malarial treatment of general paralysis, celebrated his eightieth birthday on March 7.

A correspondent, writing with reference to the article in Nature of March 27 on the work of the Department of Scientific and Industrial Research, informs us the fundamental research on the setting of keratin (p. 535) in the manner used in 'permanent waving' is due to Dr. J. B. Speakman, of the Textile Department of the University of Leeds, and not to the Woollen Industries Research Association. In the first paragraph of the leading article of the same issue, the reference to Mr. D. R. H. Wilkins should have read Mr. D. R. H. Williams.

The Central Executive Committee of the U.S.S.R. has conferred the Order of Lenin on Prof. A. N. Bach, on the occasion of the fiftieth anniversary of his scientific activity, and for his outstanding services in the field of biochemistry. Prof. Bach celebrated his eightieth birthday on March 17. During his half-century of scientific research, he has published about 120 works, mostly dealing with problems of biochemistry. The three fundamental problems to which he devoted his energies were the chemistry of photosynthesis, respiration and enzyme action.

The National Trust announces that through the generosity of Mrs. Pollard, honorary secretary of the Cornwall branch of the Council for the Preservation of Rural England, the beautiful cliff lands extending for three quarters of a mile from Mulli[illegible] Porth Pyg about a mile and a quarter south of Mullion to the north end of Prodannack Head have been preserved by means of covenants in connexion with which part of the land will pass into the actual ownership of the Trust. The Tehidy Minerals Co., Ltd., has generously co-operated in regard to the mineral rights which it owned. The Trust will now be protecting eighteen coastal properties in Cornwall.

The forty-second Annual Congress of the South-Eastern Union of Scientific Societies will be held at Hastings on June 8–12, under the presidency of Prof. F. E. Weiss. The title of Prof. Weiss's address will be: "Competition and Co-operation in Nature." Further information can be obtained from the honorary general secretary, Mr. W. C. Fishlock, 19 South View Avenue, Reading.

Under the terms of the Thomas Gray Memorial Trust, the Royal Society of Arts is offering a prize of £75 to any person for an invention, publication, diagram, etc., which is considered to be an advancement in the science or practice of navigation; and a prize of £25 for an essay on "The Stability of Ships". Further information can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2.

A special Summer School and Conferences on Strength of Materials will be held at the Massachusetts Institute of Technology for four weeks beginning on June 21. The following subjects will be considered: creep (Dr. A. Nadai and Mr. C. R. Soderberg); fatigue (Dr. H. J. Gough); strength of materials (members of the Institute staff). Further particulars may be had by communicating with Prof. John M. Lessells, Department of Mechanical Engineering, Massachusetts Institute of Technology, who is director of this Summer School.

On April 30, a joint meeting of the Institute of Radio Engineers and the International Scientific Radio Union (American Section) will be held in Washington. A group of papers on the more fundamental scientific aspects of radio communication, including radio measurements, radio circuit theory, radio transmission phenomena including ionosphere phenomena will be presented. The meeting is open to the public. Further information can be obtained from R. C. Ould, 3747 Huntington Street, Washington, D.C.

The sixth Italian Congress of Microbiology will be held at the Milan Institute of Serotherapy on April 21–24. Further information can be obtained from Segretaria del Congresso, via Darwin 20, Milano 124.

The twenty-eighth Congress of the German Röntgen Society will be held in Breslau under the presidency of Prof. Pleikart Stumpf of Munich on April 12–14, when an exhibition of X-ray apparatus will also be held. Further information can be obtained [illegible] Elektromedizin, Corneliusstrasse 1,

Altitudes and Spectra of Red and Sunlit Auroras

As we approach the maximum activity of the sun, more and more interesting auroras occur. From my net of eight photographic stations in southern Norway, my assistants and I have in the last year got most interesting material, in particular from the auroras of April 20–21, 21–22 and October 16–17. On the two first nights, about 400 pictures were successful, among which is a series with the long base-line Oslo–Trondheim (391 km.). Of special interest were rays of sunlit auroras lying at the level 200–600 km. of the atmosphere, of which a spectrum on a panchromatic plate (Agfa *ISS*) was taken. This spectrum was measured by Mr. Harang, who found for the lines 6300 A., 5577 A. and 4278 A. the relative intensities 100, 100 and 55. A green aurora curtain gave, on the same plate and for the same lines, the intensities 32, 100 and 39. This enhancement of the red oxygen line was also observed for sunlit auroras by Currie and Edwards at Chesterfield during the polar year[1], by Kosirev and Eropkin at Kirowsk (March 1935)[2] and by Vegard and Tönsberg in October 1935[3] for the arcs of sunlit auroras. Flaming aurora was also observed which lay midway between Oslo and Trondheim. From both stations the motion was *upwards*, which showed that this really was the direction of motion of the auroral flames.

The aurora of October 16–17 last year was observed during 10 hours and more than 700 very successful pictures were taken from eight of my stations. The most conspicuous features were red auroras of long duration and sunlit aurora rays of quite unusual height. Of the first, 24 very successful sets were taken; of the second, 60 sets, all from two, three or four stations at the same time, simultaneously with 14 spectra, several of which are of unusual interest.

The first sunlit aurora rays in the morning appeared five hours before sunrise in the north-north-east and were photographed simultaneously from four stations, with maximum base-length of 159 km. The measurements of the plates showed that the rays were lying over Russia near Archangel. The lowest points were at the borderline between the sunlit and dark atmosphere at 600 km., and the summits reached the astonishing height of 1,100 km. above sea-level. The rays were red. Later, sunlit aurora rays of the common feeble grey-violet colour appeared and lasted until dawn. Several had their summits above 600 km., and some above 800 km., and the situation relative to the earth's shadow was similar to the diagram for March 23, 1920[4].

The red auroras were, with the above mentioned exception, all lying in the dark atmosphere, from 100 km. up to 500 km. over north-east[illegible] Scandinavia and Finland. Once I [illegible] rays which in a few sec[illegible] without altering their form and position, a phenomenon which I also saw on March 8, 1918[5].

The spectra were measured first by Mr. Harang and later by Mr. Björlykke. Details will be published later. The principal results were:

Agfa ISS Plates: For common *yellow-green arcs*, the two red lines 6550 A. and 6300 A. were nearly equal, and the aurora line 5577 A. about two to three times stronger than either of them. In the *red aurora*, the line 6550 A. was about 60 per cent of the aurora line, but the line 6300 A. was up to five times stronger. In the *sunlit feeble aurora rays* the line 6550 A. was more feeble than 5577 A. but the line 6300 A. about three times as strong[6].

Sonja Plates: In an *auroral arc* the intensity of the nitrogen bands 4278 A. and 3914 A. was about twice that of the aurora line 5577 A.; in the *sunlit aurora rays*, however, the intensity was increased to more than four times that of this line, an effect I had observed in 1929[7].

On January 7–8 this year, a new big aurora occurred and all my stations were in action the whole night. More than 700 good pictures were secured and a series of spectra. Among the pictures about 35 good sets were taken with the base-line Oslo–Trondheim. The results will be given later.

Acoustic Spectrum of Liquids

As is now well known, examination by means of a Fabry-Perot étalon reveals remarkable changes in the spectral character of monochromatic radiation when it is scattered within a dust-free liquid. Earlier studies in this laboratory[1] disclosed that the relative intensity of the undisplaced central line to that of the two Doppler-shifted companions appearing on either side of it varies greatly from liquid to liquid, being for example much larger in carbon tetrachloride than in toluene. The origin of the undisplaced central line has been until now one of the unsolved problems of the subject; its high intensity in the case of carbon tetrachloride and its practically complete polarization in this liquid as well as in toluene and carbon disulphide indicate that it cannot [illegible]ascribed to the depolarized scattering by optically [illegible]lecules.

Systematic studies have now been made with a number of liquids, including the following: acetone, carbon disulphide, toluene, water, formic acid, acetic acid, butyl alcohol, carbon tetrachloride, phenol and glycerine. The general result which emerges from this comparative study is illustrated in the accompanying Fabry-Perot patterns. Fig. 1 (*a*) is the Fabry-Perot pattern of the incident light, which is the 4358 A. radiation of a water-cooled low-density mercury arc lamp, while Fig. 1 (*b*), (*c*) and (*d*) are the patterns obtained respectively with the light scattered through 180° by the liquids phenol, butyl alcohol and acetone. It will be seen that the pattern given by phenol is indistinguishable from that of the incident radiation. A similar result has also been obtained with glycerine. With butyl alcohol, on the other hand, the Doppler-shifted companions are faintly visible, while with acetone, they are very conspicuous.

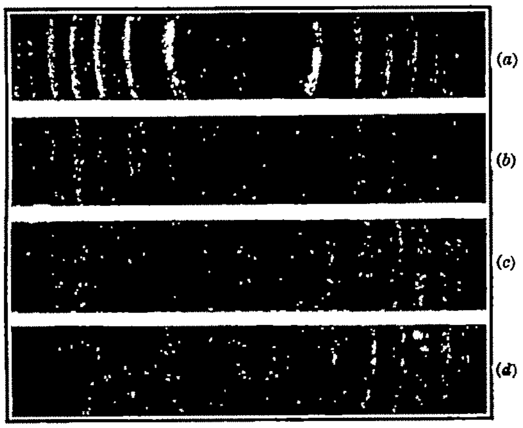

Fig. 1.

FABRY-PEROT PATTERNS OF INCIDENT RADIATION, 4358 A. (*a*), AND OF RADIATION SCATTERED BY PHENOL (*b*), BUTYL ALCOHOL (*c*) AND ACETONE (*d*).

It is thus seen that in highly viscous liquids such as phenol and glycerine, the sound waves of high frequency necessary for reflecting the incident light waves are conspicuously absent. The scattering of light within such liquids must therefore be ascribed to other causes, for example, relatively immobile fluctuations of density or clustering of molecules. The greater intensity of the Doppler-shifted components with such relatively inviscid liquids as acetone or toluene, on the other hand, indicates the existence in them of organized sound-waves as part of the thermal agitation. It appears reasonable to ascribe the unshifted central line obtained with such liquids to the existence of relatively immobile fluctuations of density or clusters of molecules on which the rapidly moving sound-waves are superposed. This is clearly suggested by the comparative study of the patterns obtained with various liquids, which indicates a progressive falling off in the intensity of the Doppler-shifted components with increased damping of high-frequency sound waves due to viscosity as given by the classical formula of hydrodynamics.

Ole Rømer's and Fahrenheit's Thermometers

IN my opinion, Dr. J. Newton Friend's recent article on "The Origin of Fahrenheit's Thermometric Scale"[1] contains some misunderstandings as to the nature of Ole Rømer's work on the thermometer, as will be shown in the following commentary.

Ole Rømer gives in "Adversaria" (printed in 1909) a detailed description of the construction of an "original thermometer" (that is, a standard thermometer) which was made about 1702 and filled with spirit. The particular feature of this thermometer lay in the principle according to which it was graduated, which made it possible to construct thermometers giving concordant readings, a problem which had not previously been solved. Rømer writes[2]: "When the thermometer is filled and closed, fix the point 7½ by means of snow or crushed ice, and the point 60 by means of boiling water". When these two points had been fixed, the volume between them was divided into 52½ equal parts, after which the zero point was determined by marking off 7½ parts of the same size below the freezing point.

It is therefore a misunderstanding of the facts when Dr. Newton Friend writes "Ole Rømer used this mixture" (ice and salt) "or a similar one (ice and sal-ammoniac) in obtaining his zero"; and "In checking his thermometer he used this temperature [the boiling point of water] and for convenience, possibly also for greater accuracy, the melting point of snow or crushed ice". This last statement is incorrect: the freezing point was the second fixed point, and was used as such, not "for convenience".

"Adversaria" contains no mention of any connexion between the zero of Rømer's thermometer and the temperature of a freezing mixture, and still less any statement that such a mixture was used for fixing the zero.

What then did Fahrenheit see and learn in Rømer's laboratory in 1708? He saw short thermometers for meteorological use graduated in such a way that they gave concordant measurements. According to Fahrenheit's description[3], this was done in the following way. The thermometers were first placed in melting ice and the position of the liquid in them marked. They were then placed in warm water—Fahrenheit calls it "blutwarm"—and the corresponding point marked and used as the second fixed point. One half of the distance between these two points was then marked out downwards from the freezing point to fix the zero (it is difficult to understand why Dr. Newton Friend writes, "How the zero was obtained is not definitely stated either in 'Adversaria' or in Fahrenheit's letter"), after which the distance between zero and the highest point was divided into 22½ equal parts. By means of this procedure 7½° came at the freezing point, and the temperatures 0° and 22½° bore the same relation to the freezing point as on the original (standard) thermometer. The temperature of the warm water *must* therefore have been 22½° Rømer (28·5° Centigrade), and not "blutwarm" as stated by Fahrenheit. The only way in which it could be ensured that the water actually had this temperature was by using the previously graduated standard thermometer, and the graduation of the latter by means of the two fixed points, *freezing point and boiling point*, was therefore also the basis for the graduation of Rømer's short thermometers.

After having seen Rømer's procedure, Fahrenheit understood the principle that the scales of thermometers giving concordant readings must be based on *two* fixed points, but he was less critical and less rational than Rømer in choosing these points. He retained the freezing point, measured in melting ice, as one fixed point, but he obviously wished to avoid the use of a standard thermometer for fixing the second. He had termed water of 22½° Rømer (28·5° C.) "blutwarm", and in this way conceived the idea of using a slightly higher temperature for the second fixed point, namely, body temperature measured "when the thermometer is placed in the mouth or arm-pit of a healthy man and held there until it acquires the temperature of the body"[4]. This temperature (about 36° C. or 26½° Rømer) is not particularly constant, and Fahrenheit therefore felt the need of a further fixed point as a check. It appears indirectly from a letter sent from Copenhagen to the Royal Society in 1709[5] that it had been discovered that the zero on Ole Rømer's thermometer "very nearly approaches the Point of Artificial Freezing". Fahrenheit must also have been aware of this, and therefore used the temperature of a freezing mixture for checking his zero. He admits that this temperature (like body temperature) is not quite constant, but his experimental skill enabled him to use the two not very reliable fixed points to check one another, and hence to make thermometers which were satisfactorily concordant according to the standards of the times.

The figures for the fixed points on Fahrenheit's earliest thermometers were:

0°; 7½°; 22½°; *as on Rømer's thermometers*, or 0°; 30° (= 4 × 7½°); 90° (= 4 × 22½°) by dividing the degrees into four parts. Later he altered these figures to

0°; 32° (= 4 × 8°); 96°, probably for convenience in calculation (as also suggested by Dr. Newton Friend).

Since the temperature 90° F. (corresponding to 26½° Rømer) is higher than Rømer's 4 × 22½°, Fahrenheit's degrees are larger than those of Rømer: hence if the graduation is continued in the same units, Fahrenheit's boiling point will be designated by a smaller number than Rømer's, namely, 212° instead of 240° (= 4 × 60°).

We thus see that Fahrenheit's scale is derived from that of Rømer. The honour of founding a great advance in temperature measurement is due to Rømer, but, like many of his other discoveries, it has passed unnoticed. Fahrenheit's skill in making thermometers enabled it to be put to general use, though in a somewhat incomplete form.

KIRSTINE MEYER (née BJERRUM).

Kildegaardsvej 12A,
Hellerup,
Denmark.

[1] NATURE, 139, 395 (1937).

[2] For a detailed review, see Kirstine Meyer, NATURE, 82, 296 (1910).

[3] Quoted from "Daniel Gabriel Fahrenheit", by Ernst Cohen and W. A. T. Cohen-De Meester. *Verhandl. der koninklijke Akademie van Wetenschappen te Amsterdam.* Afdeeling Natuurkunde, Deel XVI, No. 2. Amsterdam, 1931. The authors have translated the letter from Dutch to German.

[4] *Phil. Trans.*, 33, 73 (1724).

[5] *Phil. Trans.*, No. 324 (1709); cf. NATURE, 82, 297 (1910).

IN historical matters there is always room for divergence of opinion when the principals concerned, long since passed away, have left behind insufficient details to enable us to reconstruct the entire picture.

I am sorry that Dr. Kirstine Meyer does not accept my suggestion that Rømer's zero was obtained with a mixture of ice and salt (or sal ammoniac). We are all agreed that Rømer chose the boiling point of water as his upper fundamental fixed point and named it 60°. Dr. Meyer would have us believe that, as his lower fundamental fixed point, Rømer chose the temperature of melting ice, called it 7½° and evaluated his zero "by marking off 7½ parts of the same size below the freezing point".

I cannot believe that the great astronomer could be so inartistic as to choose arbitrarily the curious figure of 7½ for his lower fundamental fixed point. This number, however, ceases to be curious if the scale had already been fixed with reference to a zero whereby the temperature of melting ice became an *incident* on the scale and not its *origin*.

Are we to believe, with Dr. Meyer, that it is a pure coincidence that Rømer's zero corresponds to the eutectic temperature of ice and salt—a mixture that was already well known in Boyle's time? I think the paper in the *Phil. Trans.*, to which Dr. Meyer refers, will bear quite a different interpretation from that suggested by her.

Further, are we to assume that Fahrenheit, who copied Rømer's scale—not surreptitiously, for he openly acknowledged it—and Rømer's methods in their entirety, did not also copy the method of obtaining his zero from Rømer?

Piecing all these points together, it appears to me that the balance of evidence distinctly favours the view expressed in my article, and I am extremely sorry to have to join issue with so great and well known an authority on Danish thermometry as Dr. Kirstine Meyer.

Having once devised his scale, there was nothing to prevent Rømer from preparing standard thermometers as described in "Adversaria", using as *control* points 60° and 7½° respectively. This is what one would expect, for the construction of a standard thermometer would naturally follow, rather than precede, the selection of the scale. Once the scale had been selected, any suitable control points could be used, as at the present time, in the graduation of standard instruments. Dr. Meyer has clearly confused this latter operation, as described in "Adversaria", with the invention of the scale itself, which is not described either in "Adversaria" or anywhere else so far as we know. Hence my suggestion as to its probable origin, and my statement which Dr. Meyer finds "difficult to understand".

I am sorry that Dr. Meyer is so critical of Fahrenheit's part, for Denmark owes much to Fahrenheit; without him Rømer's scale would undoubtedly have sunk into oblivion like that of Newton. Newton's scale was a much more convenient one and antedated Rømer's by at least a year; but Newton had no Fahrenheit to commercialize his thermometers and thus bring his scale into common use.

Personally, I wish Rømer's scale had also remained a historical curiosity and that the centigrade scale alone had survived. It would have saved much inconvenience to many of us.

Bleaching of Visual Purple in Solution

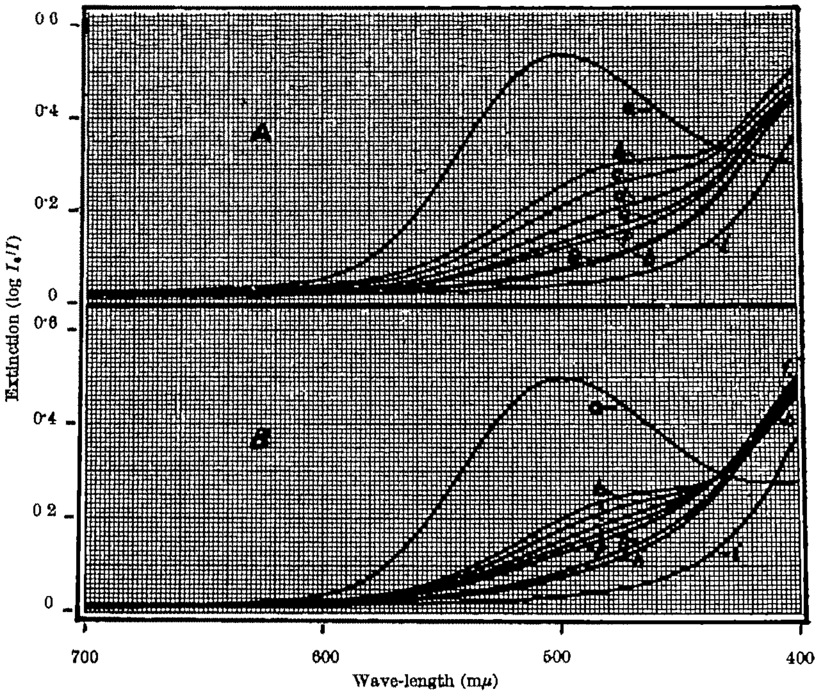
A NEUTRAL solution of visual purple exposed to bright light bleaches almost instantly to a deep orange colour, then more slowly to pale yellow. This transition has been believed to be wholly photochemical; the orange material a mixture of unbleached visual purple with the final yellow residue[1]. Both assumptions are mistaken: the orange photo-product is new pigment, which fades to yellow in complete darkness.

I have examined these processes with a recording photo-electric spectrophotometer[2], with which complete spectra were registered within two minutes, and in the case of visual purple could be completely retraced without perceptible bleaching.

Visual purple solutions from marine fishes (scup, sea robin, sea bass, killifish), summer and winter frogs, rabbits and rats behaved identically in these experiments. Typical data obtained with bull frog visual purple in 1 per cent aqueous digitonin, buffered at *p*H 6·9, are shown in Fig. 1. Half the preparation was measured four hours after extraction (*A*), the remainder one week later (*B*). The curves show the spectra of whole extracts, measured against an equal depth of distilled water.

The original solutions possess a single broad absorption band, maximal at 500 mμ (curves *a*). They were exposed for ½ minute to bright light (700 ft. cdles.) and the spectra immediately re-measured (curves *b*). The orange-coloured photo-product possesses a broad absorption band maximal at about 480 mμ, and higher absorption than visual purple itself below 430 mμ.

The solutions were left in position in complete darkness, and their spectra periodically re-measured, curves *b* at 1·2 minutes, *c* at 3·2 and 3·7, *d* at 7·2 and 8, *e* at 13·8 and 15·7, and *f* at 32·2 and 32·8 minutes (29·3° C.). (Times are from the beginning of irradiation to the recording or the extinction at 500 mμ. When two times are given, the first refers to *A*.)



At 35 minutes the preparations were re-irradiated as before for 40 seconds and their spectra recorded (curves *g*, 37 minutes). At 38·5 minutes they were exposed for a third time, and yielded curves *h* (40 minutes). Curves *f* to *h* show the bleaching of a small amount of visual purple, probably re-generated during the period in darkness[3].

Of the total fall in extinction from curves *a* to *f*, 31 per cent at 500 mμ and 42 per cent at 480 mμ are due to 'dark' processes. These may in turn be analysed into two components. One, a slow, general fall in the entire 'bleached' spectrum was discovered by Hosoya[4]. I have found it to appear clearly only in fresh preparations. It is prominent in *A*, recorded several hours after extraction, but has vanished completely from this preparation after a week's storage (*B*). The second 'dark' component, shown isolated in *B*, rapidly obliterates the initial 'bleached' maximum at 480 mμ, with simultaneous rise in absorption below 435 mμ. This is an invariable element of the bleaching of neutral visual purple solutions. In *B* it alone accounts for 19 per cent of the fall in extinction from curves *a* to *f* at 500 mμ, and 26 per cent of that at 480 mμ.

The final product of bleaching (curves *h*) is a relatively stable yellow material, the spectrum of which is slightly inflected at 405–410 mμ, and which absorbs more strongly than visual purple itself below 420–430 mμ.

Chase[5] has observed striking differences in the course of bleaching at various *p*H's. I find these to depend principally upon changes in the 'dark' components. In acid solution (*p*H 3·9) the initial photo-product possesses an almost symmetrical absorption maximum at about 440 mμ, which progresses slowly in light or darkness into the ultra-violet, leaving finally only the terminal absorption of a stable, deep yellow end-product. With decrease in acidity the 'dark' processes accelerate greatly. At *p*H 10·5 no 'dark' reaction has yet been detected, presumably because it is too rapid for measurement; irradiation yields almost immediately a stable, very light yellow material, the absorption of which still rises above that of visual purple below 410 mμ. The final product is really the same at all *p*H's; its colour varies reversibly with *p*H[5].

Under all known conditions, therefore, visual purple bleaches to new pigments. At 400 mμ, increases in absorption, the reverse of bleaching, are invariably observed. The common representation of the visual purple spectrum as the difference in absorption between unbleached and bleached preparations[6] is therefore physically meaningless.

The final yellow residue, extracted with benzine containing 1 per cent ethanol, yields all colour to the benzine. The yellow pigment, returned to buffered aqueous digitonin solution, possesses a spectrum similar to that of the whole 'bleached' residue (curves *i*). It exhibits the same *p*H colour changes as the entire residue. In chloroform, tested with antimony trichloride, it yields the deep blue colour and sharp absorption band at 664 mμ characteristic of retinene[7]. Though in the retina retinene is involved in further changes[7], it is the final product of bleaching in solution.

A New Blood Pigment: Pseudo-Methæmoglobin

IN addition to oxyhæmoglobin, methæmoglobin has been recorded in the plasma of blackwater fever patients by Arkwright and Lepper[1], Yorke, Murgatroyd and Owen[2], Ross[3] and Fairley and Bromfield[4]. In 1934 the latter observers[5] described an unnamed pigment closely allied to methæmoglobin in a case of blackwater fever. Spectroscopically it resembled methæmoglobin, but did not reduce with Stokes's reagent or ammonium sulphide. It produced a chocolate-coloured blood, a brown-coloured plasma, was absent from washed corpuscles and failed to appear in the urine. Specimens of plasma were sent to Prof. D. Keilin, who suggested that the pigment originated as some modification of methæmoglobin in which the globin portion of the molecule had undergone an irreversible change. The following year the same pigment was again encountered in this disease, and recently R. J. Bromfield and I went to investigate this question at the Malaria Laboratory of the League of Nations, Salonika.

Blood Pigments in Macedonian Cases of Blackwater Fever

As a routine procedure, the plasma and urine were examined on a Hartridge spectroscope set against artificially produced methæmoglobin, and the effects of treatment with Stokes's reagent, ammonium sulphide (10 per cent) and hydrogen peroxide (10 vols.) were noted. All these reagents disperse the α band of true methæmoglobin, but not that of the new pigment. Fourteen cases were investigated. The plasma contained oxyhæmoglobin alone in two mild cases, new pigment alone in two severe cases seen on the third and sixth days respectively, and new pigment and oxyhæmoglobin in the remaining ten. In not a single instance was methæmoglobin demonstrated.

The urine, on the other hand, never contained new pigment in demonstrable quantity. Oxyhæmoglobin was found alone in two instances and in association with methæmoglobin in ten others; in the two remaining cases the urine contained no blood pigments, though new pigment was demonstrated in the plasma. All the available data indicated that the new pigment did not traverse the glomerulus, and that urinary methæmoglobin was derived from oxyhæmoglobin during or after its passage through the tubules. Microscopic examination of the kidneys showed that the formation of new pigment protects them from the pathological effects induced by the renal excretion of hæmoglobin.

Finally, in a series of spectrograms taken for us by H. Foy, the centre of the α band of the pigment in the plasma always approximated to 6240 A., whereas that of the urine was constantly about 6300 A. Evidence regarding the duality of these pigments was thus complete.

Production of Pseudo-methæmoglobin in Vitro

The formation of methæmoglobin in sterile blood or hæmoglobin solution stored under ordinary conditions or after incubation at 37°–55° C. has long been recognized. To ascertain whether the new pigment could be produced *in vitro*, plasma from blackwater fever patients was incubated at 37°–40° C. for 48 hours with a concentrated solution of hæmoglobin prepared from laked corpuscles. The new pigment invariably resulted. But in controls, using normal plasma, we were surprised to find that the new pigment, and not methæmoglobin, appeared. The new pigment was also formed from a solution of methæmoglobin prepared by treating laked corpuscles with potassium ferricyanide when it was incubated with plasma at 37°–40° C. for 48 hours. The incubation of unlysed corpuscles and plasma produced neither methæmoglobin nor new pigment, while on incubating a solution of hæmoglobin alone, methæmoglobin formed.

These experiments prove that plasma has the power of converting extra-corpuscular hæmoglobin or methæmoglobin into the new pigment when incubated under appropriate conditions, and suggest that in any severe intravascular hæmolysis it is this new pigment, and not methæmoglobin, which is formed. Since 1864, when Hoppe-Seyler[6] first described methæmoglobin, this allied pigment has escaped recognition, and for this reason the name pseudomethæmoglobin appears to be a not inappropriate one.

Effect of Testosterone Propionate on Mating

MUCH has been written recently about the effectiveness of testosterone in restoring the atrophic accessory glands of castrated rats, but little, if any, attention has been paid to its effect on mating behaviour.

Five rats were castrated at 30–50 gm. body weight, that is, well before sexual behaviour begins, and were kept isolated for nine weeks, when they were put with normal females. They showed no sexual behaviour. The following day they were again isolated and a course of eighteen daily injections of 0·5 mgm. testosterone propionate ("Perandren" Ciba) was begun. Development and hyperæmia of the penis was evident within a week of the beginning of treatment. Females were put into the cage eight days after the beginning of the injections and attempts at mating were observed. Two vaginal plugs, indicating that two males had mated and that their seminal vesicles and prostate were well developed, were found next day. After twelve days' treatment, the five males were separated and each given five females. Within five days all the males had mated (as determined by the occurrence of vaginal plugs), one of them repeatedly.

Prepubertally castrated male rats are not known to mate. They would in any case be unable to leave vaginal plugs, so that the results described above must have been due to the treatment with the testosterone propionate, which stimulated the development of the penis and the secretory activity of the accessory glands and induced mating behaviour. Since removal of the seminal vesicles and the prostate of normal rats does not eliminate the mating reflex[1], the appearance of this reflex is not likely to be a mechanical effect due to distension of the glands.

Stimulating Materials obtained from Injured and Killed Cells

PREVIOUS work of ourselves[1] and others[2] has shown that ultra-violet radiation appears at times to stimulate cell division in micro-organisms, but that there is little consistency in obtaining the effect. To establish whether or not stimulation of metabolic processes occurs when cells are subjected to lethal ultra-violet irradiation, the respiration of yeast suspensions irradiated with full ultra-violet under various conditions was compared with that of controls. Again inconsistent results were obtained, but definite stimulation occurred in a number of cases. There then followed an investigation of various factors, such as *p*H, age of organisms, quality and quantity of radiation, etc., which might have accounted for the inconsistencies.

The results of these investigations suggested that the apparent stimulation of respiration might be caused by materials from the injured or killed cells which affected surrounding cells, and that the depression observed in many cases was the result of the killing of so many cells in the irradiated suspensions that too few were left to produce a respiratory effect equal to that of the control. To test this hypothesis, cells irradiated until they no longer respired were added to non-irradiated cells. Under these conditions, stimulation was uniformly obtained.

Following these results, suspensions of yeast were irradiated for a sufficient time to kill all the cells present, the suspensions were centrifuged and filtered through a Seitz bacterial filter, and the cell-free fraction and remaining dead cells added to separate suspensions of normal cells. The dead cells caused an average increase of about ten per cent in respiration (in terms of the technique used), while the cell-free extract produced an average increase of about fifty per cent. Further studies showed that cell-free extracts from cells injured or killed by X-rays, heat, or mechanical injury gave comparable results. The effect was not confined to micro-organisms—cell-free extracts from irradiated liver, kidney and embryo tissues, etc., also showed it.

Studies of the proliferation-promoting power and fermentation stimulation of some of the extracts were made, using yeast as a test organism. Definite stimulation was obtained in all cases. The preliminary results obtained thus far indicate that materials from different sources, prepared in different ways, show different orders of potency with regard to stimulation of respiration, proliferation and fermentation, suggesting the existence of at least three substances responsible for the effects. Some preparations were subjected to dialysis. The active materials passed through the dialyzing membrane, leaving inactive residues behind.

Experiments are under way with cell-free fractions, prepared by different methods from micro-organisms and tissues of various kinds, in which parallel respiration, proliferation and fermentation tests are being compared with the ultra-violet absorption spectra of the concentrates with the view of elucidating the chemical nature of the active components. Some of the materials resemble in their biological properties bios preparations from yeast and malt combings. The spectra, however, indicate wide variation in the chemical nature of the substances present. Which of the compounds the presence of which is indicated by the spectra are active materials and which are impurities remains to be determined. Some of the spectra show the presence of large quantities of nuclear purines and pyrimidines, the relation of which to the lethal action of the ultra-violet has already been noted[3].

We are particularly interested in the possible relation of these materials to the mechanism of tissue repair after injury and to the mechanism of malignant growth.

Electrical Conductivity of a Supraconducting Sphere in the Intermediate State

A SPHERICAL single crystal of tin was placed in a magnetic field at a temperature below T_k. The electrical conductivity was determined (by measuring the current in a supraconducting circuit) for various directions of the current with regard to the magnetic field. It was found that the sphere remained supraconducting in the direction of the field up to field-strengths very nearly equal to H_k. In the direction perpendicular to the field, supraconductivity vanishes at field strengths near $2/3\ H_k$. In other directions supraconductivity is destroyed in the interval of field-strength between $2/3\ H_k$ and H_k.

It is well known that for a supraconducting sphere at field-strengths greater than 2/3 H_k the magnetic permeability μ is no longer equal to zero, while macroscopic measurements show that the sphere is magnetized homogeneously[1]. Peierls[2] named this the 'intermediate state' and assumed it to consist of supraconducting and normal regions. Landau[3] calculated that these regions have a definite structure and orientation depending on the external field and the field caused by the current.

Our experiments show that in the intermediate state the sphere possesses anisotropic supraconductivity and, when the direction of the current is parallel to the external field, can remain supraconductive right up to the field strength H_k, that is, even when μ is very near to unity.

A detailed report will be published shortly in *Sow. Phys.*

Band Spectrum of Manganese Hydride, MnH

FOLLOWING on previous work in which we observed the spectrum of nickel hydride[1], NiH, in a high-tension arc between nickel electrodes in a flame of hydrogen burning in air, we have made similar experiments with other metals. With manganese, four bands with open rotational structure have been observed. The strongest band is in the yellow-green; it is degraded to the violet, and shows a rather complicated rotational structure; there is a strong head at λ 5678, and a fainter one at λ 5722. Bands in the green (heads at λ 5172 and λ 5205) and red (head at λ 6240) have a rather similar appearance, and the three bands may be considered tentatively as the (1,0), (0,0) and (0,1) bands of the same system. There is also a band in the blue; this is degraded to the red and has a simpler rotational structure than the other bands; its head is at about 4500 A.

The spectrum has also been produced in a discharge tube; in this the bands are rather masked by the molecular spectrum of hydrogen, but their production in this source, which does not contain oxygen or nitrogen, strengthens the assignment of the bands to MnH. (Feb. 24.)

Since writing the above, our attention has been attracted to a note on the spectrum of manganese hydride by T. Heimer[2], who has already recorded the three bands in the red, yellow-green and green which we described, and has made the same assignment of vibrational quantum numbers. In the blue, the very close band structure in the region 4700–4850 A. which Heimer records is not the structure which we described. The latter is much more open and forms a head at λ 4500. Further scrutiny of our plates shows that the band obtained by Heimer is also present. On the more strongly exposed plates the two structures run into one another and are possibly closely related.

The manganese atom has as its ground state the configuration

$$1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 4s^2 \qquad {}^6S,$$

and it therefore seems likely that in the formation of MnH the ground-level will be either ${}^5\Sigma$ or ${}^7\Sigma$. If the rule of Heitler and London is obeyed, then only the ${}^5\Sigma$ level will be stable. Transitions involving a change of multiplicity do not produce strong band systems, and hence the only probable transitions are ${}^5\Sigma \rightarrow {}^5\Sigma$ and ${}^5\Pi \rightarrow {}^5\Sigma$. The bands in the yellow-green and blue, as seen on our spectrogram taken in the first order of a 20 ft. concave grating, appear to be too complicated for the first alternative, and the presence of branches of Q form favours a ${}^5\Pi \rightarrow {}^5\Sigma$ transition.

The lowest four terms of the Mn atom (excluding the ground state) are ${}^6D$, ${}^4P$, ${}^8P$ and ${}^6P$. The ${}^6D$ term could produce a ${}^5\Pi$ level for MnH, but since the change to the ground level requires that a $3d$ electron should be promoted to the $4s$ shell, this change seems improbable. Both the ${}^6P$ terms could, however, give ${}^5\Pi$ levels, and it seems likely that this is the case, one producing the system of bands in the yellow-green, and the other the blue band.

Spectrum of Mercury Chloride (HgCl) and Samuel's Theory of Linkage

ACCORDING to Samuel and co-workers[1], atoms of the second group of the Periodic System are chemically inert in their helium-like ground term ${}^1S$. Linkage becomes possible only in an excited atomic term. Among many diatomic molecules (oxides and chlorides) of this group, cadmium fluoride (CdF), from its emission bands[2], is claimed to be a very conclusive example of this kind of linkage. Other investigations on the spectra of the diatomic halides of mercury, cadmium and zinc[3,4], however, make it probable that the ground state of these molecules is built up from unexcited atoms.

On this point, I would refer to a hitherto not analysed spectrum of diatomic mercurous chloride (HgCl) vapour, stretching from λ 5600 A. to λ 3200 A. This well-known spectrum, if excited in a Geissler discharge, consists of an enormous confusion of bands and is, therefore, unsuitable for analysis. If excited by fluorescence, however, that is, by optical dissociation of triatomic mercuric chloride ($HgCl_2$) vapour with light shorter than λ 1900 A., the spectrum shows a much simpler band structure. Almost all the bands (more than a hundred in number) which appear in fluorescence and are degraded towards the red, fit very well into the following vibrational equation:

$$\text{I.}\ \left.\begin{matrix} v' = 0,\ 1,\ ..33 \\ v'' = 0,\ 1,\ ..11 \end{matrix}\right\} \quad \nu = 23372 + \left.\begin{matrix} (191{\cdot}5\ v' - 0{\cdot}50\ v'^2) \\ -\ (291{\cdot}9\ v'' - 1{\cdot}875\ v''^2) \end{matrix}\right\}\ \text{I}$$

$$\text{II.}\ \left.\begin{matrix} v' = 33,34,..\ 50 \\ v'' = 11,12,..25 \end{matrix}\right\} \quad \nu = 23372 + \left.\begin{matrix} (181{\cdot}75\ v' - 0{\cdot}35\ v'^2 + 159) \\ -\ (301{\cdot}85\ v'' - 2{\cdot}35\ v''^2 + 52) \end{matrix}\right\}\ \text{II}$$

The lower electronic state (v'') is identical with the ground state known from an ultra-violet band system of HgCl[4]. A rather sudden change of the anharmonicity occurring at high quantum numbers (at $v' = 33$ and at $v'' = 11$)—also observed in the band spectra of oxygen[5] and of chlorine[6]—makes it preferable to use two quadratic formula instead of a single cubic one. Formula I will be used for the evaluation of the zero band ν_0 and of the ground frequency; formula II for the calculation of the dissociation energies D' and D''. Thus we obtain (in electron volts):

$$\nu_0 = 2{\cdot}88 \text{ volts}, \; D' = 2{\cdot}91 \text{ volts}, \; D'' = 1{\cdot}20 \text{ volts},$$

and, from that, the atomic term $\nu_a = \nu_0 + D' - D'' =$ 4·6 volts, a value equal to the term difference $2^3P_0 - 1^1S$ (4·65 volts) of the mercury atom. This remarkable agreement supports strongly the assumption that the ground state of the HgCl molecule is built up from a Hg atom in its lowest term (1^1S)—and not from an excited one—and from a Cl atom also in its normal term. The same will presumably hold for the other diatomic iodides, bromides and chlorides of mercury, cadmium and zinc, the spectra of which are very similar to the spectrum of HgCl. Further work is needed to confirm that and to ascertain whether the fluorides of these metals behave in a different manner.

Experiments on the spectra of HgBr and HgI are in progress.

Gold Deuteride Bands

AN arc between gold poles in heavy hydrogen gas of high concentration at a pressure of about 12 cm. mercury was photographed in the second order of a 15-ft. concave grating. 723 AuD lines lying between λ 3370 A. and λ 4440 A. were analysed into eleven bands of a $^1\Sigma \rightarrow {}^1\Sigma$ system as, 2 → 0 (λ 3382), 1 → 0 (3502), 2 → 1 (3585), 0 → 0 (3646), 2 → 2 (3775), 0 → 1 (3872), 1 → 2 (3935), 2 → 3 (4005), 0 → 2 (4117), 1 → 3 (4183) and 0 → 3 (4384) vibrational transitions. The 1 → 1 band was of such low intensity that no single line of it could be identified.

Preliminary evaluation of molecular constants, based on the rotational energy function ending in the $J^2(J+1)^2$ term for both the $^1\Sigma$ states, and adjusted for the region of $J = 6 \sim 10$ to $J = 30 \sim 35$ in each vibrational level, has yielded the values given in the accompanying table, with calculated probable errors for the rotational constants.

MOLECULAR CONSTANTS OF AuD

	Lower $^1\Sigma$ state	Upper $^1\Sigma$ state
T_e	0	27644·1
ω_e	1634·98	1195·24
$x_e\omega_e$	21·66	34·81
$y_e\omega_e$	−0·0288	——
B_e	3·6413 ± 0·00008	3·041 ± 0·003
α	0·07608 ± 0·00002	0·1075 ± 0·001
D_e	$-0{\cdot}7090 \times 10^{-4} \pm 0{\cdot}0002 \times 10^{-4}$	$-0{\cdot}79 \times 10^{-4} \pm 0{\cdot}01 \times 10^{-4}$
β	$3{\cdot}36 \times 10^{-7} \pm 0{\cdot}04 \times 10^{-7}$	$-6{\cdot}2 \times 10^{-6} \pm 0{\cdot}4 \times 10^{-6}$

D_v of the upper $^1\Sigma$ state *decreases* with v in a markedly non-linear way, but as only three vibrational levels are found in this state, the most probable values of D_e' and β' for the linear formula are provisionally given in the table.

The electronic isotope shift from the corresponding AuH system (0 → 0, λ 3650 A.) is + 14 cm.$^{-1}$. Other isotope relations between the constants of the two molecules will be considered in a coming number of the Institute's publication (*S.P.I.P.C.R.*), together with frequency tables and other details of the observed deuteride bands.

Correlation of Ionization Constants of Organic Acids with Dipole Moments

SINCE ionization constants and dipole moments are both measures of polarity, it is logical to suppose that a connexion will exist between them. Interesting results have followed an examination of the elementary possibility that the difference between the strengths of substituted and unsubstituted acids in the benzoic and phenylacetic series, and the dipole moments of monosubstituted benzenes (virtually the substituent groups), are simply related. The ionization constant values (K_{therm}) were all derived in this Department and the dipole moments were those employed by Dippy and Watson[1] in connexion with the logarithmic relationship observed previously. These sets of data possess the advantage of being comparable.

In the benzoic series the points representing *m*-nitro-, *m*-methoxy-, unsubstituted and *p*-methyl-substituted acids are distinctly colinear. A second straight line of much smaller angle can also be drawn through *m*-nitro-, *m*-chloro, *m*-iodo-, unsubstituted and *p*-methyl phenylacetic acids. In the benzoic acids the *m*-halogens show a small disparity (cf. Dippy and Watson[1]) but the abnormality has been so diminished in the phenylacetic acids that it is not distinguishable. The inclusion of the *p*-methyl acids, and not the *m*-acids, as at first expected, is especially important, and it must mean that the polar effect of the methyl group measured in toluene, is the effect of a *p*-methyl substituent, that is, the two permanent components (the inductive and mesomeric effects) are operative.

A fuller account of this relationship, accompanied by figures, will be published shortly.

Electron Inertia as the Cause of Harmonics in Valves

THE Lagrangian form[1] of Benham's equation[2], connecting the total current density with the rate of change of acceleration of particles of charge e, mass m, moving in a one-dimensional, non-uniform* electric field, may be written, for electrons,

$$\dddot{x} = 2{\cdot}00_2 \times 10^{26} i \quad . \quad . \quad . \quad . \quad (1)$$

in which the numerical value of $\frac{4}{10}\pi\frac{e}{m}c^2$ is in dynes coulomb^{-1} gm.$^{-1}$ and i is in amp. cm.$^{-2}$. The electric field, which may vary with time in any manner, is proportional to $\ddot{x}$. Omitting the constant, and writing $q = \int i dt$, we obtain from (1), on integration over the interval $(t - t_0)$:

$$\ddot{x} = \ddot{x}_0 + q(t) - q(t_0) \quad . \quad . \quad . \quad . \quad (2)$$

---

* The non-uniformity is caused only by the electrons themselves.

By differentiating equation (2) with respect to time at x constant, we find :

$$\left.\frac{\partial \ddot{x}}{\partial t}\right|_x = \left.\frac{\partial \dot{x}_0}{\partial t}\right|_x + i(t) - i(t_0)\left.\frac{\partial t_0}{\partial t}\right|_x$$

$$= \left[\frac{\partial \ddot{x}_0}{\partial t_0} - i(t_0)\right]\frac{\partial t_0}{\partial t} + i(t) \quad . \; . \; . \quad (3)$$

Equation (3) shows that the quantity $i(t) - \frac{\partial \ddot{x}}{\partial t}$ is related to its value at the plane $x = 0$ $(t - t_0)$ seconds earlier by the relation

$$i_c(x,t) = i_c(0,t_0)\left.\frac{\partial t_0}{\partial t}\right|_x , \quad . \; . \; . \; . \; . \quad (4)$$

(where $i_c(x,t)$ has been written for the quantity $i(t) - \frac{\partial \dot{x}}{\partial t}$, and clearly represents the electron convection current. If we perform three integrations of equation (1), we obtain the position x of a particle which started with a velocity $\dot{x}_0$ and acceleration $\ddot{x}_0$ at instant t_0 and travelled over the distance x in the interval $(t - t_0)$. This expression may then be differentiated with respect to t, keeping x constant. For a total current of the general form $\sum_{n=0}^{n=\infty} i_n e^{npt}0$, (where p may be complex in general), the value of the electron convection current ratio $\left.\frac{\partial t_0}{\partial t}\right|_x$ is then found to be as follows (5):)

$$\frac{\dot{x}_0 + \ddot{x}_0(t-t_0) + \sum_{n=0}^{n=\infty}\frac{i_n}{(np)^2}\left\{e^{npt} - e^{npt_0} - np(t-t_0)\,e^{npt_0}\right\}}{\dot{x}_0 + \ddot{x}_0(t-t_0) - (t-t_0)\left.\frac{\partial \dot{x}_0}{\partial t_0}\right| + \frac{1}{2}(t-t_0)^2\left\{\sum_{n=0}^{n=\infty} i_n e^{npt_0} - \frac{\partial \ddot{x}_0}{\partial t_0}\right\}}$$

The term $\left\{\sum_{n=0}^{n=\infty} i_n e^{npt_0} - \frac{\partial \ddot{x}_0}{\partial t_0}\right\}$ represents in all circumstances the electron convection current $i_c(0,t_0)$. In the space charge limited diode, the terms in $\dot{x}_0, \ddot{x}_0$ may be omitted without great error from the expression (5), provided the total transit time is not less than 4×10^{-10} seconds for a total current density of 100 in mA.cm.$^{-2}$. Then

$$i_c(x,t) = \sum_{n=0}^{n=\infty} i_n . \Upsilon_2(n\alpha) . e^{npt}, \quad . \; . \; . \quad (6)$$

where $\Upsilon_2(\zeta) = \frac{2}{\zeta^2}\left\{1 - e^{-\zeta} - \zeta e^{-\zeta}\right\}$ and $\alpha = p(t - t_0)$.

In order to see the significance of this result, let us suppose the total current to consist of zero and first order terms only. Then equation (6) reduces to

$$i_c(x,t) = i_0 + \underset{\longrightarrow}{\underline{i_1 \Upsilon_2(\alpha) e^{pt}}} \quad . \; . \; . \; . \quad (6a)$$

The arrow means that the term in question is not a pure sinesoid in view of variations in the value of $\frac{\alpha}{p}$ $(= t - t_0)$ about a mean value. Higher harmonics are thus contributed by the underlined term. The fundamental is obtained by writing $\alpha = \alpha_0$ in (6a), which gives the usual solution without reference to the ripple α_1. Similarly, the second order term is obtainable without reference to the ripple α_2 but requires the ripple α_1 to be known in addition to α_0.

Thus, not only has a considerable simplification been introduced into the calculation of the fundamental component, but also, by the present analysis, the calculation of second, third and even fourth harmonics of potential is made possible[3]. I have completed the accurate calculation of the second harmonic in the space charge and emission limited plane diodes, and I hope to make these available in the near future.

Phosphorescence of the Sea

THE well-authenticated phenomenon of streaks of phosphorescent water appearing in the sea[1] is doubtless due, in some way or other, to the agitation of phosphorescent marine organisms. In the past it has been ascribed, either to the effect of long rollers[2] or less commonly to porpoises[3] or schools of fish below the surface[4].

W. Schmidt's[5] observations on the so-called 'oil-patches' on water surfaces suggest a new interpretation. Under the influence of wind, a water surface divides itself up into ascending and descending areas, in the latter of which all small floating bodies collect. In lakes the descending areas often take the shape of long streaks, although there is no reason why other forms should not occur in the open sea.

If, therefore, luminous organisms collect in the descending areas, streaks of light might occasionally be formed. That the observed lines of phosphorescent water are at least occasionally formed in this way seems to follow from the fact that they have sometimes been observed to coincide with areas in which the water is especially calm. Thus L. C. Higgins[6] (South Atlantic. July 5, 1926) reported five bands stretching across the water "as far as eye could see" and added : "The phosphorescence seemed to make the sea thick and sluggish." Similarly, H. A. Standfeld[7] (China Sea, April 24, 1928) reported six streaks and remarked : "It was also noticed that the streak had an oily appearance on the surface of the water."

A similar interpretation is probably to be placed on the large patches of luminous water covering a few hundred square yards which have been recorded repeatedly. In a recent description by W. J. V. Branch[8], they have been stated to exert a calming effect comparable with that of light oils on water.

If this interpretation should be confirmed, observations on the shapes and sizes of phosphorescent marine areas should serve to throw light on the vertical movements of sea water.

Occurrence of *Eucrangonyx gracilis*

IN NATURE of February 20, there appeared an interesting letter from Mr. G. I. Crawford recording the amphipod, *Eucrangonyx gracilis*, from the filter beds of the Metropolitan Water Board at the Lea Bridge Works.

It may be of interest to record that some years ago I received from Dr. Robert Gurney, of Oxford, an amphipod which was found in a glass of water drawn from the domestic supply of a house in Hackney. The only species with which I could identify the specimen was *Eucrangonyx gracilis*, but the occurrence appeared to me to be so unusual and puzzling that I refrained from recording the species pending confirmatory evidence in the shape of more material. It was impossible to trace the householder who found the specimen originally and it seemed possible, though not very probable, that the specimen may have had an entirely different provenance. Mr. Crawford's letter solves all my difficulties, and it is very satisfactory to have the little mystery cleared up. The specimen which I examined was undoubtedly *E. gracilis*, and its provenance the water supply of the Metropolitan Water Board.

Points from Foregoing Letters

A DESCRIPTION of the spectra of 'northern lights', both red and the 'sun-lit', usually feeble, grey-violet auroras, simultaneously photographed from several Norwegian stations, is supplied by Prof. Carl Störmer. The height of the red auroras was mainly between 100 km. and 500 km., whilst some of the 'sun-lit' auroras had their summit above 800 km. and in one case reached 1,100 km. above sea-level.

Photographs showing patterns obtained by means of a Fabry-Perot interferometer with radiation scattered by phenol, butyl alcohol and acetone are submitted by Sir C. V. Raman and B. V. Raghavendra Rao. The pattern given by phenol is indistinguishable from that of the incident radiation and indicates, according to the authors, that in such highly viscous liquids the sound waves of high frequency necessary for reflecting the incident light are absent, while in the more fluid acetone the greater intensity of the components shifted by the Doppler effect indicate the existence of organized sound waves, as part of the thermal agitation.

Referring to the history of the thermometer, Dr. Kirstine Meyer quotes from Rømer's "Adversaria" to show that he used, as lower fixed point (7½° on his scale), the melting point of snow or crushed ice, and not a freezing mixture of ice and salt. Dr. Newton Friend agrees that Rømer used melting ice as control for his point at 7½°, but considers that his original scale must have been based upon the temperature given by ice and salt or ice and sal ammoniac, which closely agrees with the zero point on Rømer's scale.

Curves showing the changes in the absorption spectrum of a solution of visual purple after exposure to light, and afterwards on standing, are submitted by Dr. G. Wald. These, he considers, show the common belief, that the orange colour brought about exposure to light is due to a mixture of unbleached visual purple and final yellow product, to be mistaken. The orange colour, he states, is itself a new pigment which fades to yellow retinene in complete darkness.

Dr. N. Hamilton Fairley reports in the plasma of severe cases of blackwater fever a new pigment which hitherto has been mistaken for methæmoglobin. The pigment has never been found within the corpuscle, fails to appear in the urine, and by its spectrogram and a number of chemical reactions is readily differentiated from methæmoglobin. It may be readily produced *in vitro* by incubating a solution of oxyhæmoglobin and plasma for 48 hours at 37°–40° C. Pseudo-methæmoglobin is suggested as an appropriate name for the new pigment.

The effect of testosterone propionate in inducing mating behaviour in young rats which had been castrated when young (before the beginning of sexual behaviour) are described by Dr. H. A. Shapiro.

When living cells are injured or killed by ultraviolet light, they produce substances which stimulate respiration, etc., according to experiments by J. C. Fardon, R. J. Norris, Prof. J. R. Loofbourow and Sister M. V. Ruddy. From irradiated yeast, also from liver, kidney and embryo tissue active substances were obtained which could pass through a filter or dialysing membrane. Different orders of potency with regard to stimulation of respiration, proliferation and fermentation were observed, which suggests the existence of at least three substances responsible for the effects.

Experiments described by L. Shubnikov and I. Nadhutin show that a single spherical crystal of tin in the 'intermediate' supraconducting state (when the magnetic permeability is no longer equal to zero) possesses anisotropic supraconductivity. When the direction of the current is parallel to the external field, the sphere remains supraconductive even when the magnetic permeability is near unity; in the direction perpendicular to the field, supraconductivity vanishes at field strength 2/3 H_k.

Bands in the red, yellow-green, green and blue have been obtained by Dr. R. W. B. Pearse and A. G. Gaydon in the spectrum of an electric discharge between manganese poles in a hydrogen flame. These bands are attributed to manganese hydride, MnH. The nature of the electronic transitions are discussed in relation to the levels of the manganese atom.

The analysis of a band spectrum of mercurous chloride (HgCl) vapour, in Dr. K. Wieland's opinion, supports the view that the ground state of this molecule is built up from unexcited atoms. This does not agree with results from the spectrum of CdF obtained by Samuel and his co-workers, who suggest that the ground state of CdF, like that of all diatomic oxides and halides of the second group, is formed from a metal atom in an excited term only.

The molecular constants of gold deuteride have been calculated by S. Imanishi from the arc spectrum obtained between gold electrodes in heavy hydrogen gas.

W. E. Benham gives a simple electronic analysis yielding the electron convection current for any periodic total current waveform. The solution is in terms of the instantaneous electron transit time, and permits calculation of the *n*th harmonic in a valve if the transit time is known to the ($n - 1$)th order only.

Religious Beliefs of Serbian Gypsies

Dr. Alexander Petrovič, in continuation of his studies of the Serbian gypsies (*J. Gypsy Lore Soc.*, Ser. 3, 16, 1–2) deals with religion and superstitions. The Serbian gypsies, who speak the Romani language, can be divided into two groups of a higher and lower culture. The first are permanent city-dwellers, while the latter have no permanent place of habitation. The former have adopted the religions and customs of other people, but with a difference. The beliefs of the second class appear to preserve some of the elements of the ancient gypsy religion. *Del* is God, the sky or heaven, or the clouds. *Del* is the unlimited space above the earth, and sends rain, snow, hail. Once *Del* was close to the earth. This was when life was good to live, and everything came easily. But *Del* was offended and moved away. *Dji* is the stomach or abdomen, and also the soul. If asked where the soul is situated, a gypsy will point to his navel; but if a physical condition of the stomach has to be described, they use *por.* *Dji* is also the heart. In Bela Crkva gypsy musicians use one word *odji* for both heart and soul. *Dji* is the centre of everything, the most precious part of anything, and also the breath of one's being. When a man dies "the soul (*dji*) escapes hence by the mouth". Coano "vampire", "ghost", is the word used also for the soul that goes out of the mouth when a man dies. As soon as a body was placed in the grave, the mourners used to throw earth on it and run away, and no one looked back, because the ghost would think he was being called and follow. The spirit of evil is *Beng*, who appears incarnate immediately his name is mentioned. The gypsies do not know if Good exists in the world, but they are sure that Evil does. *Kar*, "man", "male", and the male organ of generation brings luck. It is the creative and active principle. *Kar* is used in oaths instead of "God". In looking at their religion as a whole it must be emphasized that they are realists, and believe in what can be seen, for example, the identification of God and sky. *Del* gives but does not create. The creative principle is *kar*.

Kutchin Potlatch

Dr. Cornelius Osgood has attempted, as part of a study which will cover eventually the northern Athapascan area as a whole, a reconstruction of the culture, as it was about one hundred years ago, of the Kutchin, or rather of the several tribes known by that name, who inhabit the country from the region around the great bend of the Yukon River, eastwards into the valley of the Mackenzie, north to the littoral of the Arctic Ocean held by the Eskimo, and south to roughly lat. 65° north (*Yale Publications in Ethnology*, No. 14). His observations include an account of the potlatch, of which the performance was most fully celebrated among the Crow River Kutchin. It was given in honour of a person deceased, but at no other time or occasion. The donor, a relative, accumulated food and property for the purpose during the period of mourning. A period of one to two years might elapse, and the size of the potlatch would depend upon the wealth and influence of the persons involved, as well as on whether it was a time of plenty or scarcity. The primary purpose seems to have been the enhancement of family or personal prestige, as well as, in the background, the idea of reciprocity. The potlatch was generally held in a special ceremonial ground or enclosure. The fence served the purpose of apportioning the gifts, skins and so on, which were set out there on display. The duration of the potlatch correlated directly with the elaborateness of the display and the time required to consume all the food prepared. In a small potlatch, only the local population participated. In the larger, other tribes were invited to attend. Important or distant guests were formally escorted to a suitable reception, watch for their approach being kept night and day for some time. On arrival, the leader of each group made a suitable speech, and a welcoming reply was made. Dancing was a common activity during the ceremony. Speeches were made at intervals, and games and tricks played. The final act was the distribution of gifts, performed by a friend of the giver who was paid for his service.

Impaction of Man's Third Molar Teeth

Mr. Bowdler Henry and Dr. G. M. Morant give an account of a preliminary examination they have made of skiagrams showing man's wisdom teeth in the process of eruption (*Biometrika*, 378, Dec. 1936). As is well known, eruption of a tooth involves an elaborate series of growth movements not only in the tissues which surround a cutting tooth, but also in parts of the bony tissues at a distance. The growth movements which bring up the third molars—man's wisdom teeth—are particularly complicated, and are very apt to be delayed or arrested, particularly in western Europeans. The teeth most liable to arrest are the lower molars. The impaction of these may give rise to disorders so serious as to threaten the life of a sufferer. It would be a great advantage if a dental surgeon could tell, from the examination of dental skiagrams of young people, whether or not their wisdom teeth were likely to become impacted. Mr. Bowdler Henry has proposed certain methods, based on the examination of 622 skiagrams. His results have been examined statistically by Dr. G. M. Morant. They have determined to extend the investigation, but meantime certain hints are given which are likely to have a practical value for dental surgeons.

Sponges of the Panama Canal

Dr. M. W. de Laubenfels has recently compared collections of shallow-water, and mainly intertidal sponges, made by him at either end of the Panama Canal, during the summer of 1933 (*Proc. U.S. Nat. Mus.*, 83, No. 2993; 1936). Among a total of 31 species collected, 10 are restricted to the Pacific side, 15 to the Atlantic side, 6 being recorded from both sides. New species are described in the respective proportions of 4 to 16 on the Pacific side, and 6 to 21 on the Atlantic side; not as 5 and 7 respectively, as stated, apparently in error. With the exception of four strictly keratose species, including two Hircinimæ, from the Atlantic side, and one, *Aplysilla*, from the Pacific, all are siliceous species, the Calcarea not being represented.

The Teak Borer of Burma

THROUGHOUT the main teak-bearing areas of Burma, the timber suffers from the beehole or gallery caused by the larva of a large moth, *Xyleutes ceramica*. This insect is a member of the primitive family Cossidæ to which the familiar goat moth (*Cossus cossus*) of Britain and other European countries belongs. A survey of the injuries caused by the beehole borer has recently been made by Mr. D. J. Atkinson, forest entomologist for Burma. His account forms No. 1 of vol. 2 of *Indian Forest Records* (N.S.), Entomology (1936) wherein data are given for the mean incidence of the borer as affecting 1,001 trees taken from 56 localities. Average rainfall is a sound index of the probable severity of the damage: below the isohyet of 55 in., conditions become less favourable to the insect. It was also found that much of the naturally grown teak timber in Burma is more heavily infested than a great deal of the plantation timber. The faster growth of the latter operates to advantage, and serves also to accentuate the natural tendency for an increase in beehole borer damage towards the centre of the tree, and the faster the growth of the tree the greater the volume of comparatively borer-free timber which will be produced. Where conditions are suitable, heavy and repeated thinnings to encourage the volume increment, to outstrip the borer increment, are advised.

Storage of Pollen

THE possibility of storing pollen from one year to another has distinct advantages in horticultural practice. Hitherto, although methods have been devised for transplanting pollen over considerable distances, the maximum viability has not extended beyond the current season. B. R. Nebel and M. L. Ruttle (*J. Pom. and Hort. Sci.*, 14 (4), 347; 1937) have succeeded in keeping pollen of apple and sour cherry in store for more than two years, and their data indicate that similar longevity may be attained by pollen from pear, plum, sweet cherry and grape. The latter species have been stored for more than a year, but the experiments are as yet incomplete. The period of life of apple and sour cherry pollen stored at 2°–8° C. increases with decreasing humidity from 100 per cent to 50 per cent, the latter being the optimum. Apple pollen which had apparently lost its viability after being stored in the laboratory for five weeks was revived by storing at 2°–8° C. and 80 per cent humidity. Pollen from several common varieties of the species mentioned was used, and the success of the experiments should enable plant breeders to make crosses between varieties which flower in different seasons or are separated geographically.

Effect of Oxidizing Agents on Crop Production

PROF. V. SUBRAHMANYAN, C. R. Harihara Iyer and R. Rajagopalan, of the Indian Institute of Science, Bangalore, in a communication to the Editor, have directed attention to the possibilities of increasing crop production through judicious applications of chemical oxidizers, and have outlined the attendant chemical and biological changes. All crops showed increase in yield on both unmanured and manured soils. The oxidizing agents differed in efficiency, potassium permanganate usually being more active than either hydrogen peroxide or ferric oxide. Permanganate gave the best results when applied as a basal dressing, while manganese dioxide was most efficient as a top dressing. The crops also varied in their response to different oxidizers. Ammonia production in the soil was increased, and the oxidation of organic matter facilitated, but the biological changes consequent on the application of oxidizers were not pronounced. With permanganate there was an initial depression in the number of bacteria followed by a rapid rise after the fourth day. Soluble manganese salts applied to soil pass into an insoluble form and oxidation of organic matter occurs with the production of carbon dioxide, particularly on non-sterile soils. There is some evidence that biological activity is stimulated, resulting in greater production of carbon dioxide and increased plant assimilation. Manganese dioxide and permanganate gave the best results, manganous sulphate following next in order, while manganous carbonate was not much superior to untreated control. Pretreatment with lime was found to depress the yield, at any rate in the case of the eight varieties of tomatoes that were tried. In none of the cases was there any evidence of increased intake of manganese. The foregoing and other observations would suggest that although certain inorganic compounds may produce profound physiological effects in culture solutions, through purely ionic action, they act in a different way in the soil, this being particularly true of manganese salts, which are rendered insoluble in the soil.

The Structure of a Cellulose Wall

THE *Valonia* cell wall, of which a model is figured by Drs. R. D. Preston and W. T. Astbury in a recent paper (*Proc. Roy. Soc.*, B, 122, No. 826, March 3, 1937) must have been submitted to far more intensive study than the cell wall of any other individual cell. As a result, a most interesting and complicated structure is revealed. The cellulose chains in one of these layers form a system of meridians in the wall running from the base to the apex of the cell, and the chains of the alternate layers build a system of spirals closing down on the two 'poles' defined by the meridians. The X-ray photographs confirm the fibrillar structure suggested by the microscope, and it is now clear that the *Valonia* wall is built of alternating layers of differently orientated cellulose fibrils which cross each other at an angle of a little less than 90°. The major extinction position shown by the polarizing microscope bisects this angle approximately, though its position varies with the varying proportion of the two types of lamellæ. It is abundantly clear that the direction of the cellulose chains in a cell wall cannot be reliably determined by observations with a polarizing microscope alone. The authors discuss the involved problems presented by the deposition of such a wall by the growing cell. There seems no doubt that the patchwork appearance indicated in surface view on examination by the polarizing microscope is the result of the cracking of the outer layers by the continued volume expansion of the growing cell, but it is difficult to visualize a mechanism which should lead to the successive deposition of layers with cellulose chains crossing at an angle of nearly 90°.

The Aluminizing of Telescope Mirrors

On *Leaflet* No. 96 issued by the Astronomical Society of the Pacific, Dr. J. Strong of the California Institute of Technology, contributes a short article on "What Aluminium has done for the Reflecting Telescope". An account both of the history of the coating of mirror surfaces with aluminium and other metals by an evaporation process, and of the promising astronomical results obtained with reflectors that had been aluminized, has already been given in Nature (134, 522; 1934). The chief advantages of using aluminized mirrors in telescopes are: (1) the high degree of reflectivity and freedom from scattered light maintained over a considerable period of time, as compared with the life of a silvered surface; (2) the high reflectivity in the violet end of the spectrum where a silvered surface absorbs strongly. Thus, aluminium reflects 87 per cent of the incident light below wave-length 4100 A., whereas the reflectivity of a freshly silvered surface rapidly diminishes from 90 per cent at λ4100 to only 4 per cent at λ3150. Consequently, with an aluminized optical train, it is possible to photograph stellar spectra down to the limit of transmission of the earth's atmosphere at about λ3000. This latter property has enabled Wright at the Lick Observatory to discover new emission lines in the spectra of planetary nebulæ, while Duncan has found the existence of an outer envelope to the well-known ring nebula in Lyra. Another illustration of the value of aluminized surfaces is the fact that after the mirrors of the 60-inch and 100-inch reflectors on Mount Wilson had been aluminized, it was found that the resulting gain at the Cassegrain focus (involving reflections at three surfaces) was equivalent to one photographic magnitude, or about the increase in light grasp of the 100-inch as compared with that of the 60-inch. Although in the process of aluminizing smaller mirrors difficulties are sometimes encountered, Dr. Strong thinks that no unusual problem will be presented in aluminizing the 200-inch mirror when it is ready; the 36-inch Crossley reflector at the Lick Observatory and the two great telescopes at Mount Wilson have already been successfully treated.

Electricity in Mining

To the *Journal of the Institution of Electrical Engineers* of February, Prof. W. M. Thornton contributes an interesting review of the progress made in the use of electricity in mining during last year. A recent figure for the number of electric units consumed per ton of coal raised is 25. This includes the heavy pumping demands. In Northumberland and Durham alone, it has been estimated that 125 million tons of water are raised annually. This is enough to form a lake of 25 square miles in area and 6 feet deep. Underground haulage, for which an electrical drive is admirably suited, takes nearly as much power as pumping. But there are still 40,000 ponies employed in Great Britain on underground haulage. This may be compared with 64,000 ten years ago. Considerable improvements in the design of ventilating fans for collieries have recently been made, embodying the most recent theories of air screws. A 300-h.p. fan, in use at Dodworth colliery, has an 89 per cent efficiency—a remarkable performance. The flame safety lamp in its early days showed the presence of high proportions of firedamp by the gauze becoming red hot. In capable and trained hands it proved on the whole a trustworthy guide to the percentage of firedamp in the mine. But it cannot, in unskilled hands, be used to detect the safety limits of 1¼ or even 2½ per cent. Two forms of electric safety lamp have recently been fitted with a means of rapidly detecting 1–4 per cent of firedamp. One of these, the Gray 4-volt acid lamp, is coming into use, and is approved by the Mines Department. An interesting development is the electrostatic precipitation by the Lodge method of the finely divided tar fog in coal or coke-oven gas. Two 15,000 volt d.c. generators are mounted on insulators and connected in series. The negative terminal is connected to a wire grid and the positive to plates. On the application of the field, the fog becomes charged negatively, deposits on the positive plates, and falls. In one such plant about 6·5 million cubic feet are treated daily, and practically every trace of fog is removed. The currents used vary between one twentieth and one half an ampere

Synthesis of Fluorene Compounds

Further contributions to the study of diphenyl and its derivatives have been published by Prof. L. Mascarelli and his co-workers (*Atti Accad. Sci. Torino*, 72, 64 and 109; 1937). Of special interest is the behaviour of 2-4′-dimethyl-2′-aminodiphenyl, the preparation of which is described. When this substance is diazotized and the product boiled with water, an almost theoretical yield of 2-methylfluorene is obtained. This reaction provides a second example of the direct synthesis of a fluorene ring compound from a diphenyl derivative, which was discovered by Mascarelli in 1932. The trisubstituted diphenyl compound 2-6′-dimethyl-2′-aminodiphenyl, when subjected to a similar treatment, gives only a small yield of 4-methylfluorene. With a tetrasubstituted diphenyl derivative, no fluorene ring synthesis occurs. The subject is further discussed in a paper by Prof. Mascarelli (*Gazzetta Chimica Italiana*, 66, 843; 1936).

Colour Variation in the Equatorial Belts of Jupiter

Mr. A. Stanley Williams, a very assiduous observer of the planet Jupiter, contributes an interesting paper on this subject to *Mon. Not. Roy. Astro. Soc.*, 97, 2 (Dec. 1936) which deals with his observations from 1930 to the end of last year. His first paper on the subject, published in 1899, showed that the observations up to that date indicated a period of 12·08 years in the variation, and his second paper in 1930 gave a period of 12·5 years. The results of the last six years' work show that the period must be shortened to 11·86 years, the period of the revolution of the planet around the sun. The adopted elements of variation are: Standard epoch = 1838·52 + 11·86 E years. At the time of a standard epoch the North Equatorial Belt is at or near a minimum of redness, while the South Equatorial Belt is at or near a maximum. At intermediate epochs the colours of the belts are reversed from those just mentioned. As the computed date of the next standard epoch is 1945·2, when the North Equatorial Belt will be at or near a minimum of redness, and the South Equatorial Belt at or near a maximum, observations during 1945 and a year or two before and after are highly desirable.

The New Forest*

ORIGINALLY an old Crown forest, and nowadays the most extensive of these remnants of the old Royal forests, the New Forest, in Hampshire, comprises some 90,000 acres and is under the management of the Forestry Commissioners. The Forest comes under the designation of a true forest, though large areas consist of open heath-land subject to rights of grazing and so forth ; these limit planting and other forestry operations which would constitute the area a commercial proposition. Perhaps no other area of the type has received so much attention from Parliament, and numerous Acts have been passed for the administration of the law relating to it. The Acts of 1877 and 1879 may be said practically to have settled the Government policy *vis-à-vis* the forest, which is now regarded as a national playground ; the coming of the motor-car having enormously extended the area from which visitors now resort to the Forest. These factors are rendering its management, even from the sole point of view of maintaining its beauty for future generations, a delicate and difficult task.

Apart from the Forestry Commission, several bodies such as the New Forest Association, the Court of Verderers, the Scapa Society, the Council for the Preservation of Rural England and the New Forestry Advisory Committee constitute what may perhaps be best expressed as vigilant committees over the maintenance of the Forest in its pristine beauty.

Some of the difficulties confronting the management are portrayed in the annual report for 1936 of the New Forest Association. The objects of the Association are given as follows : "The preservation of the general picturesque aspect of the Forest and the old woods and the protection of the rights and privileges of the Commoners and of the Public in the enjoyment of the Forest." From the professional forester's point of view, some of these objects are conflicting, so far as the public are concerned. To give one instance, the preservation of the picturesqueness of the old woods, for example, the Mark Ash inclosure of old beech, famous during the past half century amongst artists and other lovers of scenic beauty. How is this old wood to be perpetuated ? The wooded parts of the forest, the beautiful inclosures of old broad-leaved trees, present analogous cases.

The New Forest Association has its own problems. One of the first mentioned would be scarcely understood by European Continental nations, accustomed to regard forests as economic commercial propositions. The matter in question is the spread of seedling fir trees coming up from blown seed. The spread of these young trees is said to be continuing at an alarming rate ; with the obvious result that their growth in height will interfere with the beautiful views over the open forest, which it is one of the objects of the Association to maintain ; whilst it is said that the presence of the trees diminishes the grazing area. The attention of the Forestry Commission has been directed to this, one of Nature's own acts. It is a curious anomaly to find man fighting against Nature in her effort to provide him with produce free of cost ; whilst elsewhere in the country the Commission is spending pounds per acre planting the very same type of tree. The cost of continually removing these young trees would, it is said, be considerable.

If one of the objects is to maintain the grazing, should not such work be undertaken by the right holders who own the grazing ? The Association suggests a special grant being made by Government ; but it is difficult to see how the expenditure of the tax-payers' money on such an object could be justified.

The Association has saved the Forest from pylons, but with the praiseworthy aim of making electricity more commonly available, poles and overhead cables are on the increase. The report alludes to litter dumping and the refuse left by visitors, and rightly considers that education and persuasion, of the old as well as the young, are the chief means by which litter may be gradually decreased.

The New Forest ponies present a problem. Within the Forest boundaries they are on their own ground. But of late years they have taken to straying outside the boundaries. In the days before the motor-cars on the roads had reached their present numbers, there were gates on the roads leading into the Forest. The value of these latter, nowadays always left open, has disappeared. The 'grid', so commonly seen at the entrance to drives of private houses, was suggested, but the County Surveyor expressed his opinion that his Council would not be prepared to make the grids. So this problem remains unsettled. Oil prospecting in the Forest has raised a scare, but nothing definite has yet transpired, save the fact that the Association would raise the strongest objection to the desecration of the Forest by such operations.

All the inclosures in the Forest have gates, a field gate and a small hunting gate alongside. These are all left unlocked. The Association quite correctly urges on the public always to close the gates on passing through ; or the courtesy of the Forestry Commission in leaving the gates open may be withdrawn.

Probably the most important part of the report lies in the remarks on the condition of the Forest, and these remarks will receive support from many who, though non-resident, are well acquainted with the Forest. As the report puts it : "The Council have for many years past viewed, with great concern and alarm, the great deterioration in the condition of the open and enclosed spaces of the Forest to which the public have access. They interpret the New Forest Act 1877 as laying down that the amenity of the Forest is the object of management, and that any consideration of profit should take a second place." It may be mentioned that in many parts of the Continent of Europe it is regarded as quite feasible to secure both objects by a correct management without a loss of amenity. But the present condition of parts of the Forest is reducing amenity and its use by the public and is equally uneconomic. The most glaring item in this want of management is the neglect of draining over areas of varying size throughout the region—a neglect which cannot be laid to the door of the Forestry Commission ; for it is the aftermath of the want of efficient management in these matters of a century or more.

Disease Resistance in Plants

VOL. 3, No. 6, of the *Proceedings of the Indian Academy of Sciences* is devoted entirely to the papers submitted for the symposium at Coimbatore in October 1935 on "Disease Resistance in Plants". Interest in the contributions lies in methods of stimulating disease resistance. These are adopted as a result of investigations along the lines of inheritance of resistance, structural modification associated with resistance and physiological conditions associated with the plants' response to the disease. Thus in the case of sugar-cane, frequently attacked by mosaic, N. L. Dutt, Syed Abbas Hussainy and M. K. Krishnaswami; C. S. Krishnaswami, and others, have found it possible to breed resistant plants and that those with *Saccharum spontaneum* parentage are more resistant than others.

Other workers, investigating the wilt disease of cotton (due to attacks of *Fusarium* species), have found that environmental conditions are important factors in relation to susceptibility, and in particular soil management can control the disease. A striking example of this is furnished by the work of B. B. Mundkur, who shows conclusively that in the case of *Fusarium vasinfectum* the American variety could not attack American cottons on Indian soils, and will not attack Indian cottons in any circumstances, whilst Indian cottons are less susceptible to the Indian variety of *Fusarium* on American soils. It is interesting to note that American soil in affected districts is light sandy and acidic, whilst affected Indian soils are heavy clayey and alkaline. Soil conditions (mainly physical) have also been found by J. Madhusudan Rao and Yeshwant D. Wad to be responsible for development of leaf roll and red leaf in American cottons.

With reference to anatomical developments in relation to disease, B. P. Pal shows that in certain varieties of gram (*Cicer Arietinum* L.) which are affected by the cutworm, those which are relatively immune have large stem diameters and extensive development of woody tissues, while severely attacked varieties show a smaller stem diameter and poorly developed secondary wood.

In most cases work has been carried out under field conditions and in connexion with various growers, so that some very interesting statistics are possible in view of the quantity of material available.

Progress in Building Research

A PERUSAL of the report of the Building Research Board for 1935 recently issued by the Department of Scientific and Industrial Research (H.M. Stationery Office. 3*s*. 6*d*.) shows how elementary is our scientific knowledge of building technique. In his introductory survey of the recent work of the Board, Dr. R. E. Stradling, the director of research, suggests that a wrong emphasis has been given by concentrating on the engineering side, strength and stability of structure being studied to the neglect of other equally vital considerations associated with the "Efficiency of Buildings from the Standpoint of the User".

Recent developments have given special prominence to three of these problems, especially in connexion with slum clearance schemes. The increase of noises of all kinds and the influence of mechanical continuity, as adopted in modern construction, in causing a sound made at one point to be extended over a large area, have made the sound insulation problem serious and pressing. The results of earlier work on walls, partitions and floors, treated individually, have focused attention on the interaction of the several elements of a building, and this is now being investigated with the full realization of treating the building as a whole. Trials are in progress on a frame building, on the principle that the construction should be such as to confine the noise to the room in which it is made; and this is arranged as a box, built into, but acoustically insulated from, a structural framework. It is appreciated that unforeseen troubles may arise in the full-scale developments, but "these must be overcome for the need is urgent".

From the same source comes the difficult problem of bug infestation, in which the survey work carried out has shown that virtually every urban authority is more or less troubled with this problem. Dr. Stradling urges that the building industry should endeavour to contribute to its solution by preventing the formation of cracks and by devising a form of construction which will, when the need arises, admit of disinfestation by the poisonous gases at present used, without danger to the occupants of surrounding houses.

It is claimed that considerable advance has been made towards placing the investigation of fire resistance on a scientific basis by the provision of a fire-testing station at Elstree, where full-size building elements are tested and graded in accordance with the new specification. Arrangements have been made for a programme of research covering not only the investigation of different forms of construction but also of tests of proprietary systems with the view of issuing appropriate certificates.

In the demolition of Waterloo Bridge, opportunity has been taken to investigate the condition of granite after exposure for 120 years. The outer half-inch was found to be seriously affected, but no reason appeared to suggest that decay would have become apparent in the near future had the structure been undisturbed. Laboratory examination of Portland stone from St. Paul's Cathedral also showed that, except for surface portions, the material was sound and, with regard to the use of old stones, the report states that, in the case of the more durable kinds, provided an appropriate thickness is removed, these should prove as good as new.

Materials for cleaning buildings have been under review, and a number of proprietary preparations investigated. It is pointed out that it is inadvisable to use chemical methods, and that alkalis are equally as dangerous as acids. Examples of the deleterious effects of cleaning in stone walls, door jambs, etc., are quoted.

Work on the effect of firing conditions on the properties of bricks has shown that specimens fired to below 900° C. offered only a moderate resistance to disruption by the crystallization of soluble salts whereas, with one exception, all the clays tested proved satisfactory in this respect when fired to 1,000° C. The unsightly efflorescence on brickwork is caused by soluble magnesium compounds, particularly the sulphate, contained in the bricks, and the only certain method of its elimination is firing to a temperature of above 1,050° C.

The report also contains particulars of tests made on the heating, cooling and lighting of buildings. The notable difference in the temperatures inside a wooden shed, before and after whitening it, is shown in the results of one inquiry, while the diminution of the lighting of a room due to a balcony or neighbouring building is the subject of another. Particulars of the work carried out in conjunction with other bodies and on behalf of manufacturers, indicate the value of the scientific services rendered by the Building Research Board both to the industry and to the interests of the public.

The Machinery of the *Queen Mary*

THE ninth Thomas Lowe Gray lecture was delivered before the Institution of Mechanical Engineers on January 8 by Mr. John Austin, superintendent engineer, Cunard White Star, Ltd., and took the form of a description of the main and auxiliary machinery of the *Queen Mary*.

Mr. Austin pointed out that since the advent of steam propulsion, the trend of development in the design of Atlantic liners has been towards larger and faster ships, and the several commercial and technical considerations which determined the size and speed of the new vessel were explained. Before a decision was taken as to the type of machinery to be installed, a committee of eminent engineers was invited to advise the directors, and they unanimously recommended high-pressure water-tube boilers with superheaters and air-preheaters and, for propulsion, single reduction geared turbines as being most suitable by reason of their reliability, simplicity, lightness, efficiency and freedom from noise and vibration. To meet emergencies and to maintain the fortnightly schedule, a large reserve of steaming capacity was provided and, in relation to the normal power required, it is of particular interest to the engineer to note how much design of hull and propellers has improved. From the table of figures given, the *Lucania* of 1893 had a gross tonnage of 12,952, horse-power 27,650 and speed 21·9 knots. The *Queen Mary* has 6·2 times the tonnage, but only 5·7 times the horse-power, although her speed is 1·2 times that of the *Lucania*.

The arrangements to ensure economy and to obviate delays and damage are as complete as human ingenuity can make them. Salt-water detectors are fitted at every point where salt-water might leak into the feed-water system, and give audible and visible warning when the concentration reaches 2 grains per gallon. Automatic feed-water regulators ensure a steady water-level in the boilers. The adoption of the closed stokehold system of forced draught has obviated the need for massive air ducts, and maintains better ventilation and working conditions. Each boiler has a complete system of steam soot blowers, and the arrangement by which boilers and propelling machinery have been divided into two quite independent systems—only practicable in a ship of such large size and power—ensures that, in the event of breakdown in one section, the whole propelling machinery is not put out of action.

The steering and manœuvring of a ship of this size necessitates a rudder of large area and, this being of streamline unbalanced type, powerful operating gear had to be installed. The torque is supplied by four hydraulic rams acting on tillers projecting from the rudder-stock. For safety, the essential parts were duplicated and the pumps are driven by three electric motors each of 250 h.p., the switchboard of which is operated by servo gear of the electro-hydraulic type controlled by hydraulic telemotors working in conjunction with the steering wheel on the bridge.

Crystalline Structure of Cellulose

PROF. K. H. MEYER reviews in the February issue of the *Berichte der deutschen chemischen Gesellschaft* the evidence upon which the structure of the crystalline part of cellulose has been based, and suggests that certain alterations are needed in the accepted model which was constructed from X-ray intensity measurements carried out by Andress in 1929.

Fortunately, the existing calculations upon the dimensions of the micelles or crystallites remain for the most part undisturbed, since the latter are independent units and the cellubiose type of linkage is not challenged. But the grouping of the micelles needs reconsideration. Hitherto it has been assumed that they all run in the same direction.

There seems to be no valid proof that this is the case, and the fact that *precipitated* hydratcellulose possesses the same crystal lattice as that of the mercerized fibre makes it highly improbable that all the chains are similarly orientated. There is, in fact, no reason why an equal number of chains should not be formed in opposite directions by precipitation.

Moreover, the minor alterations in dimensions, which have resulted from new X-ray intensity measurements, show that the suggested new model, in which the crystallites are arranged to run alternately in opposite directions, is more in accordance with measurements than the older one. In particular, there is no longer any need for deviations from the tetrahedral angle in the side-chains, and the recalculated distance of 2·6 A. between hydroxyl groups of neighbouring chains, agrees well with the recent measurements by Bernal on hydroxyl distances.

It is known that a small amount of oxidation occurs in native cellulose and it is suggested that the resulting acid groups may esterify with neighbouring micelles. This may account for the resistance to methylation observed by Karrer to the extent of about 8 per cent of the hydroxyl groups. No information could be derived about the ends of the chains, but it is pointed out that in the new model the terminal aldehyde groups might lose their identity by forming glucosidic links with the terminal alcoholic groups of the other micelles to form giant rings.

Birmingham Conference on Industrial Physics

THE rapid development of industrial applications of physics to industry in recent years has brought with it the desire for opportunities for the interchange of ideas and for the discussion of the many and varied topics which have consequently arisen. The more enterprising industrialist also desires opportunities of learning of these latest developments in order to keep himself abreast of his competitors, especially those abroad. The Institute of Physics is endeavouring to meet this demand by founding branches both at home and overseas, and by holding periodic conferences on industrial physics. The first Industrial Physics Conference to be held took place in Manchester in 1935 (see NATURE, April 6, 1935, p. 555) and the second was held in Birmingham on March 8–20, the subject being "Optical Devices in Research and Industry".

The sessions were held in the University of Birmingham. The Conference was formerly opened by Mr. Walter Barrow, pro-chancellor of the University, and was presided over by the president of the Institute, Prof. A. Fowler. Following the established practice of the Institute, the lectures were all informal in character and were followed by discussions. Neither the lectures nor the subsequent discussions will be published, except the presidential address, which will appear in an early number of the *Journal of Scientific Instruments*; the title of this address was "Spectroscopy in Industry". The other lectures were: "Colorimetry, Spectrophotometry and the Inspection of Manufactured Products for 'Appearance' ", by Mr. R. Donaldson, of the National Physical Laboratory; "The Application of Electron Diffraction to Industrial Problems" by Prof. G. I. Finch, of the Imperial College of Science and Technology; "Industrial Uses of Photocells" by Mr. A. L. Whiteley, of the British Thomson-Houston Co., Ltd.; "Optical Gauges for Metrology and Engineering" by Mr. F. H. Rolt, of the National Physical Laboratory; "Polarimeters, Saccharimeters and Refractometers in Sugar, Jam-boiling and other Industries", by Mr. L. Eynon, of Messrs. Eynon and Lane, official analysts to the Sugar Association of London. The attendance at each of the lectures was excellent, averaging 325. Both the lecturers and those who took part in the subsequent lively discussions dealt with recent industrial applications of the various optical and allied devices and the associated problems, rather than with the technical details and underlying principles of the devices themselves.

On March 20 parties of Conference members were able to see the direct application of physics to industry in the Longbridge Works of the Austin Motor Co., Ltd., the engineering works of the General Electric Co., Ltd., and the Research and Development Department of the Mond Nickel Co., Ltd., as well as the associated works of Messrs. Henry Wiggin and Co., Ltd.

Twenty-three firms and research organizations were represented at an Exhibition of apparatus, instruments and books cognate to the subject of the Conference, which was held in the physics laboratories of the University. The Government's recognition of the importance of physics to industry was demonstrated by several exhibits contributed by the National Physical Laboratory and the Post Office Engineering Research Station. A special section of the exhibition was devoted to optical experiments of general interest, including many ingenious applications of photocells. The object of the whole Exhibition was to demonstrate the existence of apparatus and instruments designed on well-known physical principles for use in the workshop and factory. It was agreed, even by those familiar with the subject, that the wide range covered by the devices shown was considerably more extensive than is generally appreciated. Many instances were recorded in which responsible executives were enabled by this Conference and Exhibition to learn of the existence of devices which should prove of the utmost value in their factories. A limited number of copies of the catalogue of the Exhibition is still available from the Institute of Physics, London, S.W.7 (9*d.* post paid). The educational value of the Exhibition was appreciated by the local schools, and it was visited by parties of senior scholars from them. It is estimated that about 2,500 people visited the Exhibition during the three days that it was open.

Prof. J. A. Crowther, honorary secretary of the Institute, broadcast a talk about the Conference and Exhibition on the eve of its opening, and it also received extensive attention from both the lay and technical press. There was thus further confirmation of the fact that there exists a great demand for information about recent scientific discoveries and particularly their application to industrial and domestic problems.

No report of the Conference would be complete without recording the valuable contacts which resulted from bringing together physicists and industrialists, and the great help rendered by the authorities and members of the staff of the University of Birmingham.

HERBERT R. LANG.

Science News a Century Ago

Egyptian Mummies

The *Gentleman's Magazine* of April 1837 relates that "on March 6 at the close of a series of six very interesting and instructive lectures on Egyptian antiquities delivered at Exeter Hall by Mr. Pettigrew that gentleman unwrapped a mummy presented for the occasion by Mr. Jones of the Admiralty. The inscription on the outer case differed from that on the inner. Both stated the party to have been a female, but the names and genealogies were different, and the latter stated the mother of the deceased to be living when her daughter died. It might be that the wrappings would settle this point; which, however, they did not—for no name was found on them, as often occurs. The mummy was Greco-Egyptian, and embalmed after the ancient manner, the bowels being extracted by an incision on the left flank, and the brains probably through the nostrils, as the nose was much broken. The legs were separately bandaged, and the ankles bound by strips of painted linen, about half an inch in breadth. The figures were not hieroglyphic, but simply ornamental. Bands of the same kind surrounded the arms, which were crossed upon the breast; and a similar circle went round the neck, with a thin golden scarabaeus in front. On each knee was also a thin piece of gold, resembling the lotus-flower; over each eye the providential eye of Osiris of the same material, and another golden ornament upon the top of the ridge of the nose. The upper wrappers were not voluminous, and of coarse nankeen-coloured linen. Then came a complete envelope of asphaltus, and below that the usual disposition and extent of linen robes. On the soles of the feet were slight sandals, transversely striped, black, white, and red, exactly like those painted at the bottom of the inner cases. The finger- and toe-nails were gilt, and there were rings on the fingers."

Henslow's "Descriptive and Physiological Botany"

The first article in the *Athenæum* of April 8, 1837, contained a notice of Prof. Henslow's "The Principles of Descriptive and Physiological Botany". John Stevens Henslow (1796–1861) was professor of mineralogy at Cambridge in 1822–27 and professor of botany in 1827–61. It was he who recommended Darwin as naturalist to H.M.S. *Beagle*. "If any person," said the *Athenæum*, "doubts the truth of the opinion now prevalent, that Botany has of late years undergone a great revolution . . . he has only to compare the introductory work of Professor Henslow with that of Smith, which although now almost forgotten, was, only a few years since, a standard book upon the subject in this country. . . . As a genuine view of the state of opinions upon physiological and structural botany up to the year 1836, we regard the work of Professor Henslow as a valuable addition to our introductory books. It embraces all that is most worthy of the student, briefly expressed in a clear methodical style, and, in general, with a just distinction between those modern speculations which are founded upon exact observations, and those which are mere creations of an inventive imagination."

Prony's Absorption Brake

Under the heading "Dynamometric Check", the *Mechanics' Magazine* of April 8 said: "A Committee of the French Institute, composed of Messrs. Arago, Dulong and Poncelet, has gone through a series of experiments on the 'dynometric (or power-measuring) check', an instrument invented by Prony, and lately improved by M. de Saint Leger, mining engineer at Rouen, for the purpose of measuring with accuracy the power of steam-engines and the quantity of fuel they consume. A large party of members of the Institute and Chamber of Deputies, of professors, engineers, etc., were present at the investigation. The object of the experiments was to ascertain the practical exactness of the apparatus, and for this purpose a steam engine of twelve horse-power of M. Pauweis's manufacture was made use of. The result appeared to be perfectly satisfactory and the scientific world now waits, with some interest, the report of the Committee of the Institute."

Baron de Prony (1755–1839) the inventor of the friction dynamometer, was distinguished both as a mathematician and engineer. He was trained under Perronet at the Ecole des Ponts et Chaussées and himself in 1799 became the director of the school. During the Revolution he directed the preparation of an enormous series of logarithmic tables computed to fourteen, nineteen and twenty-five places of decimals, and under Napoleon superintended the operations in connexion with the regulations of the waters of the River Po, and the draining of the Pontine Marshes.

Societies and Academies

Paris

Academy of Sciences, February 22 (*C.R.*, 204, 533–624).

Henri Lagatu and Louis Maume: The possibility of measuring separately, at any period of growth, the feeding effect and improving effect of an application of manure. The method is based on the analysis of a leaf removed from the plant at regular intervals.

Edouard Chatton and Mme. Simone Villeneuve: The division of the mouth and the formation of the peristome in *Cyclochæta astropectinis*. Their immediate genetic continuity.

René Garnier: Two classical theorems of conformal geometry.

D. Mangeron: Certain problems at the polygonal boundary not totally characteristic for a class of partial differential equations of higher order.

M. Luntz: Alternating thermoconvective vortices in a thin layer.

Douchan Avsec: Thermoconvective vortices in superposed layers.

Albert Toussaint and Simon Strijevsky: The envelope curves of the yield for the best propelling screws.

Svetopolk Pivko: The flow of air in the plane of rotation of a supporting helix.

René Retel: Supplying fuel to a motor with combustion at constant pressure.

Assène Datzeff: The passage of corpuscles through potential barriers.

Bernard Kwal: The classical dynamics of the electron. Theory of prime functions and the true moment of the electron.

Pierre Vernotte: The simultaneous determination of the specific heat and the thermal conductivity of insulators. Method of the signal.

Jean Terrien: Stimulation of the CuCl bands by fluorescence in the vapour of cuprous chloride.

FRED VLÈS and ERWIN HEINTZ : The interpretation of the infra-red spectrum of the proteins. The qualitative and quantitative recognition of the constituent amino acids in the spectra of the proteins is in accord with Fischer's theory of the peptide structure of the proteins : it also supports to some extent the diketopiperazic theory of Abderhalden. It appears to be opposed to the polycyclic theories, which assume a structure where the amino acids are not preformed in the protein molecule.

PAUL SOLEILLET : The passage of the Zeeman phenomenon to the Paschen-Back phenomenon of hyperfine structure in the polarization of resonance radiations.

PIERRE AUGER and MME. GRIVET MEYER : The secondary effects of cosmic rays in free air and in the subsoil.

NARCUS BRUTZCUS : Contributions to the thermochemistry of the hydrocarbons.

ALBERT MICHEL-LÉVY and HENRI MURAOUR : A series of photographs of phenomena accompanying the detonation of an explosive taken at intervals of 0·00001 sec. From earlier experiments, the authors had drawn the conclusion that the intense luminous phenomena caused by the detonation of explosives are caused by the action of the shock wave on the surrounding atmosphere and not to the explosion gases. This view is confirmed by the photographs now described and illustrated.

RENÉ PARIS and PAUL MONDAIN-MONVAL : The influence of small quantities of metallic oxides on the crystallization of zinc borate.

PIERRE DONZELOT and JEAN BARRIOL : The oscillations of the carbon chain of the benzene molecule.

MAURICE BONZEL : The disturbances brought about by cold hardening on the dilatometric diagram of metals.

ADRIEN PERRET and ALBERT BANDERET : The relations between cyanide, cyanamide and nitride in some elements of the rare earth group.

MAX GELOSO and MLLE. EVELINE GIORDANO-ORSINI : The precipitation of copper sulphate by soda.

MARC TIFFENAU and PAUL WEILL : The dehydration of divinylglycol by sulphuric acid Transposition of the hydrobenzoin type with migration of the vinyl radical. Divinylglycol, dehydrated with 50 per cent sulphuric acid, gives mainly vinylcrotonic aldehyde.

PAUL RUMPF : The synthesis of the aminosulphonic acids in the fatty series. Introduction to their electrochemical study.

EDMOND URION and ERNEST BAUM : The catalytic and acid dehydration of divinylglycol. The temperature of the dehydration appears to be the main factor determining the nature of the aldehyde produced by the action of catalysts.

B. MARTIN : Curves of dispersion of the reflective powers of some natural tellurides.

PAUL GAUBERT : The diffusion under the action of heat of the colouring material in crystals of artificially coloured phthalic acid.

LOUIS ROYER : The thermoluminescence of certain crystallophyllian. and eruptive rocks of Algeria.

PIERRE COMTE : The Cambrian and Silurian series of Léon (Spain).

GEORGES CHOUBERT : The geology of the middle Moulouya and the eastern end of the Haut-Atlas.

CHARLES BOIS : Comparison between the values of the focal depth of earthquakes determined by means of Wadati tables and those obtained by means of Brunner curves.

GUSTAVE NICOLAS and MLLE. BERTHE AGGÉRY : The persistance of chlorophyll as a result of bacterial action.

EMILE MICHEL-DURAND : The alteration of the nucleic compounds of plants in the course of their extraction in a trichloracetic medium. Experiments proving that contact with a cold 10 per cent solution of trichloracetic acid produces a notable alteration in the nucleic compounds of the tissues.

RENÉ MORQUER : Morphogenic researches and vital concurrence in the Hypocreaceæ growing on vines.

MAURICE DE CARAMAN and CHRISTIAN CHAMPY : The supposed sterility of the tiger lily (*Lilium tigrinum*) due to its triploid nature.

GUSTAVE MALÉCOT : Some consequences of Mendelian heredity.

LUCIEN BALOZET : The evolutive cycle of *Brachylæmus suis*.

Amsterdam

Royal Academy (*Proc.*, 40, No. 1; 1937).

F. M. JAEGER : Relative and absolute spatial configuration of isomorphous, optically active, complex salts of trivalent cobalt and rhodium. (1) Comparison of the triethylenediamine and tricyclohexanediamine salts.

F. M. JAEGER and L. BIJKERK : Investigations on complex salts of racemic and optically active cyclohexane-1-2-diamines with trivalent cobalt and rhodium. (1) Trans-cyclohexane-1-2-diamine and its fission into optically active antipodes.

J. BÖESEKEN and E. DE ROY VAN ZUYDEWIJN : Some properties of unsaturated sulphanes.

C. U. ARIENS KAPPERS : The spread of primitive humanity and its links with the more differentiated races as revealed by cephalic and cranial index curves.

P. J. HARINGHUIZEN and D. A. WAS : Investigation of thin layers of tin and other metals. (3) The interaction between metals and lubricating oils. Corrosion tests on copper, tin and lead in lubricating oils. The viscosity, surface tension and acidity of the oil are not influenced by reaction with the metal.

D. SCHEPEL : The number of lattice points on and in the neighbourhood of certain curves.

H. FREUDENTHAL : Manifolds and their representations.

N. ARONSZAJN : The lacunæ of a polyhedron and their relations to Betti's groups.

H. G. BUNGENBERG DE JONG and L. W. J. HOLLEMAN : Examples of stable unmixing in binary systems : salt and water. The bichromate of novocain in water shows the phenomenon of stable unmixing at 74° C. (co-existence of two liquid layers).

E. GORTER and L. MAASKANT : (1) The spreading of protamine insulinate. (2) The spreading of urease and Bence-Jones protein.

S. DE BOER and A. BROUWER : The action of medicines on auricular fibrillation. (2) The action of hydroquinidine, quinidinum purissimum, hydroquinine and quininum purissimum on auricular fibrillation.

I. M. KOLTHOFF : Ageing of fresh precipitates in contact with a liquid medium. The irreversible flocculation of colloids.

Sydney

Royal Society of New South Wales, December 2.

H. G. Raggatt: Probable late Silurian age of Serpentine, Condobolin-Trundle District, N.S.W. The dominant rocks of the Condobolin-Trundle district are cleaved argillaceous sediments which fossil evidence indicates are Silurian in age. Devonian rocks overlie the Silurian with marked unconformity. Serpentine and other basic rocks are found intruding the Silurian and cleaved in like degree. Pebbles of serpentine are found in basal Devonian (Middle to Upper) conglomerates. It seems probable, therefore, that the Serpentine was intruded during the late Silurian diastrophism.

R. G. Giovanelli: Energy distributions in the spectra of some gaseous discharge tubes. A spectroscope having been fitted with a wedge-shaped slit, the continuous spectrum was compared with black-body radiation, and found to have a colour temperature of about 5000° A. The energies in the lines were determined in terms of continua, and the total luminosities associated with the lines and continua compared.

H. Finnemore and D. K. Large: Cyanogenetic glucosides in Australian plants (6). *Goodia lotifolia*. An unstable cyanogenetic constituent. *Goodia lotifolia* Salisb. the so-called clover tree, yields in the fresh condition 0·14 per cent of hydrocyanic acid, corresponding to 0·86 per cent on the material dried at 100°. When dried in the air for two days, about 75 per cent of this was lost; the rate then slows down and after about a month only a trace is present. Museum specimens are therefore negative. Steaming for ten minutes removed more than 99 per cent of the acid present. The acetone extract on careful drying and washing with dry ethyl acetate yielded the glucoside of parahydroxybenzaldehyde, recognized after its hydrolysis with emulsin by its constituents and by the hydrolysis of its phenyl hydrazone. Associated with this glucoside was an unstable cyanogenetic material, possibly its cyanhydrin, which continuously gave off hydrocyanic acid, the richest sample contained 2·9 per cent, the whole of this being removed by ten minutes' steaming.

A. R. Penfold and F. R. Morrison: The occurrence of a number of varieties of *Eucalyptus radiata* (*E. numerosa*) as determined by chemical analyses of the essential oils (2). A tree planted from the seed of *Eucalyptus radiata*, Variety *A*, threw two stems from the one root system. The leaves and terminal branchlets were separately examined, when the essential oils were found to differ from one another not only in yield, but also in chemical composition. This provides definite confirmation of the contention that a species described as *Eucalyptus Lindleyana*, Variety *stenophylla* by W. F. Blakely in 1934 does not exist, for the evidence shows that *E. radiata* (*E. numerosa*) and Blakely's variety *stenophylla* have been found growing together on one and the same plant. This observation will exert a considerable influence not only on the economics of the eucalypts, but also upon the botanical classification of this important group of trees.

H. J. Hynes: Species of *Helminthosporium* and *Curvularia* associated with root-rot of wheat and other graminaceous plants. It is pointed out that seven distinct species of *Helminthosporium* have been isolated by various workers from foot-rot-affected wheat in different countries. Of these, three have been isolated and studied by the author from Australian material. The morphological characters of isolates of each of these species are discussed, and it is pointed out that as a result of K. B. Boedijn's new classification in which the small-spored species of *Helminthosporium* are included, the species *Helminthosporium M.* should now be designated as *Curvularia ramosa* (Bainier) Boedijn, and *H. tetramera* as *C. spicifera* (Bainier) Boedijn. The principal features of the new genus, *Curvularia*, are outlined.

Vienna

Academy of Sciences, December 17.

Frances G. Wick: Triboluminescence. Triboluminescence may be due to electrical discharges through the air around the crystal, or to radiation from centres in the crystal. These centres may be produced by X-rays, or they may be a characteristic of the crystal itself. In the latter case, they can be destroyed only by pulverizing the crystal.

Hanne Lauda: Decay of the latent image on the photographic plate. The decay of the latent image is greater at high temperatures, at high intensities of illumination, and for low densities.

Kasimir Graff: Colorimetric measurement of stars down to mag. 6·3 between 10° and 40° S. Decl.

S. Reisch: Galvanomagnetic method of measuring small displacements. The displacement is communicated to a coil of bismuth wire in a magnetic field, and the resulting change of resistance is measured.

G. Koller and H. Czerny: Limonin, the bitter principle of orange seeds.

Karl Federhofer: Normal vibrations of an axially compressed circular cylindrical shell.

K. Karas: Normal vibrations of non-uniform strings.

January 14.

F. Wessely and K. Jentzsch: Bitter principle of Columbo wood (5). Methylation of columbin.

Julius Pia: Tectonics of the Prague Dolomites (South Tyrol).

Alfred Jelinek: (1) Mechanics of periodic mountain winds. (2) Production of periodic mountain winds by thermal fluctuations.

A. Burger and E. Ekhart: Daily circulation of the atmosphere in Alpine regions.

Josef Priebsch and H. Kramer: Effect of temperature on cosmic rays. Observations at Hafelekar (2,300 m. above sea-level) with an unscreened Steinke apparatus show that there is a temperature effect with even the softest cosmic rays. The sign of the correlation coefficient, however, changes during the course of the year, being positive in summer and negative in winter. Observations with a screened apparatus give a negative correlation coefficient throughout the year.

F. Heritsch: Rugose corals from Timor, Djoulfa and the Salt Range, with notes on the stratigraphy of the Permian.

January 21.

Georg Koller and Hertha Russ: Constitution of solorinic acid.

K. W. F. Kohlrausch and R. Skrabal: Studies of the Raman effect (64). Cyclopentane and cyclobutane carboxylic acids and their derivatives.

Franz Bukatsch: Influence of the thermal waters of Bad-Gastein on the assimilation of carbonic acid by various water plants.

Herbert Haberlandt: Luminescence of fluorites and other minerals (3).

Emil Hauck: Cranial form of the coyote (*Canis latrans*).

Forthcoming Events

Monday, April 5

VICTORIA INSTITUTE, at 4.30.—Dr. E. W. G. Masterman: "The Dead Sea and the Lost Cities of the Plain".

SOCIETY OF ENGINEERS, at 6.—Inaugural Meeting. B. B. Tarring: Presidential Address.

Wednesday, April 7

INSTITUTION OF HEATING AND VENTILATING ENGINEERS, at 7—(at the Institution of Mechanical Engineers, Storey's Gate, S.W.1).—Dr. W. F. Bewley and E. S. Shoults: "Some Problems in the Heating and Ventilation of Glasshouses".

Thursday, April 8

ROYAL ASIATIC SOCIETY, at 4.30—(at the Royal Geographical Society).—Dr. Ernest Mackay: "Further Excavations in the Indus Valley".

Friday, April 9

OIL AND COLOUR CHEMISTS' ASSOCIATION, at 7—(at the Manchester Ltd. Restaurant, Cross Street, Manchester).—Annual General Meeting.

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

JUNIOR SCIENTIFIC OFFICER (physical chemistry) at the Torry Research Station—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, S W.1 (April 13).

HEAD OF THE ENGINEERING DEPARTMENT in the Hull Municipal Technical College—The Director of Education, Education Offices, Guildhall, Hull (April 17).

ASSISTANT (Grade III) in the Air Defence Experimental Establishment, Biggin Hill, Kent—The Superintendent (April 17).

LECTURER IN MATHEMATICS in University College, Dundee—The Secretary, The University, St. Andrews (April 30).

PROFESSOR OF GEOLOGY in the University of Bristol—The Registrar (May 1).

TWO ASSISTANT LECTURERS IN MATHEMATICS in the Royal Holloway College, Englefield Green, Surrey—The Principal (May 1).

RESEARCH ASSISTANT IN FRUIT PRODUCTS at Long Ashton Research Station—The Registrar, The University, Bristol.

ASSISTANT (Grade II) in the Royal Airship Works, Cardington—The Superintendent (April 9) (quote Ref. B.351).

Science and Politics in India: a Contrast

FROM year to year the Indian Science Congress, like the annual gatherings of the British Association, presents to the public both in and outside scientific circles a survey of recent contributions, chiefly by its own nationals, to the general stream of progress in scientific research and intellectual development. How far this is borne out by the proceedings of the recent Congress held at Hyderabad may be judged, in part, from the summaries of the presidential address and of the addresses of the sectional presidents which appear in another part of this issue of NATURE (see p. 638).

It is the privilege, as well as the responsibility, of certain of the sciences that they should bear more directly than others upon human well-being; and while it may be admitted that a too narrow concentration upon an immediately practical issue cannot but be harmful in the long run, in world conditions as they have now existed for some few years past, the activities of men of science have tended more and more to be submitted to the touchstone of their contact with current realities. Without in any degree abrogating the supremacy of the pursuit of knowledge for its own sake, it is more insistently and more constantly demanded that, as science in its origin arose out of practice, so as a return for the place now conceded it in the organization of modern life, it should contribute guidance in the diagnosis and solution of the problems of society.

Obvious as these reflections may seem, when applied to the conditions of European society, on turning to the consideration of conditions in India, they convey a warning and a moral. In contrasting, as is inevitable, the academic atmosphere of the Science Congress with that of the political arena, it is difficult to feel that the advantage in grasp of reality does not lie with the former.

The inauguration of the constitution followed on popular elections of a magnitude unprecedented, which gave a majority in six out of the eleven autonomous provinces, into which British India is now divided, to the Congress party. This sweeping victory, for it is nothing less, has been attributed to organization. This party alone, working on lines somewhat similar to those of a British election, was able to put directly before the rural elector the policy of reform and social amelioration which it proposed to pursue. When, however, the victorious party was brought to the practical test, it would seem, in the eyes of most reasonable individuals, to have proceeded to stultify itself by refusing to accept office in those provinces in which the electoral results had laid that responsibility upon it. The patent division of opinion on the wisdom of the course followed as between the leaders of the party and the general body of the Indian Congress, whatever attempts may be made to obliterate it later, gives to the whole situation an air of unreality, which unfortunately tends to confirm the view that with many, though not perhaps with all, the policy of agrarian reform, which has been so widely paraded, is no more than a pawn in the game.

The need for reform in India, and more especially agrarian reform, is so great and so insistent, that eventually, when once the elector has grasped the relation of his vote to political power and social reform, that power will be placed continuously and consistently in the hands of those who are able to give a practical demonstration of their grasp of what has been termed here the realities of the situation. At present, it is anticipated that Congress will attempt to throw upon the Government the onus of its failure to carry out its policy of social amelioration. In the recent election, many of the voters, it is stated, have suffered from the delusion that in voting for Congress they cast their vote against the Government. As was once said on another continent, "You cannot fool all the people all the time". The sincerity of Congress will be put to a severe test, if and when measures of reform are put forward by the coalition Governments set up in those six provinces where the Congress party is in the majority, and must needs vote for or against such measures of reform.

In the atmosphere of intrigue and legalistic argument which has followed the appointed day, it is something of a relief to turn once more to the findings of science and to enter upon the realm of fact. A rapid glance through the reports of the Indian Science Congress addresses now available will show how far the various branches of science, as studied in India and represented in these addresses, for the most part in the nature of general surveys, are alive to the vital problems of the population, of which the speakers themselves form part. It is indeed the vastness of this population which makes it essential that scientific methods of study should be applied to its problems. It has been pointed out on many occasions that even the functions of Government in India, now in the hands of the natives of India themselves, cannot be carried out efficiently without the knowledge of the varied racial and cultural discriminations revealed by anthropological studies.

To some extent provision for this has been made by the reservation of areas mainly inhabited by aboriginal or jungle tribes for the administration of the Governor; but the knowledge which must temper administration of the jungle tribes, must equally inform the whole of agrarian reform. No form of life is so impatient of change, so conservative, as the agricultural; and as Dr. Venkatraman pointed out in his presidential address, which deserves the careful attention of all who are interested in the future of India, there are few individuals throughout the whole of that sub-continent who are not affected more or less directly by the life and well-being of the Indian village. How vital the effect of the condition of the Indian village and the village agriculturist may be on the future of this great country is foreshadowed by the president of the Agricultural Section, when he points out that India at present produces two thirds only of the food-stuffs it requires. It is perhaps no rash prophecy to suggest that the future of India rests not with the party which shows itself most adroit and subtle in manipulating the political machine, but with that body of opinion which is most ready to accept the findings of science and to adapt them to the needs of the people in the amelioration of social and material conditions.

Air Raid Precautions

The Protection of the Public from Aerial Attack a Critical Examination of the Recommendations put forward by the Air Raid Precautions Department of the Home Office. By the Cambridge Scientists' Anti-War Group. Pp. 127. (London: Victor Gollancz, Ltd., 1937.) 2*s*. 6*d*. net.

IN this book, the authors—a group of anti-war scientists at Cambridge—have published a slashing attack on the recommendations put forward by the Air Raid Precautions Department of the Home Office for the protection of the public, and they offer scientific evidence to show that these measures are entirely inadequate.

The chief criticisms made in the book are as follows:

(1) 'Gas-proof' rooms prepared according to the instructions given in the Air Raid Precautions handbooks are not gas-tight; and the results of the tests that were made by the authors show that, assuming the air outside contains enough mustard gas to kill a man in an hour, it would penetrate such rooms in sufficient concentration to kill him in three hours. Besides, millions of people live in such conditions that they are unable to set aside a room as a gas shelter.

(2) A privately manufactured gas mask costing 17*s*. 6*d*. (not the type which the Government proposes to issue) was tested, and although it was found to be fairly satisfactory, the complaint is made that no mask can give complete protection against mustard gas because the latter affects the whole surface of the body.

(3) Incendiary bombs would be used in such numbers that the present fire brigade system would be inadequate to deal with the resulting fires.

(4) No protection for children under five years of age has yet been proposed.

Some of these criticisms seem to have been premature, for immediately after the publication of the book the Government announced its intention of organizing a fire-fighting force of 200,000 men, as well as auxiliary fire stations; and it also stated that a number of possibilities for the protection of young children against gas were being examined.

It is not clear why a privately manufactured gas mask was put through tests: this can scarcely have been in order to prove the ineffectiveness of the Government pattern; and to point out that no mask can give protection to the whole surface of the body from mustard gas vapour was surely unnecessary. No one, of course, would expect it to do so, any more than he would expect a bowler hat to keep his feet dry on a wet day. The recommendations made to meet the danger from mustard gas are to keep under cover so as to avoid direct contamination from the liquid sprayed from the air, and to remain in a home shelter, made as gas-proof as the circumstances permit, until the danger is over. What more can be expected? It would, of course, be possible to issue a complete suit of oilskins to every member of the public and to exchange them for clean ones whenever contamination was suspected; but this is a procedure which would not be regarded as reasonable or practicable by ordinary men.

It is true that in many of the poorer homes completely gas-proof shelters can only be provided with great difficulty; but that is no reason why the remainder should not be protected, or why the attempt should not be made to carry out the instructions so far as possible. The degree of protection can be increased in every case, whatever the circumstances, and it is not necessary to 'set aside' a room for the purpose, as anyone can see for himself by visiting the specimen gas-proof room at No. 17 Aldermanbury, E.C.

However, it is the results of the authors' experiments on the gas-proof rooms which I think will cause chief surprise and public interest. In the tests made, four rooms were 'sealed' in the manner recommended by the Home Office, and carbon dioxide gas was released in quantities calculated to produce concentrations of 5 per cent in each one; and it was found by measurement that half the gas had leaked out in 2¼, 2¼, 3¼ and 9¼ hours respectively. The authors conclude, but not by direct experiment with the same gas, that leakages into the room from outside would take place at the same rate, and that it occurs in little streams of air blowing to and fro in the small holes and tiny cracks in the plaster, bricks, doors, etc.

Theoretically, of course, gas can penetrate almost any material, but experiments showing the rate of leakage *from the open air into a gas-proof room* would have been of far greater interest to everybody who takes an interest in air raid precautions.

When questioned in the House of Commons about these remarkable results, the Government spokesman, after consulting his own scientific advisers, stated that the experiments themselves depended on academic assumptions, and that the deductions made from them had been interpreted on purely theoretical lines and had been proved to be open to grave criticisms. He went on to say that the experiments on which the Government recommendations were based had been conducted with actual war gases liberated under practical conditions, and with particular regard to the circumstances in which gas can be discharged from aircraft, and the measures proposed would be effective in affording a very great measure of protection to the public. He might have added that his own scientific advisers were the same men who had carried out thousands of experiments with poison gases during the Great War and had been engaged on chemical defence problems ever since. I have no connexion whatever with the Air Raid Precautions Department of the Home Office and am not concerned in its defence; but I am being consulted by numbers of business concerns who desire to organize their air raid precautions on the lines recommended by the Home Office: I believe that the recommendations are generally sound and reasonable, and it is important that public confidence in these measures shall not be shaken unnecessarily.

Many readers of NATURE will recollect the steps that were taken during the Great War to safeguard the shelters in the forward areas against gas: gas attacks were a daily experience, especially during the later stages of the War, and every shelter and dugout in the forward area was 'gas-proofed' precisely in the manner recommended by the Home Office—that is, by stopping cracks, hanging up curtains, providing 'air locks', and so on; and these measures were proved to be so effective in actual practice by all the armies engaged that in planning gas attacks with shells, clouds from cylinders, or projector and trench mortar bombs, no attempt was made to employ tactics designed to penetrate the protection thus afforded. (The group of Cambridge scientists would perhaps suggest that a still greater degree of safety could have been obtained by stopping the war altogether.) The victims of gas attacks were for the most part men who were caught unawares, or were compelled by the nature of their duties to remain out in the open; and this would also be the experience of civil populations subjected to aerial gas bombardment. Some of our dense gas clouds penetrated far behind the German front line, but because of the precautions adopted we never heard of civilians suffering serious inconvenience on account of them. For example, vegetation in the gardens of Lille was often bleached by our gas, but the inhabitants were warned of its approach by the ringing of bells, and they took refuge in the top rooms of their houses and closed all the windows and doors. Nor did these gas attacks cause them sufficient discomfort to create resentment: the wife of the mayor of one of these towns, after its reoccupation by the British army, told us that she had always had German officers billeted on her and that they feared gas more than anything else: "Give them gas all the time," she said, "and then more gas."

The authors of this book in their destructive criticism seem to ignore the fact that some degree of protection is better than none, and their conclusions would carry greater conviction to the ordinary man in the street but for the suspicion that scientific theories may sometimes be perverted for political ends.

As one who has had, perhaps, more experience of the stark realities of gas warfare than anyone else, and has studied the reports of thousands of field tests carried out by British, French and American gas experimenters as well as witnessed many of the tests personally, I do not believe that anything approaching a concentration of 5 per cent of gas can be established in the open air by an aerial or any other kind of bombardment. Such a bombardment, to have any appreciable success, would have to be sustained and systematic, and I cannot believe that it could continue for a period of three hours over, say, London without interference. Anything less would be ineffective except in the most exceptional atmospheric conditions: in comparatively open spaces, such as the neighbourhood of Imperial Chemical House, gas would drift away and be dissipated at a rate varying with the prevailing air currents; while in circumstances most favourable to it, say, in the City, with its tall buildings and narrow courts and lanes, the dispersion of gas clouds by movements of the air would be delayed, but most of the blocks here are well provided with basements and strong-rooms which are shelters within a shelter, so that even if all the windows were shattered, gas in any harmful quantity could be excluded by gas-proofing the staircases and lift shafts and by providing air-locks in the manner recommended. As for gas penetrating brick and concrete walls from the open air outside, this is no doubt theoretically possible, but in my own shelter, provided that the sealing is carefully carried out, I would be content with a good strong wall-paper—let alone the brick wall to which it is attached.

This book can do nothing but harm. It suggests no better defensive measures than those recommended by the Home Office, while it is calculated to destroy confidence in them and to create panic. Nor can it have the slightest effect in stopping war: there is probably no reasonable individual in Great Britain who would be willing to make war at the present moment, except in the case of absolute necessity imposed upon us by the 'mad dogs' of Europe; and if that necessity should arise, let us hope that we will not be deterred from our duty to ourselves and to posterity by contemplating its horrors—still less by exaggerating them.

C. H. Foulkes.

Maps through the Ages

The World in Maps:
a Study in Map Evolution. By Prof. W. W. Jervis. Pp. 208+4 maps. (London: George Philip and Son, Ltd.; Liverpool: Philip, Son and Nephew, Ltd., 1936.) 7*s.* 6*d.* net.

DESPITE the increasing interest in maps now manifest, no one in Great Britain has yet undertaken a really comprehensive work on all sides of the subject, such as was attempted in Germany some years ago by Max Eckert. The present modest effort makes no pretence of filling the gap, its aim being rather to provide the intelligent layman with a general introduction to the subject. Apart from the width of the survey, it does not go greatly beyond previous attempts of a popular kind, and it, of course, has no claim to vie with the excellent books on the technical side of map-making now available.

The arrangement of the book shows some lack of system. It begins with chapters on practical matters, such as the indication of scale and direction, projections, topography and relief, with an attempt to trace the evolution of method from early times. Then follow two chapters on the maps and map-makers of medieval and early modern times, while the last part is concerned with requirements and methods of map-production at the present day, including a chapter on national map departments. The historical side of the subject is kept prominently in view through most of the book, and it is perhaps permissible to deal chiefly with this in the following comments.

The author certainly displays a fairly wide acquaintance with the maps and methods of the past; but he is too often betrayed into statements which show that his knowledge is but superficial, and that he has imperfectly digested what he has taken from other writers. Also he has missed some of the more important authorities on certain points; for example, his perfunctory treatment of the history of the prime meridian takes no account of Mr. W. G. Perrin's excellent summary of the subject. In places he seems to have reproduced the jottings of his note-book with little attempt at arrangement or revision. Thus in Chapter viii there are two inconsistent references, separated by a few pages, to Christopher Saxton's large map of England, one passage having evidently been written before, the other after, the acquisition by the British Museum of a unique early copy. A good many statements are misleading, to say the least, and the following instances are but a few out of many. It is scarcely true that Münster's maps were standard for a century; that Mercator invented the Southern Continent; or that Blome was a publisher "of very high repute". On reading that Moses Pitt's English Atlas was a "good attempt to rival Dutch Cartography", one would scarcely realize that the actual basis was entirely Dutch. Instances of slipshod language abound. We find Portolani, Reinels treated as singular, Mappa Mundi as plural, and there are many misspellings of names—Duningsby for Dunningley, Wauermann for Wauwermans, Zugler for Ziegler, Philpott for Phillott, and others. The chronological list of maps makes an imposing show, but it contains many errors, including the astonishing statement that the Rome map of the British Isles of 1546 was "made by Speed"—then unborn. Both in this list and the extensive bibliography, better judgment might have been shown in selecting the entries.

The chapters on modern map-making are not perhaps open to such serious criticism, and the views expressed seem generally judicious, as when the advantage of the 'dot' system to represent distributions is stressed. This part may be of use to those desiring a general view of the subject without going deeply into it.

One can only regret that the author should have been so hasty in publishing his notes, for he would no doubt be capable of better things with further study and more care to verify his references. The publishers have added a series of outline sketches of early maps, mostly taken from previous publications of the firm, and not linked to the text by any commentary. E. HEAWOOD.

Probability: Theory and Applications

Elements of Probability
By Prof. H. Levy and L. Roth. Pp. x + 200. (Oxford, Clarendon Press; London: Oxford University Press, 1936). 15*s*. net.

THIS is an interesting book. Its main interest lies in the endeavour of the authors to keep throughout a clear distinction between three different fields of study, all in some way interrelated and each forming a partial approach to the general problem of probability: (1) a mathematical theory (the authors add, "of arrangements" which I should prefer to omit), (2) the frequency of actual occurrences of an event in repeated trials and (3) the psychological expectation of a participant. The authors are primarily interested in (1), and assume the definition of mathematical probability as follows:

"If there is a group of N letters consisting of n letters a_1, n_2 letters a_2, ... and n_r letters a_r, the probability of a letter specified as belonging to the class $a_1, a_2, \ldots a_r$ being a letter a_s is n_s/N."

In other words, the probability of an object A, possessing a property B, is defined as the proportion of those objects A which actually possess the property B.

I am not exactly clear about the opinions of the authors given on pp. 22–23. One way of interpreting them is that it is impossible to build up a mathematical theory of probability both rigorous and useful, starting with some conveniently formulated axioms forming a mathematical model of what is known or assumed about the processes of mind, connected with expectation. If the authors mean to affirm this, I cannot share their opinion.

Practical applications of the theory of probability built up on the above definition require the construction of a mathematical model of the practical situation studied, involving a class of objects subdivided into several sub-classes.

The definition quoted is, of course, not new. It is adopted in many recent publications and is taught in many lecture theatres. But usually it is soon forgotten and the succeeding development of the theory is carried out in terms of 'experiments', 'frequencies', etc. It is true that such expressions, having no immediate relation to the definition, stand for something else, reducible to this definition. However, the process of reduction is not so easy as one may imagine, and the student is frequently led to a confusion of (1) with (3) or with (2) respectively.

It may be useful to illustrate this point. Suppose that a bag A contains three balls, one with 1 and two with 2 written on them. Besides the bag A there are two more bags, one distinguished by the number 1 and the other by 2. The bag 1 contains five balls, of which one only is black. The bag 2 contains seven balls of which exactly four are black. We perform an experiment consisting in two drawings of balls. First we draw a ball from the bag A, next we draw a ball either from bag 1 or from bag 2, according to what was the number on the ball drawn from A. The question asked is, What is the probability of ultimately drawing a black ball? If this problem were given to an average undergraduate, he would probably immediately produce the correct answer, 47/105. If he started his studies in probability with a definition similar to that given by the authors, he would agree that this number represents the "proportion of things A having the required property B". But if the definition in terms of the proportion was not followed by a special training in distinguishing between (1), (2) and (3), he would find difficulty in explaining what exactly are these "things A", what may be their total number and what is their "property B". Confronted with these questions, the student would be surprised to discover that he was not clear about the whole problem which seemed to be so simple. It is this surprise, contrasted with the quiet attitude to the obtained result 47/105, which indicates that in the process of reaching it, the student had in his mind not the definition of probability assumed, but some more or less vague ideas concerning frequencies or psychological expectation: the confusion of (1) with (2) or (3) which the authors try to help to avoid.

The book under review is very valuable because the authors consistently apply the definition quoted so as to accustom the reader to the basic idea involved. They go so far as to reword the usual theorems of summation and multiplication of probabilities, Bernoulli's Theorem, etc., constantly referring to the idea of proportion. However, the usual wording, in terms of experiments, has become customary partly because of its convenience. Therefore, after training the reader for a period, the authors return to the traditional terminology, pointing out that this should be accepted as a convention.

It is difficult to say whether the new wording of usual theorems introduced by the authors is a success. I personally use the definition adopted by the authors, and I recognize the necessity of rewording the theorems, but I use another way of speaking, in terms of "things A" and their "properties B". Which of the two is more convenient is probably a question of taste, but it may be useful to give an example. The multiplication theorem as given by the authors, reads:

"If P_1 is the probability that an object belongs to the sub-class a_1 of classes $a_1, a_2, \ldots . a_r$ and P_1, is the probability of its belonging to the sub-class A_1, of the classes $A_1, A_2, \ldots . A_s$ (which are exclusive to $a_1, a_2, \ldots, a_r$), then the probability that it belongs to the combined class a_1A_1, is p_1P_1."

It seems to me that the following statement is somewhat simpler:

"The probability, $P\{BC/A\}$, that an object A possesses the two properties B and C is equal to the probability, $P\{B/A\}$, that it possesses the property B, multiplied by the probability $P\{C/AB\}$ that an object A which possesses the property B possesses also the property C."

Incidentally, this wording makes it easy to introduce the conception of stochastic dependence which is somewhat neglected by the authors.

The original definition, applicable in cases when the set of objects considered is finite, is later extended to cover the case of continuity. The obvious method of extention in terms of the measure of the sets of points has not been adopted by the authors, probably because of the elementary character of the book.

Two long chapters are given to the theory of arrangements. In another two chapters, occupying altogether 100 pages, the authors discuss various problems relating to statistics. One of these, concerning selective sampling (pp. 146–165), seems to deserve special attention of the reader. Throughout the book, there are many interesting examples and illustrations.

I have noticed a few minor lapses. Thus, for example, after having shown accurately that the variance of the binomial is npq, the authors describe (page 142) the expression $\sqrt{npq}$ as the mean value of $|r-np|$, which is, of course, not exact.

In conclusion, I should like to mention a short but very interesting historical introduction, preceding the main part of the book. It brings out how all aspects of probability are historically interlocked in scientific method and social practice, and so presents a united background against which the various partial analyses can be appraised.

J. NEYMAN

Faune de France

30: Cestodes. Par Prof. Ch. Joyeux et Dr. J. G. Baer. (Fédération française des Sociétés de Sciences naturelles: Office central de faunistique.) Pp. iii+613. (Paris: Paul Lechevalier et fils, 1936.) 200 francs.

TAPEWORMS are psychologically nasty animals, but they are relieved by attractive life-histories. The elongated worm with its many segments lives in the gut of vertebrates and breaks off its hind divisions (proglottides), passing them out with the fæces of the host. These are full of ripe eggs which are shed on to the ground or into the water. Then comes along some animal which swallows them. Reaching its stomach, they bore through its wall to rest as rounded bladder worms (cysticerci) in its body, where they may swell up forming cysts of fluid, into which may project one or more heads. They, if eaten by their first host, attach themselves by their heads to its gut wall and bud off segments to form elongated tapeworms, which in turn repeat the life-cycle. Occasionally one host serves for both worm and cysticercus; many have both stages in vertebrates, but probably the majority have their cyst stage in some invertebrate, species being enumerated in jelly-fish, worms, crustaceans, insects and molluscs.

Settled rules as to these and other biological matters will be sought in vain in this catalogue of more than 2,000 species, for the life-histories of many are unknown, and this number probably does not represent half the species found in France. Clearly allied species of vertebrates commonly have the same tapeworms; but this may well be a question of similarity of food, since quite distantly related animals feeding on the same food often have the same worms. We might like to think of the evolution of the worms and of their hosts going on together, but, while encouraged by the unsegmented and presumably primitive *Gyrocotyle* and *Amphilina* being restricted to *Chimaera* and the sturgeon, this does not seem to be the case. *Gyrocotyle*, anyhow, is exceptional, as it is often found in the mud frequented by *Chimaera*.

In any event, this monograph, when studied, suggests all kinds of problems, both physiological and evolutionary, and should be in the reference library of every zoological and medical department. It is illustrated by 569 most useful line illustrations and gives all the necessary data both as to the parasites and their hosts.

Beiträge zur Mineralogie von Japan

Begründet von T. Wada. Neue Folge, 1. Herausgegeben von T. Ito. Pp. vii+xviii+259. (Tokyo: Imperial University, 1935.)

NOT a great deal has been written about the minerals of Japan. The earliest information about them is contained in the treatise written by the late Prof. T. Wada, of which an English translation by T. Ogawa appeared in 1904. A second edition followed, but only in Japanese. Inasmuch as supplements speedily became necessary in order to keep the information up to date, Prof. Wada began in 1905 a series, under the general title of "Beiträge zur Mineralogie von Japan", which was to consist of original papers on Japanese minerals written in either German or English; the latter language, however, was invariably selected by the contributors. The series came to an end in 1915, and Prof. Wada died in 1920.

The present volume is intended by the author, the director of the Mineralogical Institute of the Imperial University of Tokyo, to be the first of a new series of contributions, which ultimately will be used in the preparation of the third edition of Prof. Wada's treatise. Despite its German title, the text is in Japanese, but there is a good summary in English, and throughout the text ordinary letters and numerals are used to denote the crystal faces, so that the reader need not know Japanese to cull information from the pages. The volume is dedicated to the memory of the late N. Fukuchi, who was lecturer in mineralogy at the Imperial University, and did much work on Japanese minerals; his portrait forms the frontispiece.

The volume comprises seventy-six original contributions, together with an introduction descriptive of the two-circle method of measuring crystals and denoting the positions of their faces. There are two indexes: in Japanese with English equivalent, and vice versa. The summary is provided with its own pagination and index. A map showing the localities mentioned adds greatly to the value of the volume.

Les rites secrets des primitifs de l'Oubangui

Par A.-M. Vergiat. (Bibliothèque scientifique.) Pp. 212+32 plates. (Paris: Libr. Payot, 1936.) 25 francs.

M. VERGIAT, an experienced observer and skilled recorder with the camera of native life and custom in more than one part of Africa, has taken advantage of the opportunity afforded by a botanical excursion to the French Congo to investigate the esoteric beliefs and rites of the tribes of the region. More fortunate than most Europeans who attempt, usually with indifferent success, to penetrate these *arcana*, he won the confidence of a native sorcerer, who accompanied him when he was collecting botanical specimens, and passed on to him much of his knowledge. For this indiscretion, it would seem, the informant paid the penalty with his life. In the meantime, however, the author had not only acquired a detailed knowledge of the religious and spiritual beliefs of the people, but also had secured full particulars of the initiation ceremonies and circumcision rites practised at puberty, as well as of the ceremonial of admission into the principal secret societies. His account of the female ceremony of clitoridectomy, which is illustrated by photographs, is exceptionally full. In recording such matters as these, the author no doubt has good reason for making no explicit statement as to how such valuable detailed information was obtained.

As a botanist, M. Vergiat was much interested in the plants used in native magic and medicine. Of these, he gives detailed lists with identifications.

Pigments Associated with the Fatty Tissues of Plants and Animals*

By Prof. I. M. Heilbron, F.R.S., and A. E. Gillam.

THE fat-soluble pigments (lipochromes) which form the subject of the present survey, comprise a sharply defined class of yellow to violet-red compounds not only widely distributed in flowers and fruits, but also met with throughout the whole of the animal kingdom. In virtue of the fact that the first of these pigments to be obtained in crystalline form was isolated from carrots, they are commonly known as carotenoids. As a group they are characterized further by their insolubility in water, by their sensitivity to atmospheric oxygen, which readily bleaches them, and by the deep blue coloration which they give with sulphuric acid. In addition to its occurrence in the carrot, the most typical member of the group, carotene, is invariably found with chlorophyll in all green foliage, being also associated with another yellow consitituent to which the name xanthophyll was originally given. Despite the wide distribution of these two pigments in Nature, it must be emphasized that they, in common with other members of the group, occur only in very minute amounts in living matter. Thus the fresh carrot contains only about 0·1 per cent of carotene, whilst in fresh grass the order approximates only to 0·01 per cent carotene and 0·02 per cent xanthophyll.

Although carotene was originally isolated so early as 1831, the first work of real chemical significance in this field was due to Willstätter and his collaborators who, during the years 1906–14, effected the isolation of several of the more important carotenoids in crystalline form and established their empirical formulæ. It was thus found that carotene was a hydrocarbon having the formula $C_{40}H_{56}$ and that it was isomeric but not identical with lycopene, the pigment of the ripe tomato. Similarly, leaf xanthophyll was shown to have the formula $C_{40}H_{56}O_2$ and to be very similar to, if not identical with, the yellow pigment of egg yolk, then known as lutein. Another interesting member characterized at this period was a still more oxygenated pigment, fucoxanthin, $C_{40}H_{56}O_6$, which was obtained from *Fucus vesiculosus*, a member of the brown seaweeds.

The further development of the chemistry of the carotenoids languished until 1928, when Zechmeister, Cholnoky and Vrabely proved, by means of quantitative catalytic hydrogenation, that carotene contains eleven ethenoid linkages giving rise to a saturated perhydrocarotene of formula $C_{56}H_{78}$, from which it can be deduced that the pigment itself must contain two cyclic systems. In a similar manner, Karrer and Widmer ascertained that lycopene absorbs thirteen molecules of hydrogen yielding a paraffin hydrocarbon $C_{40}H_{82}$, a result which shows that the pigment must by acyclic.

The next important development in our knowledge of the carotenoids came about when Kuhn, Lederer and Winterstein reintroduced the method of chromatographic analysis, as a means of separating and purifying the individual pigments of plant tissues. So early as 1906, the Russian botanist Tswett had shown that substances such as calcium carbonate or powdered sucrose, when packed in vertical columns, have the power of absorbing pigments from their solutions in non-polar solvents such as light petroleum, and that with a mixture of pigments the constituents orient themselves as coloured zones or bands at various positions on the column, depending upon the strength of adsorption of the individual components. On applying this technique to ordinary carrot carotene, it was found that the pigment could be separated into two distinct components, the optically inactive β-carotene and the dextrorotatory α-carotene. The former is adsorbed above the latter when the chromatogram is developed by washing with light petroleum. Of these two isomerides, β-carotene generally predominates, although in palm oil carotene there is as much as thirty per cent of the α-isomer.

Shortly after this discovery, the presence of a third isomer, γ-carotene, was disclosed under conditions which serve to emphasize the elegance of this technique, which more than any other has contributed to the recent rapid progress in this field. Commencing with 35 gm. of commercial crystalline carotene (equal to about 6 cwt. of raw carrots) Kuhn and Brockmann subjected it to chromatographic adsorption and observed a small pigmented zone above that of the β-carotene in the column. After many adsorptions they ultimately succeeded in isolating from the collected upper zones 34 mgm. of the γ-isomeride, with which amount they were able to study its physical, chemical and biological properties and so advance a structural formula for the compound—a remarkable example of the delicacy of modern chemical technique.

---

* Expanded from a Friday evening discourse at the Royal Institution delivered by Prof. I. M. Heilbron on February 12.

A further interesting and important point in connexion with chromatography is that not only does it provide us with a readily accessible method for the isolation of minute amounts of specific pigments, but it provides in addition a means of differentiating various classes. Thus the hydroxylated carotenoids (or xanthophylls as they are now generally called) are all much more strongly adsorbed than the hydrocarbon pigments ; moreover, the degree of adsorbability is proportional to the number of hydroxyl groups.

Another criterion determining the position of adsorption in the column is the number and disposition of unsaturated linkages. This is illustrated by the fact that lycopene, γ-carotene, β-carotene and α-carotene are retained on the adsorption column in descending order, which corresponds partly with the total number of ethylene linkages in their molecules and partly with the length of the conjugated system. This latter effect is evidenced in the β- and α-carotenes, both of which contain eleven double bonds. In the former, however, these are all conjugated, whereas in α-carotene only ten are so arranged. Table I (due to Winterstein) illustrates these general principles :

TABLE 1.

RELATIVE ADSORBABILITY OF VARIOUS CAROTENOIDS FROM LIGHT PETROLEUM SOLUTION

Strongest adsorbed	Fucoxanthin	$C_{40}H_{56}O_6$	Alcohols	$CaCO_3$
	Violaxanthin	$C_{40}H_{56}O_4$		
	Taraxanthin	$C_{40}H_{56}O_4$		
	Flavoxanthin	$C_{40}H_{56}O_3$		
	Zeaxanthin	$C_{40}H_{56}O_2$		
	Lutein	$C_{40}H_{56}O_2$		
	Rhodoxanthin	$C_{40}H_{50}O_2$	Ketone	Al_2O_3
	Physalien	$C_{72}H_{116}O_4$	Esters	
	Helenien	$C_{72}H_{116}O_4$		
	Lycopene	$C_{40}H_{56}$	Hydrocarbons	
	γ-Carotene	$C_{40}H_{56}$		
Weakest adsorbed	β-Carotene	$C_{40}H_{56}$		
	α-Carotene	$C_{40}H_{56}$		

The separation by chromatographic methods alone of a complex mixture of pigments such as is often met with in Nature, is an extremely complicated procedure. Fortunately, however, it can frequently be simplified by carrying out a preliminary partition between two immiscible solvents such as light petroleum and 90 per cent methyl alcohol, when it is found that hydrocarbon pigments and esters pass into the petroleum layer (epiphasic pigments), whilst those pigments containing free hydroxyl groups pass preferentially into the alcohol (hypophasic pigments).

Another physical property of great diagnostic value in the study of carotenoids is that of light absorption. It is a well-established principle that with an increasing number of conjugated unsaturated linkages in a molecule, the absorption maxima become progressively displaced towards longer wave-lengths. This is exceptionally well exemplified among the carotenoids, which are characterized by well-defined triplet absorption bands, and the closest possible correlation exists between the position of the bands and the number and character of the conjugated centres. These effects are shown in Table 2.

TABLE 2

EXAMPLES OF THE EFFECT OF UNSATURATION ON THE ABSORPTION SPECTRA OF TYPICAL CAROTENOIDS

Carotenoid.	Number of Double Bonds. *Conjugated*	*Unconjugated*	Absorption maxima in CS_2 (mμ)	
Rhodoxanthin	14(2C=0)	0	564	525
Lycopene	11	2	548	507
γ-Carotene	11	1	533	496
β-Carotene	11	0	518	485
α-Carotene	10	1	508	477
Violaxanthin	9	1	501	469

It is beyond the scope of this article to attempt to describe in detail the elegant investigations of Karrer, Kuhn, Zechmeister and their respective collaborators, which have culminated in the elucidation of the constitution of these pigments. The formulæ for the four hydrocarbon pigments are given on p. 614, and these represent the fundamental structures upon which a large number of naturally occurring oxygenated derivatives are built.

In Table 3 the hydrocarbons and the simpler xanthophylls which correspond to them are enumerated.

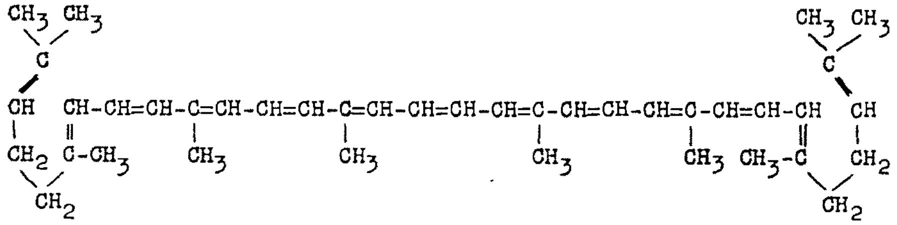
TABLE 3

RELATION BETWEEN THE HYDROCARBON CAROTENOIDS AND THE SIMPLER XANTHOPHYLLS

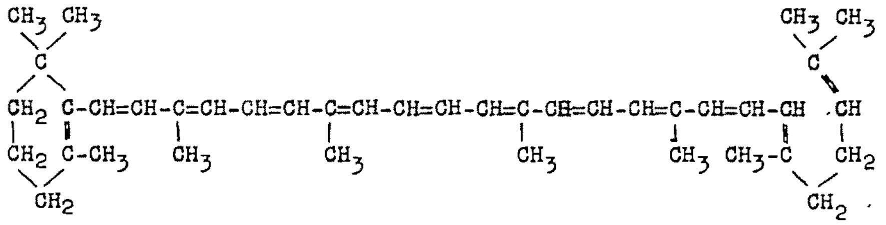
Hydrocarbon	Monohydroxy Derivative	Dihydroxy Derivative
$C_{40}H_{56}$	$C_{40}H_{56}O$	$C_{40}H_{56}O_2$
Lycopene	Lycoxanthin	Lycophyll
γ-Carotene	Rubixanthin	—
β-Carotene	Kryptoxanthin	Zeaxanthin
α-Carotene	—	Lutein

Of the various possible types of oxygenated carotenoids, alcohols are of most frequent occurrence, and of these it will suffice to mention a few of the more common. Leaf xanthophyll, which consists mainly of a pigment having the formula $C_{40}H_{56}O_2$, has been re-named lutein, and is actually a dihydroxy derivative of α-carotene, with which it is spectographically identical. The pigment of egg yolk, originally called lutein, has now been separated into lutein proper (leaf xanthophyll) and an isomeric pigment, zeaxanthin. This is a dihydroxy β-carotene occurring in small quantity in many leaves, berries and fruits, but most readily isolated from maize. The acyclic analogue lycophyll has recently been isolated from several species of *Solanum*. Of other xanthophylls mention may be made of flavoxanthin $C_{40}H_{56}O_3$, the yellow buttercup pigment, violaxanthin $C_{40}H_{56}O_4$, the yellow pansy pigment, and the isomeric taraxanthin from the dandelion.

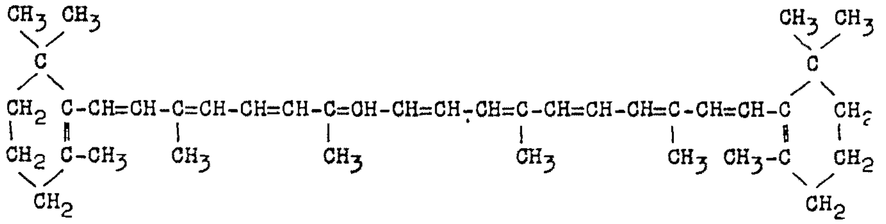
The pigments so far considered have all been representatives of the higher forms of plant life, but among the Cryptogams, lipochrome pigments also abound, especially among the Algæ. Recent work in this field carried out in the University of Manchester, has brought to light some interesting generalizations. It would seem that whereas carotene is common among all algal orders exactly as in the higher plants, a definite differentiation of pigment is met with in the various species of Algæ. As examples of this, the Phæophyceæ (brown Algæ) are all characterized by the presence of fucoxanthin, a pigment which is very easily distinguished by the beautiful colour which it gives with 25 per cent hydrochloric acid. Again, among the Cyanophyceæ (blue-green Algæ), a specific pigment, myxoxanthin, is seemingly common to all members of the group.



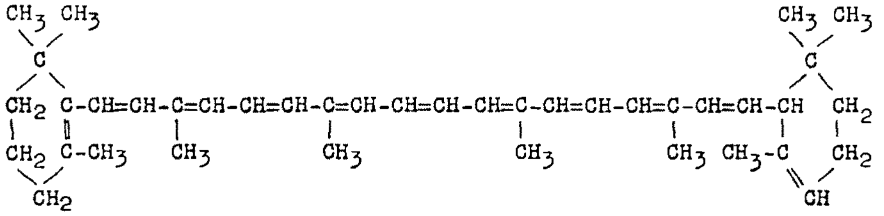
Lycopene



γ-Carotene



β-Carotene



α-Carotene

As already mentioned, the carotenoids are by no means confined to the plant world, but are met with throughout the animal kingdom, from the lowest types of life to man himself. Among the vertebrates, the carotenoids are absorbed from the food and consist therefore mainly of carotene and lutein. Zechmeister and his co-workers have recently made a close study of this subject, and have shown that certain interesting differences are to be observed among the higher animals; thus although the carotene-lutein ratio in grass is of the order 1 : 2, both the cow and the horse preferentially absorb carotene to the almost complete exclusion of lutein. Man, on the other hand, evinces no especial preference, and both pigments are found to be present in human blood serum, whilst in the pig, cat, dog and the rodents no carotenoids appear to be retained. The early experiments of Palmer have shown that birds accumulate xanthophylls, to the almost complete exclusion of carotene, in their blood and body-fat as well as in their egg yolk. It has also been shown by Brockmann and Völker that the yellow colour of the plumage of canaries is due to the presence of lutein, or a closely related transformation product, and is produced solely when this pigment is present in the food, for in its absence the feathers become white.

Turning now to the invertebrates, here a great diversity of carotenoids, distinct from those found in plant tissues, are met with. Among the Crustacea, the characteristic bluish colour of the live lobster is due to the presence of a labile chromoprotein, which breaks down at the temperature of boiling water liberating the free lipochrome, astacene. This pigment, which is a tetra-keto-β-carotene, $C_{40}H_{56}O_4$, is very widely distributed in aquatic animals, being found in the skin of goldfish, in starfish, in the flesh of salmon, etc.

Among other marine forms, the sea anemones also owe their brilliant colours to specific carotenoids of complex character; thus *Actinia equina* contains a very beautiful purple pigment, actinoerythrin, which is an ester; the free violerythrin, $C_{40}H_{58}O_4$, is characterized by the intense blue colour of its solution in organic solvents. Again, from *Anemonia sulcata* a still more oxygenated pigment, sulcataxanthin, $C_{40}H_{52}O_8$, has been isolated.

Carotenoids have also recently been discovered in bacteria. Thus the purple rhodovibrio bacteria have been shown by Karrer to contain a series of probably six closely related pigments. Of these, rhodoviolascin, $C_{42}H_{60}O_2$, has been clearly characterized, and constitutes the first known methylated xanthophyll.

(To be continued.)

The Earthquake Research Institute of Japan

By Dr. Charles Davison

THE first Japanese earthquake known to us occurred in A.D. 416. For many years, the chronicle of its successors is naturally incomplete, but, with the nineteenth century, the entries become more frequent; how full they are is evident from Omori's studies of the after-shocks of the great earthquakes of 1830, 1847 and 1854. With the Yokohama earthquake of 1880, the investigation of the earthquakes on modern lines began. Though not of great strength, the shock was the first to arouse the interest of the English professors then living in Tokyo. A few months later, the Seismological Society of Japan was founded by the late Prof. J. Milne, and the admirable work done by him and his colleagues during the next twelve years was continued and expanded by the Imperial Earthquake Investigation Committee and the Earthquake Research Institute.

For the next change, another earthquake was responsible, that of Mino-Owari on October 28, 1891. The widespread damage caused by this great earthquake led to the foundation in the following year of the Imperial Earthquake Investigation Committee, the aims of which were of a practical nature, namely, to discover, if possible, whether the occurrence of earthquakes can be foreseen, and to devise methods of lessening their destructive power. How great was the advance along the second line and how valuable were the contributions of the Committee towards our knowledge of earthquakes in general is clear from the journals that it published and especially from the long series of memoirs that appeared under the name of Prof. F. Omori.

In 1926, shortly after the publication of the valuable reports on the great earthquake of 1923, the Investigation Committee ceased to exist, and its place was taken by the Earthquake Research Institute, with its home, as before, in the Imperial University of Tokyo. Why the change was made is not quite clear, unless it was felt that the work could be carried on more satisfactorily by younger men. The aim of the new Institute was stated to be scientific research on earthquakes. The first director was Prof. K. Suyehiro, who, on his death in 1932, was succeeded by Prof. M. Ishimoto. In its first year, the staff of the Institute consisted of thirteen members, several of whom had been connected with the Investigation Committee. During the last five years, the number of active members of the Institute was thirty-nine.

When the volumes issued by the Institute are compared with those of its predecessor, two welcome features are manifest—the extraordinary increase in the number of students of pure seismology, and the large number of memoirs written by two or more authors. During the first three years, the new *Bulletin* appeared twice a year, but in 1929 and after it was issued quarterly. By the end of 1936, fourteen ordinary volumes were completed, as well as three supplementary volumes containing papers and reports on the Sanriku seawaves of 1933, the typhoon of 1934, and the Formosa earthquake of 1935. Altogether, the seventeen volumes include 504 memoirs by ninety authors and number 7,646 pages with 1,023 plates. In the first four volumes, three out of every five papers were written in Japanese with summaries in English or French; but, in the last ten volumes, the ratio, fortunately for Western readers, fell to one in five.

Since the Institute began its work, there have been four great earthquakes in the Japanese empire—those of Tango in 1927, Idu in 1930, Sanriku in 1933 and Formosa in 1935—and, on each of these, series of valuable reports are printed in the *Bulletin*. Other earthquakes of less, but still destructive, intensity are also described in one or several papers, such as the Etigo earthquake of 1927, the Kaga earthquake of 1930, the Noto earthquake of 1933, the Idu earthquake of 1934, the Siduoka earthquake of 1935 and the Kawati-Yamato earthquake of 1936. These are probably the most important Japanese earthquakes of the years 1924–36, but Western readers would be grateful if they could be supplied with an annual list of all the stronger Japanese earthquakes.

For an important section of the earthquakes, those that are sensible in Tokyo, the Institute provides valuable quarterly *Seismometric Reports*. In 1924, the capital was surrounded by a network of nine seismological stations at various distances up to 64 miles. By 1935, the number of stations had risen to thirteen, all within 83 miles of Tokyo. From the durations of the preliminary tremors at three or more stations, the position of the epicentre and the depth of the focus can be determined. During the twelve years 1924–35, the *Reports* contain the records of 766 earthquakes; thus, on an average, one earthquake was felt in Tokyo every 5·7 days. Of the total number, the position of the epicentre was estimated in 699, or 91 per cent, and the depth of the focus in 553, or 72 per cent. All the epicentres are plotted on small maps, annually for the first seven years, quarterly for the last five. Most of the shocks were of slight intensity, and only four reached destructive strength at any one of the stations.

Similar observations, though on a less extensive scale, are made whenever a great earthquake occurs. Immediately after the Tango earthquake of March 7, 1927, members of the Institute were dispatched to the central district, and portable tromometers were installed at three stations near the epicentre on March 11 and 12, by which 1,327 after-shocks were recorded by the end of July 1928. Of these shocks, many were very slight, but 520 were registered at three stations, and the position of the epicentre was found for 482 shocks, and the depth of the focus for 477. Again, soon after the remarkable earthquake swarm at Ito began in the spring of 1930, tromometers were erected at five surrounding stations and, later on, near the adjacent centre of the Idu earthquake of November 26, 1930. In both series, the earthquakes were so numerous, several hundreds sometimes occurring on one day, that no detailed list of them has been published.

In both the Tango and Ito districts, tiltmeters, designed by the present director, Prof. M. Ishimoto, were erected in the neighbourhood of the tromometers. It was found that, before even moderately strong shocks, a perceptible tilting of the ground was revealed by these instruments. Thus, it is not too much to hope that, before many years are past, such records may provide trustworthy forecasts of coming destructive earthquakes.

In no other country have re-surveys after great earthquakes been carried out with such frequency and method as in Japan. At the suggestion of the Institute, new lines of levelling were made by the Land Survey Department of the Japanese Army across the central areas no less than five times after the Tango earthquake of 1927 and the Ito earthquake swarm of 1930, and in many districts without the accompaniment of recent earthquakes. Re-triangulations of the central areas have been carried out after the Kwanto earthquake of 1923, and the Tango and Idu earthquakes. The repeated levellings in some districts have shown that the crust is broken up into blocks, 4–6 miles across, and that each block moves more or less independently of its neighbours. The mapping of the blocks is perhaps most detailed in the Boso peninsula and the Kwanto plain, both forming parts of the region displaced during the great earthquake of 1923.

Some of the phenomena of earthquakes have been closely studied, especially the remarkable seawaves of the Sanriku earthquake of 1933 and its predecessors, as well as the *kase-tunamis* or non-seismic seawaves that were raised by the great typhoon of 1934, and these studies have suggested precautions that, on future occasions, may lead to the saving of many thousand of lives. Luminous phenomena have been so widely observed with the Idu earthquake of 1930 and the Sanriku earthquake of 1933 that little doubt can now be felt as to their reality or their connexion, direct or indirect, with the earthquakes. Many curious and interesting observations have been recorded on the abundance of fishes caught after earthquakes, and on the relations between earthquakes and thunderstorms or the atmospheric pressure gradient. Though mainly concerned with theoretical studies, members of the Institute have also contributed to our knowledge of the vibrations of various types of buildings, of one story to eight stories in height. Many experiments have been made on artificial earthquake-waves, on the deformation of sand-masses by lateral pressure, and on seismic seawaves. The eruptions of volcanoes all over Japan have been investigated, especially those of the Komagatake in Hokkaido and of the Asama-yama in central Japan. Lastly, one of the most remarkable features of the fourteen ordinary volumes is the series of nearly one hundred mathematical memoirs, dealing as a rule with theoretical problems, but touching also on others of a more practical aspect in the vibrations of various types of buildings and the propagation of seawaves and seiches.

Obituary Notices

Sir James Currie, K.C.M.G., K.B.E.

It is with deep regret that we have to record the death of Sir James Currie. Sir James had gone to Cambridge to attend a conference on animal pathology, and was staying with Mr. Will Spens, the master of Corpus Christi College. He retired at 11 p.m. on March 16, and on the following morning was found dead in his room.

Sir James had a distinguished career of public service, and, as he would have wished, died in harness. Son of the Rev. James Currie, principal of the Church of Scotland Training College, he was educated at Fettes (where he played in the first Rugby XV and the first cricket XI), and he obtained an exhibition at the University of Edinburgh and a scholarship at Lincoln College, Oxford, in 1888. After going down, he gained teaching experience at one of the schools of the Scottish Education Board in Edinburgh, his native town. His great opportunity came in 1899 when he joined the Egyptian Education Service. He embraced it magnificently. In the following year he was appointed principal of the newly founded Gordon College in Khartoum and director of education in the Sudan.

As a start, Currie formed a school for the training of the Sudanese as teachers. Inspired by Lord Cromer, many of whose attributes he possessed, he soon won his way into the hearts of the Sudanese. He was appointed a member of the Governor-General's council, and his work in the Sudan was perhaps his greatest achievement.

Relinquishing his posts in 1914, Currie returned to England, where he went in for farming; but during the Great War, in 1916, he undertook, as director of the new Labour Supply Department, the training of munition workers, and in 1918 he joined the Ministry of Labour, again in a voluntary capacity, as controller of the training department. He originated the idea of Government instructional factories, and when he retired, early in 1921, more than 25,000 disabled ex-service men had passed through his hands.

In the same year Currie was appointed director of the Empire Cotton Corporation, and a year later a governor of the Imperial College of Tropical Agriculture, to the chairmanship of which he succeeded in 1927, after the death of Sir Arthur Shipley.

Scientific men were needed for the development of cotton-growing within the Empire, and Sir James initiated the system of scholarships for post-graduates tenable at the College in Trinidad, an example which was followed later by the Colonial Office under the Milner-Lovat Committee's scheme. Much work had to be done. As E. H. C. wrote in *The Times*: "Cotton was to be grown in a dozen different countries, each with a different climate and different conditions. There would be no uniform cotton seed which would suit each and all. First must come research in each country, experimental farms, trials of various seeds, knowledge of constituents of soils. So, just as he had first to train teachers in the Sudan before he could have schools, he must now concentrate on soil-chemists and plant-breeders before he could have seed which would not bankrupt Colonial farmers. No other man in the Empire would have seen this so clearly or have understood so well how to give practical effect to what he saw."

Sir James was also a governor of the Imperial College of Science and Technology, a member of the council of Marlborough College and chairman of the directors of Dauntsey School. To the Cotton Corporation and the Imperial College of Tropical Agriculture especially, his experience of education and research and his great powers of administration proved of inestimable value.

Sir James possessed exceptional strength of character. He had also a rich fund of humour, and this often found expression in original though apposite comments which relieved the monotony of many meetings which he attended. All who worked with him and for him, loved him and will treasure his memory.

Sir James was made C.M.G. in 1912 and a K.B.E. in 1920, and was promoted to K.C.M.G. in 1933. He was married in 1913 and is survived by his wife, Hilda Beatrice, daughter of the late Sir Thomas Hanbury of La Mortola, Italy.

Dr. Elihu Thomson

By the death of Elihu Thomson on March 13, the world has lost one of the greatest of the pioneers of the practical applications of electricity. He was born in Manchester, England, on March 29, 1853, but his father, who was a skilled mechanic, emigrated to Philadelphia, Pa., in 1858. He was educated there and attended the Central High School, a well-known technical college. His love for experimenting and invention was probably inherited from his father. At first his chief interest lay in chemistry; after he had served his time as an analyst at a factory he returned to the High School to teach chemistry and retained this post for ten years until 1880.

Prof. M. B. Snyder tells how one day in 1875 Thomson transmitted ether disturbances from the first floor of the building to the sixth floor, where his detector was a brass door knob and an ordinary lead pencil. When the apparatus on the first floor was working a stream of delicate sparks passed between the point of the pencil and the knob. This happened twelve years prior to Hertz's celebrated verification of Maxwell's theory.

In 1880, Thomson went to New Britain, Conn., as electrician for the American Electric Co., and two years later in conjunction with Edward J. Houston founded the Thomson-Houston Electric Co. at Lynn, Mass. In 1892, this company was merged with the

Edison General Electric Co. to form the General Electric Co. (America), the largest manufacturing company of electrical equipment in the world. Thomson retained his post as director of the large laboratory at Lynn, which was renamed after him, the Thomson Laboratory.

Thomson made more than seven hundred inventions, some of which have led to great developments and many theoretical discoveries. He discovered that the resistance of the electric arc varies inversely with the current. He was the first to utilize a magnetic field to move the electric arc, a method which is used in magnetic blow-out switches and electric safety valves. A notable discovery was that a copper ring placed in front of an A.C. magnet was strongly repelled, a fact which he applied to the development of repulsion motors which are much used in industry. He was the pioneer of high-frequency apparatus, making the first dynamo of this type in 1890. In 1886, he invented the art of electric welding by the resistance method. The art of welding has developed very rapidly since this date. Ships, buildings, bridges, etc., are now being welded instead of being riveted and bolted. It has also proved of great value when designing aeroplanes and large motor vehicles. His inventions show great novelty of design. The Thomson-Houston dynamo for arc lighting had a spherical armature, cup-shaped field magnets and a three-part commutator. He made most useful contributions to the field of radiology and was the first to make stereoscopic X-ray pictures.

In 1884, Dr. Thomson married Miss Mary Peck of New Britain, Conn., by whom he had four sons. Mrs. Thomson died in 1916, and seven years afterwards he married Miss Clarissa Hovey of Boston and lived at Swampscott near Lynn, where he continued his inventive work.

Elihu Thomson received many honours for his electrical and scientific work from countries all over the world. He made many friends when he was president of the International Electrical Congress at St. Louis in 1904 and of the International Electrotechnical Commission which met in Turin in 1911. The writer remembers how feelingly Elihu Thomson spoke of Prof. Silvanus Thompson when a portrait of the latter was presented in 1923 to the Institution of Electrical Engineers. He said that he felt that the late Prof. Silvanus Thompson was in many respects nearer to himself than any other man. He was successful not only in electrical work, but as an optician, a musician and an artist he had also attained distinction. He felt that in his own way he was humbly following in Thompson's footsteps.

When he was presented with the Kelvin Medal in 1924 by the leading engineering institutions in Great Britain, Elihu Thomson said that Kelvin was his ideal, as an influence and example that was not to be estimated by ordinary standards. Kelvin was lovable as a man, and unequalled as a scientific expert. Thomson regarded him as the earliest and greatest electrical engineer. In 1924, the University of Manchester, his native city, conferred on Thomson the honorary degree of doctor of science. At the festivities which took place at the World Power Conference in 1924, he and Mrs. Thomson took a leading part and were esteemed by everyone. Since then, many of us have received at Christmas time from them beautiful photographs of their garden taken in natural colours by a new method invented by Thomson. He will be missed by his many friends all over the world.

A. R.

Baron de Stael Holstein

WE regret to record the death of Baron de Stael Holstein, well known as an Oriental scholar, which is reported to have taken place recently in Peking at the age of fifty-seven years.

Baron de Stael Holstein was formerly one of the largest landowners in the Russian Baltic States; but on being dispossessed by the Revolution, he took up his residence in Peking, where he devoted himself to the study of Sanskrit and Buddhism, of which he had long been an ardent follower, adding to them Tibetan and Chinese. In so doing, he was anxious to bring about a better understanding of the Buddhist canon among the Chinese themselves, and for the furtherance of this object founded, with the co-operation of Harvard University, the Sino-Indian Institute, in which Tibetan lamas were engaged for instructional purposes, but at the same time initiated into Western methods of critical scholarship. With the assistance of American benefactions, he brought together a remarkable collection illustrating Buddhist iconography. His eminence as an Oriental scholar was recognized by the University with which his Institute was connected when he was called to Harvard for a time to occupy the chair of Sanskrit. His literary output was considerable, his work of most enduring value being the publication of a number of Buddhist texts.

Dr. F. P. F. Ransom

DR. F. P. F. RANSOM, who died on February 23 at the age of eighty-seven years, studied pharmacology as a young man in Halle and Marburg with von Behring and H. H. Meyer. They studied immunity, and the pharmacology of tetanus toxin and diphtheria toxin. They obtained evidence that these toxins passed from the periphery to the central nervous system in the trunks of nerves. Ransom also showed that the toxic effects of saponins were largely due to their affinity for cholesterol, and made an active cell-free cholera toxin.

At the age of sixty years, he was elected to a Beit fellowship, and, with Dixon in Cambridge, demonstrated the action of sympathetic and parasympathetic nerves on the bronchi. From 1912 until 1924 he held first a readership and then a chair at the London School of Medicine for Women, and published papers on the effect of caffeine on seeds, on alcohol, chloroform, pilocarpine and other subjects. His wide knowledge of pharmacology was always at the disposal of his colleagues, and he will be remembered as a kind, modest and courteous friend. He spent his last years in retirement in Somerset, and kept up his interest in pharmacology in spite of failing eyesight.

News and Views

Sir William Beveridge, K.C.B.

THE presence in Oxford of Sir William Beveridge, who will return there as master of University College next October, will greatly strengthen the young but vigorous Oxford school of philosophy, politics and economics. No head of a House there, with the exception of Mr. H. A. L. Fisher of New College, has had so brilliant a combination of an academic and public career. At Balliol, where Sir William was an undergraduate, he distinguished himself in mathematics, classics, philosophy and law. Later, he became a fellow of University College. In London he has had a wide experience as administrator, first in the Civil Service and, since the War, as director of the London School of Economics and Political Science. For many years he was at the Board of Trade and the Ministries of Munitions and Food, and there became a great and resourceful authority on problems of labour, unemployment and industrial insurance. To him more than to any other is due the organization in Great Britain of 'Labour Exchanges'. He has latterly been chairman or member of several important commissions or tribunals dealing with industrial wages and insurance. For the last eighteen years he has been a senator of the University of London and was vice-chancellor in 1926–28. He is still comparatively young. His resource and energy, and his wide knowledge of men and affairs, can now be devoted to Oxford for many years.

Social and Economic Problems for Solution

THE group of 150 distinguished public men and women of all schools of democratic public opinion who eighteen months ago published an essay in political agreement in a book called "The Next Five Years" have now submitted a narrower "Programme of Priorities" to cover a period of five years—that is, the lifetime of a Parliament ("A Programme of Priorities". Pp. 12 (Oxford: "Next Five Years Group", 1937.) 3*d*). The programme is a practical plan applicable to the political and economic situation of England to-day and is submitted for discussion by all those who see the importance of a common effort to serve the nation and strengthen its influence in the world at this critical time. A number of its proposals, such as an extended housing programme by widening the definition of overcrowding, the extension of the milk-in-schools scheme to all elementary schools, or the raising of the school leaving age to fifteen years without exemptions, merely require the tightening of legislation.

OTHER proposals which are put forward in the pamphlet give concrete expression to present tendencies in the Government or to authoritative recommendations in Commissions and reports already submitted to it. They include the provision of national parks and playing fields, recreational and cultural amenities in connexion with slum clearance and new housing estates, agricultural marketing Acts administered by appointed bodies entrusted with the duty of considering the interests of the community as a whole, the expansion of the national health insurance panel system into a public medical service, the pensioning and removal from the live register of elderly persons who have been unemployed for five years, the location of industries, measures to restore and maintain the personal qualities of the unemployed in the Special Areas, public development schemes, the co-ordination of transport, the freeing of trade by the overhaul of the tariff system, etc., the expediting of the new Factory Act, control over undesirable speculative methods of finance, further State aid for social and economic research and the encouragement of the shorter working week and annual holidays with pay. Under international relations the programme includes a proposal to all European countries to set up a fact-finding commission to examine outstanding problems such as Colonial questions, access to raw materials, the lowering of trade barriers and positive economic co-operation, currency co-ordination, racial minorities and claims to changes in territorial *status quo*, as well as renewed efforts to establish a system of collective security, the limitation, reduction and supervision of armaments and the rebuilding of the League of Nations as the main and consistent object of British policy.

The Social Credit System

UNDER the title "Poverty and Over-Taxation; the way out", the Marquis of Tavistock has published a further account of the Social Credit system (Coventry: *Prosperity* Office, 1937. 6*d*.). Among seven reasons given for the failure of the present financial system, he stresses the way in which science and machinery are destroying the need for human labour, but are increasing the output of real wealth in goods. Because the machine does the work of several hundreds of people, it becomes more and more difficult every year to find work for everyone, and no cure for poverty can be found by attempting to give everyone a paid job in industry. The effect of machinery and fresh scientific inventions is to destroy the demand for human labour, and although new industries are started, fewer and fewer people are needed. Apart accordingly from the necessity of education for leisure, it is urged that the State should direct the banking system to create and issue, *not* in the form of debt, as much money as is required to enable the citizens of the country to buy at a price fair to sellers all that they desire of what industry and commerce can produce or import. Of the three main items in the reform necessary to make money the servant of industry, aiding the consumption and production of goods, the first is the abolition of the Gold Standard and of any gold basis for the issue of money, since it is goods and not gold which give value to our money. It is suggested that under a policy of National Dividends, a man unable to find work would still be able to live in reasonable comfort without being a burden on others and he would be able to help the man at work by being in a position to buy his goods. It would still pay a man to get work if he could, as wages would be paid extra to National Dividends and a natural check to living on National Dividends would operate because their amount depends on the country's production of goods.

Japanese Institute for Science of Labour

In view of the importance which labour is commonly regarded as possessing in Japanese competition, the annual report of the Institute for Science of Labour, which was transferred from Kurasiki to Tokyo at the end of 1936, is of considerable interest. The report indicates that much of the work of the Institute follows the lines of work of the National Institute of Industrial Psychology in Great Britain. Among a number of completed researches mentioned in the report are those on the clothing of farmers, syphilis morbidity in villages, psychological qualifications for textile workers, an examination of vocational testing methods, studies on manual dexterity and on the physical fitness of employees, studies on motions and positions in working, on repetition work, psychological differences between skilled and unskilled workers in a weaving factory. Some of the physiological work is on lines similar to that pursued by the Industrial Health Research Board in Great Britain as, for example, the investigations on environmental conditions, such as climate, the effect of occupational activities on basal metabolism, the metabolism of heavy muscular labour or the physiological studies on walking, but in addition the Institute has completed a preliminary research on the daily protein requirements of the nation. Occupational diseases and the prevention of accidents have also received attention, and it is interesting to note from abstracts of publications of the Institute included in the report that scientific workers in Japan are now advocating on scientific grounds raising the minimum age of juvenile labour to at least fourteen years, with special protection up to eighteen years of age.

National Research Laboratories, Ottowa

The National Research Laboratories at Ottawa now employ about 190 workers organized in five divisions: agriculture and biology; chemistry; physics and electrical engineering, mechanical engineering including aeronautics; and research information, with which is associated a national scientific library service. A review of the year's work recently issued for the National Research Council of Canada stresses the increasing service which is rendered to industry; much of the work carried out in the Division of Biology and Agriculture forms part of large co-operative research projects, mainly in collaboration with the Department of Agriculture but also with the universities and similar organizations. A low-temperature laboratory has been equipped, and physical conditions for dechilling boxed poultry without condensation have been established. Research on malting barley is being carried on in co-operation with industry, and a comprehensive review of the literature on chemical weed killers is being published as a guide to research in this field.

The Division of Chemistry is in organized relations with the laundering and dry-cleaning industry, the asbestos industry, the manufacture of basic refractories, and to a slight extent the woollen and sugar industries. In an investigation on the chemical principles in certain groups of wild plants native to Canada, a method of synthesizing certain plant hormones which stimulate plant growth, including root formation on cuttings, in a remarkable way, was discovered. An extremely efficient distillation column was built in the laboratories during the year and its application in the oil-refining and synthetic chemical industries, the coal tar industry, etc., is being investigated. The snow resistance of aircraft skis has been thoroughly investigated by the Division of Mechanical Engineering, as well as the stalling of heavily tapered wings on modern aircraft. A new heating system for refrigerating cars has been developed, as well as a new machine for converting aerial photographed information into a map. Radio methods in weather forecasting are being investigated, the Physics and Engineering Division is also giving a considerable amount of attention to the development of new or improved methods or instruments for measuring sound absorption, gauges, voltage in X-ray work, grading of colours for fastness, etc.

Educational Research in the United States

Educational research in the United States proceeds on a scale never hitherto approached in that or any country. Some idea of the volume of work in this field may be gathered from a "Bibliography of Research Studies in Education, 1934–35", issued from the United States Office of Education (Washington: Govt. Printing Office. 25 cents). Herein are listed 2,971 studies reported by 145 institutions, including 384 doctors' dissertations, 2,368 masters' theses and 219 studies reported as faculty research. An introductory note mentions the following as "especially timely topics" of some of the theses; apprentice training, business depression, correlation of school subjects, crime prevention, exploratory courses, leisure-time activities, open forums, orientation courses, teachers' strikes, rehabilitation of the disabled, traffic schools, new systems in several foreign countries. Another favourite subject for educational research in America is the technique of reading. Fifty-two of the studies listed deal with investigations such as the measurement and improvement of silent reading among college freshmen. It seems to be not unusual for a reading test to form part of the college entrance examination, and it has been found that many students are seriously handicapped in their work by remediable faults in their modes of reading. Within a day or two of the publication of this bibliography appeared No. 1 of vol. 24 of the University of Colorado Studies containing abstracts of 136 theses for higher degrees. An analysis of the subject headings of the theses affords further evidence of what might almost be called the rage for educational research prevalent in some American universities, for no fewer than 47 of the theses are devoted to research in this field.

Records of Bushman Art

THE Department of the Interior of the Union of South Africa and the Commission for the Preservation of the Natural and Historical Monuments, Relics and Antiquities of South Africa have issued an official circular inviting the co-operation and assistance of members of the public in recording and preserving examples of Bushman rock-painting and drawing. In asking observers to forward such records to Prof. C. van Riet Lowe, as director of the Bureau of Archæology at Johannesburg, the circular points out that although the existence of a large number of such examples of Bushman art is already known, it is certain that the list is by no means complete, while time, exposure to weather, as well as acts of vandalism are obliterating many of them year by year. In order that the records may be as complete as possible, the circular enumerates the data which are essential for the purpose of accurate record, as well as for archæological study, and gives instructions on the best methods of taking photographs and squeezes in varying conditions. The circular, as received, is accompanied by an excellent and extremely instructive map, showing the distribution of the known sites on which examples of the paintings and engravings have been recorded, as well as sites which have been proclaimed for preservation by the Commission for the Preservation of Natural and Historic Monuments.

Fire Precautions in Electrical Stations

SERIOUS fires from electrical plant in power stations are fortunately rare in Great Britain, but during the last few years there have been several disastrous fires both at home and abroad, and so the paper on fire precautions by F. C. Winfield read to the Institution of Electrical Engineers on February 11 is a useful one. In electrical supply it is recognized that the maintenance of this supply is the outstanding requirement. This is usually done by duplicating all the principal cables supplying the current, and also some of the plant. Since all electrical plant is subject to the two risks of fire and explosion, this provision does not secure the desired maintenance of the supply unless measures are taken to ensure that such duplicates cannot be simultaneously impaired. It is necessary therefore to provide physical separation of electrical duplicates by dividing them up in separate buildings or enclosures. Brick walls and reinforced concrete construction have excellent fire-resisting properties. Pitched roofs supported by steel trusses should be protected by a fire-resisting inner ceiling. All windows should be of wired glass and all internal doors of fireproof self-closing design. The development of the oil-less circuit and breaker on the Continent is a step in the right direction. An important factor in fighting an oil fire is the dense black smoke, which impedes or prohibits access to the seat of the fire. This is a very serious consideration in dealing with fires which occur in the inner regions of large power stations. For this reason it is recommended that all large transformers or heavy switch-gear should be mounted in separate buildings or in chambers opening to the outer air and sealed off from the inner side. Unfortunately, no practical method of routine testing has yet been devised by means of which the failures that produce fires can be anticipated.

Underwater Power and Telephone Cables

IN the course of developing underground cable networks, the engineer has sometimes to negotiate waterways and harbours. For large waterways three methods are used. The first is to make a special cable tunnel. But the expense of construction is heavy, and is only justified when a large block of main cables has to be taken across. Examples of this type are the crossings under the Thames at Barking, Deptford and Battersea and underneath the Tyne at Newcastle. The second method is to dredge a trench in the river bed in which the cables are laid directly, and the third method is to lay them in the bed of the waterway without recourse to dredging. The second method is, when practicable, preferable to the third method, especially in navigable waterways, where the ships' anchors damage them. In certain cases, owing to the width of the waterway or because the nature of its bed renders dredging impracticable, the third method is employed. In the Engineering Supplement to the *Siemens Magazine* of March, it is pointed out that when this is done in running or tidal waters, a new problem arises. No matter how carefully the cable is laid, it may at any time, due to the shifting of the bottom, be left suspended between two points. In this condition, it is subject to high-frequency vibrations set up by the current. These vibrations are very harmful to the lead as they rapidly produce inter-crystalline fracture and failure due to ingress of water. Messrs. Siemens have successfully combated this trouble by a special type of cable. A rubber hose protection is applied between the lead sheathing and the armouring. This damps out harmful frequency vibrations before they reach the lead.

Progress in Marine Radio Communication

THE first practical application of radio provided communication with ships at sea over distances and under conditions which made all other forms of communication impossible. More than thirty-five years have elapsed since that first application, and marine radio still remains unique for this particular purpose, so important to commerce and so essential to safety. In no other field, except that of air transport, is radio irreplaceable by other forms of communication. A general survey of the present state of the art of marine radio communication was given at a meeting of the Wireless Section of the Institution of Electrical Engineers on March 3, when Commander F. G. Loring and Messrs. W. L. McPherson and W. H. McAllister presented a paper entitled "A Survey of Marine Radio Progress, with Special Reference to R.M.S. *Queen Mary*". The first section of the paper comprised a short summary of progress during the last five years, with particular reference to the nature and volume of traffic, the types of communication involved, and the increasing use of direction-finding equipment by navigators. Next the types of equipment fitted in cargo vessels and the smaller class of passenger vessels were described. An account was then given of the radio problems encountered in the 'express steamer' class of vessel, and the paper concluded with a detailed description of the radio station of R.M.S. *Queen Mary*, the latest representative of its class. This installation comprises four transmitters and nine or ten receivers ; the control room can handle four independent duplex circuits, and provision is made for high-speed transmission and reception, and simultaneous communication on both telegraphy and telephony with both sides of the Atlantic. The results of the experience obtained with this equipment have shown that in spite of the difficulties peculiar to ship installations of this character, by careful engineering, a good approach can be made to the operating efficiency of a large land station.

Use of Diesel Locomotives in Mines

IN coal and metalliferous mines, as the working faces advance from the shafts, there is a desire to transport workmen to within easy reach of their working places and there is a large field of usefulness open to safe and convenient locomotives suitable for this purpose. Electric trolley, compressed air, storage battery, benzol and Diesel locomotives have been used, and it is interesting to note that tests have been carried out by the Ruhr Testing Station officials which show that Diesel locomotives are safe for use in mines. An investigation has been carried out by Messrs. George S. Rice and F. E. Harris of the United States Bureau of Mines, and a report has been published under the title of "Diesel Mine Locomotives—Development and Use in European Coal Mines" (a Publication of the Department of the Interior, United States Bureau of Mines, November, 1936). It is stated in this report that provided a reasonable amount of air is circulated along the roadways where these Diesel locomotives are in use, dangerous percentages of carbon monoxide do not occur if the machines are maintained in a good working order. These locomotives are being used in American mines, and they are being substituted for benzol locomotives in mines in Germany, Belgium and France. At a colliery in Scotland, a Diesel locomotive has been on trial since 1935. Another large colliery company in Yorkshire is contemplating using Diesel locomotives for carrying men from the pit bottom to points near the face, and the necessary investigations are at present being made. In Great Britain special permission is required to introduce internal combustion engines into mines by Section 58 of the Coal Mines Act, 1911, which prohibits the use of these engines in underground workings without permission.

Air Survey

THE Air Survey Committee grew from a suggestion of the Army Council in 1919, and now includes representatives of the War Office, Air Ministry, Admiralty, Ordnance Survey and Department of Scientific and Industrial Research. The Committee's second report (Report of the Air Survey Committee No. 2. H.M. Stationery Office. 4*s*. net) reviews at length the methods of air survey and the apparatus at present available. A useful appendix analyses the cost of air survey. Conditions, of course, vary, and the estimate is based on the existence of an air survey organization on a permanent basis undertaking operations on a large scale. It is assumed that the area is undeveloped and consequently difficult for land transport. Under these conditions the cost of the survey is estimated for an area of one million square miles which would entail six years work for completion of the air photography. For this, five aircraft in action and one in reserve would be required. This fleet could do 2,000 hours of photographic flying each year. The total cost, which of course includes the cost of photographic material, works out at twenty-three shillings per square mile, but considerably more if a smaller area is surveyed, rising to 180 shillings per square mile for an area of 500 square miles. These must be taken as average figures, and the cost would be much higher in urbanized areas. The production of the maps is additional to these costs.

Works of Charles Darwin in Russian

THE fiftieth anniversary in 1932 of Charles Darwin's death was marked with perhaps greater solemnity in the U.S.S.R. than elsewhere, since both Engels and Lenin adopted and popularized Darwin's evolutionary idea. Until that time, only more or less abbreviated translations of Darwin's works had been available to Russian readers, and most of them were out of print. It was therefore decided that a new translation should be published, which had to be the most complete of all editions of Darwin's works existing in any language. The preface to the first volume, published in 1935 by the State Publishing House for Biological and Medical Literature, Moscow and Leningrad, points out the necessity for such an edition, particularly at the present time when "the economic crisis and the political and spiritual reactions caused by it, not only call for a complete oblivion of Darwin, but when the bourgeoisie, in its futile struggle against darwinism, more and more often invokes the darwinism's decrepit antithesis—religious teachings on the creation of the world".

ACCORDING to the plan, the edition will comprise twelve volumes, and will include the translations of all books, and all papers by Darwin, except some highly technical ones from which only excerpts will be published. Every separate work will be supplied with an introduction by an expert in the particular problem, who is in many cases responsible for the actual translation, or for editing it, as well as for commentaries that serve to explain various points, to bring up to date the nomenclature of plants and animals, etc. The first volume that appeared in 1935 contains the "Journal of Researches, etc." supplemented by the "Diary" (as published by Norah Barlow); the second, printed in 1936, includes a series of zoological works, the book on earthworms, and a series of geological works, especially that on the formation of coral reefs. The editorial work is done very thoroughly, but the appearance of the book leaves much to be desired, as the paper (particularly in the first volume) is of indifferent quality, affecting the illustrations, which are reproduced mostly from original English editions. When (and if) all the promised twelve volumes are published, it will be possible to judge the whole enterprise in greater detail.

Recent Acquisitions at the Geological Museum

THE Geological Museum has recently put on exhibition two new dioramas illustrating the occurrence and exploitation of gold ore at the Lake Shore mine in the Timiskaming District of Ontario. This mine is the largest gold producer on the American continent, and one of the most important in the world. One of these dioramas introduces a new technique, in illustrating the geological structure to a depth of 4,500 feet, as well as the general surface topographic features. The dioramas have been presented by Mr. Harry Oakes, who originally staked the property. Among other recent additions to the collections are a jade hei-tiki, carved by the Maoris, the gift of H.M. Queen Mary; a very extensive collection of polished Italian marbles, presented by Mr. Percy C. Webb; and a magnificent group of deeply coloured amethyst crystals from Brazil, loaned by the managers of the Royal Institution. The Geological Society of London has presented a group of large pillars of basalt, from the Giant's Causeway in Antrim; an *Ichthyosaurus* from the Lower Lias of Barrow-on-Soar; a very fine slab of Wenlock Limestone with *Periechocrinus moniliformis*, etc., collected by the late Earl of Dudley; and a beautiful specimen of *Pentacrinus briareus* Miller from the Lias of Lyme Regis, collected by Sir H. T. de la Beche, the first director of H.M. Geological Survey. Within recent months, the Museum has added to its permanent exhibits on economic geology displays on abrasives, moulding sands, refractory materials, and other subjects of industrial interest.

Codes Used in Weather Forecasts

"WIRELESS WEATHER MESSAGES, 1937" (Publication M.O. 252, tenth edition. London: H.M. Stationery Office. 1*s*. 6*d*. net) has the sub-title "Particulars of Meteorological Reports issued by wireless telegraphy and wireless telephony in Great Britain, Gibraltar, Malta, Middle East and Iraq", and this defines its scope. It incorporates changes in some of the specifications of the International Code used for meteorological messages that were adopted at the International Meteorological Conference held at Warsaw in September 1935, changes which came into operation on January 1, 1937. There are two sections giving, respectively, details of the codes used for weather forecasts for aviators and details of the codes used for messages giving special information supplementary to routine reports for aviation. These sections follow the main body of the publication dealing with the main transmissions from shore stations and ships. In spite of some economy of space that has been introduced in setting out the details of individual transmissions, this publication now contains about ninety pages, and its growth in recent years corresponds with that of aviation and of the international exchange of meteorological information.

Carnegie Trust for the Scottish Universities

THE Carnegie Trust for the Universities of Scotland has recently published its report for 1935–36. Grants to universities and extra-mural institutions amounted to £51,460, expenditure on assistance in payment of class-fees to £53,971, grants under the Trust's scheme for endowment of research to £17,880. The progress of recovery from economic and industrial depression in Scotland is reflected in the exceptional number of resignations of fellows and scholars due to their appointment to paid positions. Of thirty-two fellows and scholars in chemistry, organic and physical, fifteen resigned, some almost at the commencement of their appointment periods. Another indication of prosperity is the sharp rise in the amount of voluntary repayments by former recipients of aid from the Trust. These repayments amounted to £2,362, the largest amount so received by the Trust since 1928–29, and only exceeded in that year and 1926–27. The aggregate amount of such repayments since the inauguration of the scheme in 1901 is £38,000.

Rearing Marine Organisms in the Laboratory

THE *Aquarist and Pond-Keeper* of January–February 1937, besides a number of other interesting papers, contains an article by Mr. Douglas P. Wilson, naturalist at the Marine Biological Laboratory, Plymouth, on the plunger jar for rearing marine organisms. This is a piece of apparatus much used in the Plymouth Laboratory, originally planned and used by Mr. E. T. Browne for rearing medusæ, the main idea being to create a definite rhythmical movement in the aquarium by means of a glass plate, the plunger, manipulated by a siphon. All workers at Plymouth are familiar with the plunger jar, and it is now used in many laboratories. Numerous well-known researches have been successfully conducted by its aid; echinoderms, molluscs, crustaceans, worms, have all been reared, and it is fit that the plunger-jar should be introduced to all those who wish to keep marine animals. Mr. Wilson, who has himself reared successfully several sea-worms from the egg, describes how this can be done.

Annual of the Astronomical Observatory, Madrid

THE receipt of the usual annual astronomical handbook from Madrid ("Anuario del Observatorio Astronómico de Madrid") in the unusual circumstances that exist to-day in Spain, calls for at least a brief comment. The 1937 handbook contains current tabular matter that is likely to be of general use to observers in Spain—astronomical elements, tables of sunrise and sunset and of moonrise and moonset (in each case for Madrid), planetary phenomena, solar and lunar eclipses, positions of the principal nebulæ and double stars, etc. A set of monthly charts is included to illustrate the night-skies as seen by an observer at Madrid, and a concluding chapter describes the use of wireless time-signals for the dissemination of standard time and the application of the signals to longitude determinations.

Société Astronomique de France (1887-1937)

THIS year, the Société Astronomique de France celebrates its fiftieth anniversary, and the January issue of *L'Astronomie* recounts the circumstances of its inception on January 28, 1887, owing chiefly to the efforts of M. Camille Flammarion. The aim of the new society was to foster in France an interest in astronomy and to establish a link mainly between non-professional astronomers in all parts of the country. The society now has a membership of 5,000, and includes astronomers from many countries; it possesses an observatory in Paris which members may use, and records its regular meetings and general activities as well as publishing papers in its monthly periodical, *L'Astronomie*. We welcome this opportunity of extending our congratulations.

The Pasteur Institute of Southern India

MAJOR IYENGAR, director of the Pasteur Institute of Southern India, Coonoor, has issued his annual report for the year ended March 31, 1936. The number of patients who underwent a full course of treatment at the Institute was 433, and 102 patients received incomplete treatment for various reasons. There were no deaths from hydrophobia among those treated at the Institute. In addition, more than 14,000 courses of antirabic vaccine were issued to outlying centres. Details of the course of treatment are given; Semple's carbolized 5 per cent sheep vaccine was in use throughout the year, prepared from Paris fixed virus.

Announcements

PROF. HEINRICH WIELAND, professor of chemistry at Munich, has been elected a corresponding member of the Physico-Mathematical Section of the Prussian Academy of Science.

SIR HARRY LINDSAY, director of the Imperial Institute, has been nominated as president of the Association of Special Libraries and Information Bureaux, (ASLIB), for the year 1937–38. The Association will hold its fourteenth Annual Conference at Gonville and Caius College, Cambridge, during the week-end beginning September 24. Particulars may be obtained from the Secretary of the Association, 31 Museum Street, London, W.C.1.

MR. T. G. ROSE has been appointed general director of the National Institute of Industrial Psychology, to collaborate with Dr. C. S. Myers, the principal, who will retain the position held by him since the inception of the Institute sixteen years ago.

LORD SNELL will open the Studio of Animal Art in the Zoological Gardens of the Zoological Society of London, Regent's Park, N.W.8, on April 21 at 2.30.

A BUST of Prof. Babes, founder of the first Pasteur Institute in Bucharest, who died ten years ago, was recently unveiled in Bucharest, when memorial addresses were delivered by Profs. Bacalogliu, Ciuca, Manicatide, Marinesco and Proca.

THE thirty-ninth annual conference of the Institute of Public Cleansing will be held at Margate from June 14–18. Further information can be obtained from the honorary secretary of the Institute, 160 Buckingham Palace Road, S.W.1.

AN International Conference on "Esperanto in Modern Life" will be held in Paris on May 14–17. Participation in the Conference is free. Further information can be obtained from the secretariat, Conférence Internationale (L'Esperanto dans la Vie Moderne), 34 Rue de Chabrol, Paris, 10^e.

THE thirty-fifth annual session of the South African Association for the Advancement of Science will be held at Windhoek, South-West Africa, under the presidency of Lieut.-Colonel C. Graham Botha, on July 5–10. Further information can be obtained from Dr. C. F. Juritz, Department of Agriculture, P.O. Box 3, Capetown.

A COMMITTEE has been formed by the French Air Ministry to deal with the requirements of the air force and to secure the best possible adaptation of the human organism for military aerial navigation. The functions of the committee will be first to express opinions on biological and medical problems brought before it by the Air Minister, and secondly to supply the Minister with useful suggestions regarding biological questions relating to military aviation.

THE triennial award of the Coopers Hill War Memorial Prize and Medal will be made this year by the Institution of Electrical Engineers, which invites members to submit for consideration a paper on any subject coming within the scope of electrical science or electrical engineering and their applications. Further information can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2.

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 634.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Effects of Traces of Metallic Ions on Monolayers

IN a recent communication to NATURE[1], Prof. W. D. Harkins and Dr. R. J. Myers have directed attention to the effects of minute traces of metallic ions on the behaviour of monomolecular films at the surface of aqueous solutions.

It may be of interest to investigators in these fields to add that the effects of such traces of impurities are not always confined to modifying, to a greater or less extent, the physical characteristics of the films, but may on occasion play a predominating part in chemical reactions taking place in the films. While treating with reserve all results on unbuffered aqueous solutions, since marked changes in the characteristics and reactivities of films of various types can be effected by small changes in the pH of the underlying solutions, profound effects on the reactivity of molecules in the boundary state can on occasion be observed due to the presence of even slight traces of metallic ions, especially nickel or copper.

The importance of minute traces of metallic ions is clearly demonstrated in the examination of photochemical reactions in monolayers[2,3,4]. In the case of the photochemical hydrolysis of monolayers of stearic anilide on $5N$ sulphuric acid substrates, it has been found that the velocity of an anomalous 'fast' reaction was reduced to a normal value by the addition to the substrate of potassium cyanide in a concentration of the order of $M/2000$. In the photochemical decomposition of monolayers of α-hydroxystearic acid on $N/100$ sulphuric acid substrates, probably with splitting off of carbon dioxide, the unsensitized process appears to occur only with radiation of wave-lengths shorter than 2400 A., but sensitization to the wave-length 2537 A., isolated by means of a monochromator, can be produced by the presence of sub-analytical quantities of nickel ions; for example, 3γ of nickel in 500 c.c. of substrate for a film of area 100 sq. cm. Evidence was obtained that sensitization occurred only after the formation of a complex which appears to consist of one molecule of α-hydroxystearic acid and one nickel atom. Further, it is probable that the photochemical oxidative and hydrolytic changes in monolayers of proteins, such as ovalbumin, can be sensitized to wave-lengths greater than 3350 A. by traces of nickel and copper, although the possibility of unsensitized processes at these long wave-lengths cannot be entirely excluded.

On occasions the source of copper contamination has been traced to the distilled water, and in this it can be estimated by its catalytic activity on alkaline sulphite oxidation.

The effects due to the adventitious presence of traces of the alkaline earths are much less marked when the films are on acid substrates, as Langmuir has pointed out. However, some years ago, Dr. A. H. Hughes, working in this Laboratory, found that ferric ions even in $N/100$ hydrochloric acid, would affect films of myristic acid both with respect to the state and phase boundary potential of the film; ferrous ions, on the other hand, in the same substrate at concentrations of 1·2 gm. ferrous sulphate ($FeSO_4.7H_2O$) per litre had no appreciable effect until oxidized by hydrogen peroxide. The ionic concentrations in these cases were of a different order of magnitude from those which we have considered above.

Similarly, in the case of stearic acid monolayers on $N/100$ hydrochloric acid, an increase of phase boundary potential of 55–60 millivolts is produced by the presence in the substrate of ferric ions in concentrations greater than $M/5000$. No changes were observed with copper, nickel, cobalt, chromic or ferrous ions, even in concentration of $M/300$ in the substrate. Monolayers of α-bromostearic acid on $N/100$ hydrochloric acid show an increase of phase boundary potential, and solidification, on addition to the substrate of ferrous ions in a concentration of $M/1000$, but only in the presence of hydrogen peroxide; $M/10,000$ solutions of lead acetate lower the phase boundary potentials of films of α-bromostearic acid by 30 millivolts.

In contrast to the case of stearic acid, films of α-bromostearic acid at pH 2 and pH 6 show no changes on addition of ferric ions to the substrate. While nickel and chromic ions produce an increase of phase boundary potential of films of α-hydroxystearic acid at pH 2, no changes are observed with these ions in the case of stearic acid and α-bromostearic acid. At pH 6, monolayers of ovalbumin show an increase of phase boundary potential on addition to the substrate of copper ions in concentration $M/3000$; nickel, ferric and uranyl salts are without effect even at much higher concentrations.

Since the chemical reactivities of the substances forming the films, as well as the physical characteristics of the films themselves, are so greatly affected by these metallic impurities, we have for the last few years made a practice of attempting to eliminate them by using glass or quartz troughs, employing a mica boom for the Langmuir balance and paying especial attention to the distilled water and the purity of the buffer salts. We may mention that we have not been uniformly successful in eliminating, on every occasion, all traces of metals which act as catalytic or photosensitizing agents, and believe that our experiments are especially affected by copper in so far as the activity is destroyed by the addition of potassium cyanide.

The profound modification of the chemical properties of the monolayers of widely different compounds produced by the presence of extremely small traces of active substances including metallic ions is probably of great biological significance. The phenomena described are characterized by a sensitivity and specificity which is remarkably similar to that of many pharmacological actions. We wish to suggest that these methods may offer a means of approach, not only to the problem of the oligodynamic action of metals, but also to the elucidation of more general aspects of the action of drugs and the mechanism of photo-biological sensitization.

In a recent issue of Nature, Myers and Harkins[1] directed attention to the possibility of considerable errors arising in experiments on monomolecular films where small quantities of ions are introduced from the glass vessel or the metal trough. Experiments which we have carried out recently at University College, London[2], show that corresponding errors may arise in the measurement of interfacial tensions as a result of the presence of minute quantities of ions in the distilled water. Thus when using ordinary laboratory distilled water, minima were obtained in the interfacial tension-concentration curves for sodium cetyl sulphate against various oils, the interfacial tension with 0·05 per cent sodium cetyl sulphate being several hundred per cent higher than the minimum which occurred at about 0·015 per cent. Similar results were obtained with sodium salts of other long-chain acids. On using very good conductivity water (specific conductivity $0{\cdot}1 \times 10^{-6}$ ohm.$^{-1}$ cm.$^{-1}$ or less) these minima were no longer found. The ordinary distilled water evidently contained small quantities of a cation which strongly depresses the interfacial tension of such systems, its effect being greater in the lower concentrations of long-chain salt.

The effect of salts in lowering the interfacial tension of oil against solutions of the salts of long-chain acids seems to depend primarily on the valency of the cation. Thus in a particular case (with 0·005 per cent $C_{17}H_{33}CON(CH_3)CH_2CH_2SO_3Na$) the concentration of salt required to diminish the interfacial tension from 6·25 to 1·0 dynes/cm. was 0·32 *N* sodium chloride, 0·003 *N* calcium chloride and 0·00005 *N* lanthanum chloride. The effect is independent of the nature of the anion, and is therefore analogous to the Schulze-Hardy rule for the precipitation of colloids. The influence of calcium salts has previously been observed by Harkins and Zollman with sodium palmitate[3]. In our experiments we have the same influence even when a long-chain acid with a soluble calcium salt is used.

On increasing the concentration of the salt the interfacial tension at first drops and then reaches a value which shows no further decrease. The higher the valency of the salt, the lower are these final values.

It would seem that the influence of the cation is in reducing the repulsion between the heads of the long-chain ions adsorbed at the interface, so allowing a closer packing in the interfacial film, with a consequent further lowering of the interfacial tension.

If our theory is correct, that the effect is primarily dependent on the valency of the ion with charge opposite to that of the long-chain ion, a corresponding effect, dependent on the valency of the *anion*, would be expected with such substances as cetyl pyridinium chloride adsorbed at the interface. Unfortunately, it was necessary to discontinue the research before this could be investigated.

Acute Mercury Poisoning in a Respiration Chamber

In the Laboratory of Zoophysiology we have a steel chamber of 27 cubic metres capacity, which is generally ventilated at a rate of 20 cub.m. per minute at pressures from the atmospheric down to 200 mm., corresponding to a height of 10 km.

In certain experiments it is used, however, without ventilation as a closed chamber in which the air is simply circulated, the oxygen supply being sufficient for two persons over twenty-four hours or more. In one such experiment, the effect of 4·5 per cent carbon dioxide had been studied over 19 hours without any symptoms beyond a pronounced hyperpnœa, but when it was desired to repeat this experiment and extend it over several days, the subjects became ill with bronchial irritation, violent coughing and severe headache after a few hours and had to break off.

In the night a few hours later, the condition became worse, with increased temperature, dyspnœa and nausea. After three days, a stomatites affection supervened lasting two weeks, and the dyspnœa and fatigue by muscular exertion lasted for months.

Experimental animals (guinea pigs, rats and mice) were killed by the air in the chamber in 24–48 hours with severe pulmonary œdema.

A careful analysis showed that the symptoms were due to mercury poisoning from droplets spilled on the floor. Pulmonary symptoms became pronounced only when hyperpnœa was produced (by carbon dioxide), but in the absence of this the animals developed œdema and hæmorrhagia of the lower gut and died in three to four days instead of one to two days. When the air in the chamber was not artificially mixed, the animals would remain alive for several days more. Even when the chamber had been cleaned out and every visible trace of mercury removed, symptoms of mercury poisoning could still be produced in one to two weeks, and the last invisible traces had to be removed by long-continued ventilation.

It is evident that mercury in a non-ventilated or poorly ventilated room can become very dangerous, especially at high temperature, when the air is kept well mixed and when the subjects are breathing deeply, as with muscular work. It would appear that even in ordinary rooms in which mercury is spilled occasionally and can become finely divided and distributed by floor scrubbing, the air can become sufficiently poisonous to cause mild chronic symptoms in persons spending much of their time in such rooms, and this note is published mainly to warn against such danger.

A full account of the experiments will be published in *Skand. Arch. Physiol.*

Ammonia Formation in Shed Blood and a Characteristic Deaminase of the Blood Stream

APPLYING a method[1] for determining the blood ammonia by which forty determinations may be easily carried out in a few hours on 1 ml. samples, certain curious facts have been discovered. As is well known, ammonia forms in shed and sterile blood, and it has been shown to begin from zero concentration[1]. In a further study here, it has been observed that the formation goes in a succession of well-marked stages. Five such have been observed over the 24 hours. Such phasic formation has been observed for the rabbit, man and bird, appearing in the blood from each individual but at somewhat varying times, so that averaging the results from many animals will smooth out the curve of formation.

The following gives a summary of the phases as they appear in oxalated and sterile rabbit's blood (whole or laked) at room temperature.

	Duration (min.)	Conc. reached (γN%)
1st phase	0–5	50
2nd phase	5–45	200
3rd phase	45–100	400
4th phase	100–200	700
5th phase	240–400	1600

These figures are only very approximate, since occasional delays of upwards of an hour or more may occur before the appearance of a phase, the blood ammonia remaining constant the while. The optimum *p*H for the formation is about 8·7, though at 9·1 it is only a little less. The formation is also much influenced by saline concentration and practically ceases with 5 per cent sodium chloride. A reversal effect has been observed on the acid side and is being investigated.

During a study of the effect of adding a large number of different amino compounds to shed blood, a very potent deaminase of adenosine has been discovered therein. This would seem universally distributed, if we may judge from its appearance in the blood of man, fowl, frog and the lug worm (*Arenicola*). Its concentration in rabbit's blood is such that small quantities of adenosine added to shed blood (laked) are deaminated to within 60–90 per cent of the maximum in five minutes, the blood being maintained at *p*H 6·7 (most suitably by such a buffer as maleic acid owing to the specific action of the phosphate). This deamination rate occurs at room temperature and with a blood dilution of 1 : 3. The blood concentration of the enzyme is sufficiently high in the rabbit to suppose that all the adenosine deaminase previously found in muscle and liver[2,3,4] may have been really contained in the residual blood in these tissues.

By comparison with adenosine, adenylic acid (from muscle) added to laked blood is practically untouched after several hours, unless buffered towards the acid side (maleic acid buffers) and even then very much more slowly than adenosine. In fact, just as the adenylic acid deaminase may be described as the special deaminating ferment of muscle, so adenosine deaminase may be regarded as characteristic and apparently universal for the blood stream, and appears both in plasma and in red corpuscle.

It has also been shown here that the nucleated corpuscle of the fowl can deaminate adenine, guanine and cytosine readily at room temperature.

A Simple Aromatic Œstrogenic Agent with an Activity of the Same Order as that of Œstrone

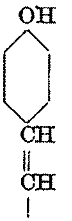
IT has previously been shown that the phenanthrene nucleus is not an essential part in the molecule of an œstrogenic substance[1], since the full œstrus response could be produced by the injection of substances so simple as 4 : 4′-dihydroxy diphenyl. Further experiments with compounds of this type have been made, and the following table indicates the potency of some new substances.

TABLE 1.

Substance	Dose in mgm.	Percentage positive
4 · 4′-Dihydroxy dibenzyl ..	100	100
4 : 4′-Dihydroxy stilbene .	10	100
,, ,, ,, . .	5	60
4-Hydroxy stilbene	10	100
,, ,, ...	5	40
Stilbene	25	100
4 . 4′-Dihydroxytolane ..	10	100
,, ,, .	5	80
4-4′-Dihydroxy diphenyl ether .	100	100
4-Hydroxy-phenyl cyclohexane ..	100	80

In view of the activity of stilbene, it was decided to experiment with substances containing only one benzene ring, and it was found that so simple a compound as *p*-hydroxy phenyl ethyl alcohol was capable of producing a full œstrus response in 60 per cent of animals when injected in doses of 100 mgm.

A much more potent substance, however, was found to be the phenol derived from the essential oil anethole. This substance, namely, *p*-hydroxy propenyl benzene, or anol, was found to possess a very high degree of activity.



In each case the material was administered dissolved in 3 c.c. of sesame oil, and was given in six injections, morning and evening during three days. The rats were smeared on the morning of each day, and on the fourth and subsequent days were smeared at midday and in the evening in addition. *p*-Hydroxy propenyl benzene when administered in this manner was found to be active in doses from 100 mgm. down to 0·001 mgm. Thus 1 γ is capable of producing a full œstrus response in 100 per cent of the animals injected. The amount of œstrone required to produce a similar response in these animals is in the region of 1·γ. It can be seen, therefore, that this simple substance has an activity approaching that of the naturally occurring hormone, œstrone. It is also interesting to note that the benzoylated compound is active. (The benzoate of *p*-hydroxy propenyl benzene crystallizes from alcohol in plates, m.p. 124° C. and gave on analysis C = 80·4 per cent, H = 6·0 per cent; $C_{16}H_{14}O_2$ requires C = 80·6 per cent, H = 5·9 per cent.)

It is as yet too early to discuss the theoretical importance or therapeutic application of these observations, but the fact that the potency is so high brings a new importance to the investigation of synthetic œstrogenic agents.

Cyclical Fluctuations in Œstrin Threshold

Cyclical changes in the accessory reproductive organs of female mammals have been ascribed entirely to cyclical fluctuations in the secretion and interaction of the ovarian hormones. Fluctuations in the latter are controlled by the anterior lobe of the pituitary.

Experiments in which œstrogenic hormone has been injected into the same female rhesus monkeys over a period of two years show that a new factor must be taken into account in the explanation of rhythmical changes in the accessory organs. It appears that the threshold of a monkey to œstrogenic stimulation varies cyclically. The least constant daily dose of œstrogenic hormone that is required to influence the uterus sufficiently for the cessation of injections to be followed by a phase of uterine bleeding, or that is necessary to maintain the uterus in a phase of growth, is not necessarily the same on different occasions. In one experiment, phases of uterine bleeding occurred at regular intervals of from five to seven weeks in a spayed immature monkey that was injected daily with 100 I.U. of œstrone for a period of a year. The rhythmical rise in the œstrone-threshold must be due either to the cyclical liberation into the blood stream of a substance (possibly from the pituitary) which in some way neutralized œstrone, or to an inherent cycle in the threshold of the tissues. It is of interest that these fluctuations were revealed not only by mature animals, but also by one that had not reached puberty at the time its ovaries were removed.

The pronounced mid-cycle fall in the degree of œstrogenic stimulation in the menstrual cycle is correlated with the removal of water from both the uterus[1] and the sexual skin[2] (a considerable amount of water may be removed from the sexual skin). The further dehydration of the uterus at the time of menstruation[1] is not improbably related to a further, but relative, fall in the degree of œstrogenic stimulation occasioned by a rise in the œstrone-threshold of the kind described above.

Nicotinic Acid and the Growth of *Staph. aureus*

Further chemical work towards the isolation of the so-called 'staphylococcus growth-factor', previously described[1], suggested that at least part of the biological activity of the high-vacuum distillate derived from yeast extract might be due to nicotinic acid and/or the corresponding amide.

The gelatin-hydrolysate basal medium already described[1] was used. *Staph. aureus* will not grow (ærobically) on this medium alone. It has now been found that addition of nicotinic acid, or its amide, will permit growth when added to this basal medium, as a substitute for the concentrated preparation from yeast (high-vacuum distillate) ordinarily used as source of the growth-factor. This distillate and nicotinic acid have the same order of activity.

The same potency is shown by different samples of nicotinic acid, namely: (*a*) nicotinic acid prepared by nitric acid oxidation of nicotine; (*b*) nicotinic acid prepared by acid hydrolysis of pyridine-3-nitrile (prepared from pyridine); (*c*) a three-times recrystallized specimen from a fractional crystallization of technical nicotinic acid (the least- and most-soluble fractions were somewhat less active).

The fact that the pyridine-3-nitrile was inactive before hydrolysis is the best evidence that it is nicotinic acid itself and not an associated impurity which is biologically active.

Nicotinic amide is more active than nicotinic acid; 0·05 γ of amide per 10 ml. of medium will permit a just visible growth.

Using the amino-acid basal medium recently described[2], nicotinic acid and the amide are inactive, whereas the high-vacuum distillate is active. This indicated therefore that the 'staphylococcus growth-factor' is complex, and that only one component of it can be replaced by nicotinic acid or its more active amide. The other component (or components) is present in limited amount in the gelatin-hydrolysate, and in the high-vacuum distillate.

Visible Mesomorphic Fibres of Tobacco Mosaic Virus in Juice from Diseased Plants

In Nature of December 19 last there appeared an interesting letter by Bawden, Pirie, Bernal and Fankuchen under the heading "Liquid Crystalline Substances from Virus-infected Plants". I have arrived at conclusions similar to some of those recorded in the above letter, and the following, to some extent complementary, observations may be of interest.

Fig. 1 (*a*) is a photomicrograph of what I consider to be fibres of tobacco mosaic virus. This conclusion is based on the following facts. The fibres developed in a sample of the expressed juice of mosaic-diseased tobacco plants which had been clarified by centrifuging and afterwards stored at about 1° C. for several months. The bulk of the juice was then found to be clear, and a dense, creamy-white, fibrous sediment of protein, which took up less than one-fifth of the total volume but which contained 97 per cent of the infective principle, had formed at the bottom of the flask. A drop of this sediment with accompanying mother liquor was taken to prepare the slide used for the photographs reproduced here.

The fibres, when undisturbed, appeared to be several centimetres long and fairly flexible, but when mounted under a cover-slip they usually broke into fragments 2–5 mm. in length. The width of individual fibres was of the order of 0·001 mm. Viewed under crossed nicols, the fibres were seen to be doubly refractive with straight extinction, as shown in Fig. 1 (*b* and *c*).

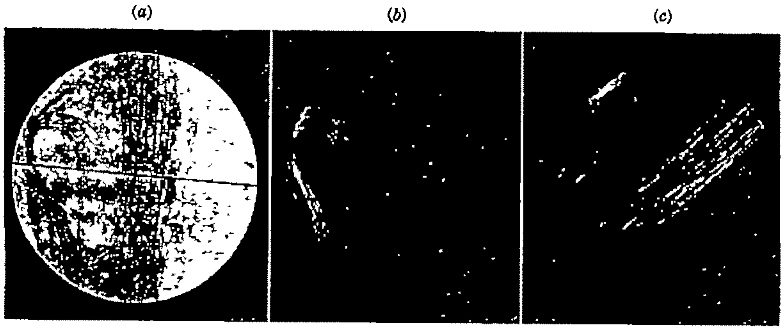

Fig. 1

a. PHOTOMICROGRAPH OF PORTION OF FIBRES FORMED IN THE CLARIFIED JUICE OF MOSAIC-DISEASED TOBACCO PLANTS AFTER THE JUICE HAD STOOD AT 1° C. FOR SEVERAL MONTHS. *b.* THE SAME FIELD AS IN *a*, PHOTOGRAPHED BETWEEN CROSSED NICOLS. *c.* THE SAME FIELD AS IN *a* AND *b* PHOTOGRAPHED BETWEEN CROSSED NICOLS AFTER ROTATING THE STAGE THROUGH 45°. ALL × APPROX. 60.

An entirely different property was observed when the fibres were viewed by reflected light. They showed up as bright white streaks when the incident light was at right-angles to their length, but were scarcely visible when the light was parallel to the fibres, suggesting a terraced structure in one direction.

By gently agitating the suspension, the fibres broke up into shorter lengths and had the appearance of short, straight needles or rods (0·1 mm. or shorter). Violent shaking reduced the greater part of them to a state where they were no longer visible (×600), and at this stage the suspension was translucent. On standing undisturbed, the process was reversed, and finally the long, satin-like fibres reconstituted and settled at the bottom of the tube, leaving a clear, supernatant liquid. This process was repeated many times without causing any apparent change in properties. The fibres were reduced to a state below microscopic visibility by quite moderate dilution.

The probability of the identity of the fibres with the infective principle was further strengthened by their behaviour when heated. The fibrous material underwent no visible change until a temperature just below 92° C. was reached, when the whole mass cleared abruptly and the fibrous, satin-like substance changed to a clumped, coagulated mass which floated to the top. The fibres were then no longer visible under the microscope and the change appeared to be irreversible. The temperature at which the fibres collapsed is also the temperature of the thermal inactivation point of this virus.

If the reaction to heat of a dense, tangled mass of the fibres is watched under the microscope, the fibres are seen to maintain their form and appearance unchanged until near the transition point, when there occurs a quivering of the whole mass, frequently followed by a general flow. The fibres then straighten and appear to become taut. This is followed by a back-and-forth movement, and suddenly the fibres break and each segment shrinks or telescopes in opposite directions. The disrupted fragments go on shrinking and collect in aggregates, leaving the formerly crowded field practically empty.

The ease with which the fibres break up on agitation, and re-form on standing to give exactly similar forms, and other properties, indicate a homogeneity of the constituent units. These fibres are not formed in the expressed juice of healthy plants which has been stored under the same conditions. Although this in itself by no means proves the virus nature of the fibres, when we consider the evidence as a whole, particularly the association of infectivity with the fibres and the identity of the temperature at which the fibres undergo a sudden, deep-seated and apparently irreversible change with the temperature at which the virus rapidly and irreversibly loses its infectivity, there can be little doubt that the fibres are composed of virus, or at least that the virus forms an essential constituent of the fibres. It seems to be a fair conclusion that these mesomorphic, flexible fibres consist of long chains of virus particles linked together by relatively feeble bonds.

The circumstance that under certain conditions the fibres have the appearance of short needles or rods raises the question as to whether the needles obtained by crystallization from ammonium sulphate solution, as first worked out by Stanley[1], may not in fact be short mesomorphic rods rather than true crystals.

The deduction by Bawden, Pirie, Bernal and Fankuchen of the presence of long fibres in their systems, is thus confirmed by my direct observation of the existence of such fibres.

Adsorption on Foam

SINCE surface active substances are among the most active pharmacologically (Michaelis and Rona[1]) we may expect that surface active substances in the organism may be likewise of great importance. It occurred to me that the adsorptive capacity of the great surfaces of foams might be employed in the concentration of such substances, and I have developed a simple technique for this purpose.

The apparatus[2] is outlined in Fig. 1. The liquid to be examined is placed in *C*. Air or an inert gas is bubbled through the liquid by means of the capillary tube *A* which ends in a fine jet *B*. The tube *A* is sealed into the ground glass junction *E*, and may be interchanged with other tubes having various bores. The gas pressure is adjusted so that the foam produced by the bubbles passes slowly over into the a receiver *D*. *C* and *D* are connected by a ground glass junction *G* which allows the interchange of receivers, so that *different fractions of the foam* may be removed. The liquid formed in *D* (denoted by *F*) by the settling of the foam, may now be compared with the original solution (denoted by *O*), and the remainder of the solution in *C* (denoted by *R*). In an experiment with saponin, 1 ml. of the solution *F* was calculated to have had a total superficial area of about 32 m.[2] when in the foam state, which area corresponds to the thickness indicated by the appearance of interference colours.

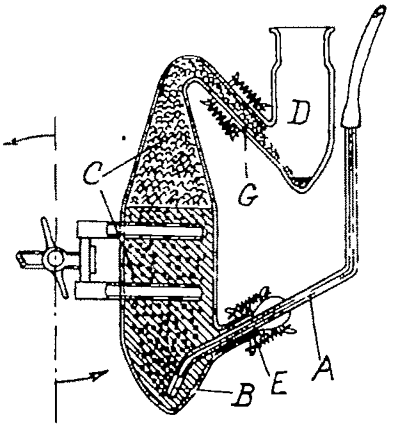

Fig. 1.

The surface tension of the solutions always shows the following relationship: $R>O>F$. By experiments on sodium cholate, carried out in collaboration with R. Bader, it has been shown that there is a concentration of the cholic acid (furfurol-test, Pulfrich photometry[3]) in the liquid formed from the foam (*F*), which contains up to 65 per cent more of the acid than *O*. Further, it proved possible to separate cholic acid from Na-cholate by this method. A precipitate always formed in the earlier *F*-fractions, which proved to be pure cholic acid. No precipitate ever formed in *O* or in *R*.

In most cases the *p*H of *F* and *R* was different from the *p*H of *O*. For example, when *O* is rabbit serum or Na-cholate, *F* tends to become acid, *R* to become alkaline. When *O* is saponin the change in *p*H is in the opposite direction. This apparently means that all the ions are not equally adsorbed on the foam surface. In the case 0·5 per cent Na-cholate solution, the difference in surface tension (σ) between the *F* and the *R* is about 6–8 dynes/cm., the difference in *p*H is about one unit. In the case of 0·02 per cent saponin solution $\Delta\sigma$ is up to 20 dyne/cm., ΔpH about 0·6 unit. Measurements of *p*H were made with a glass electrode, surface tension by the ring method (Lecomte du Noüy's automatic tensiometer[4]).

In collaboration with H. Mann it was further found that the foam has a higher temperature than the liquid from which it is produced (when the gas has the same temperature as the liquid). This effect seems to be a necessary condition for the formation of any foam. The effect would appear to agree with the principle of Braun and Le Chatelier, since in the case of all the substances examined, the production of foam becomes more difficult as temperature increases. The temperature difference (ΔT) between foam and liquid is greater for low concentrations of capillary active substances than for high concentrations. In the case of 0·01 per cent saponin solution, $\Delta T = 3{\cdot}3°$ C.

In collaboration with G. Kolmer it was found that hæmoglobin is less concentrated in the first fractions of *F* than in *O*, but more concentrated in later fractions of *F*, when *O* is a mixture of hæmoglobin and serum. It would seem that substances differing from each other as regards capillary activity pass over one after the other in the various fractions. In collaboration with H. Lassner it was found that the complement and antibodies (hæmolysines) of rabbit serum are not destroyed in the foam.

Detailed reports will appear shortly.

Absorption Spectrum of the Carboxyl Group in the Vacuum Ultra-Violet

WE have recently been investigating the far ultra-violet absorption spectra of a number of organic compounds of the type R_1COOR_2; R being an alkyl group or a hydrogen atom. It has been found that only the simplest of these, namely formic acid, shows discrete absorption bands in the region 2000–1000 A. The interpretation of the electronic structure of the carboxyl group will therefore depend to a considerable extent upon the analysis of these discrete bands.

The first strong absorption of formic acid starts around 1550 A., at which wave-length a set of somewhat diffuse bands appear. Between 1400 A. and 1100 A. the bands are sharp. The analysis shows that they consist of a number of electronic transitions each of which is represented by a short vibrational progression of two or three members. These pr[illegible]gressions are strong and well separated at long wave-lengths, but become weaker and overlap towards shorter wave-lengths, eventually merging into a continuum around 1100 A. A plausible Rydberg series formed from the ν_0's of the progressions has its limit just about where the continuous absorption begins, namely, 11·2 volts. This value may be compared with the value 10·83 volts obtained for the ionization potential of formaldehyde by a similar method[1].

Mulliken[2] has shown that the latter ionization potential is to be associated with the removal of a non-bonding 2*p* electron from the oxygen atom of the C=O group. He also states that the absorption spectra of the organic acids and esters should resemble the aldehydes and ketones in this respect. The closeness of the two ionization potentials seems to confirm his view. In fact, below 1600 A. a definite correspondence has been found between the electronic transitions of formaldehyde and formic acid; the related bands of both molecules occurring in the same wave-length regions. While there are no analogues in the spectrum of formic acid to the formaldehyde bands at 3000 A. and 1750 A., it must be pointed out that these latter bands are not included among the Rydberg bands of that molecule. Actually their upper states have been assigned to certain anti-bonding orbitals which are apparently suppressed by the presence of the O–H group.

Further evidence that the ionization potential reported here is to be attributed to an electron from the carbonyl group comes from the fact that the strongest vibration frequencies accompanying the excitation were found to have values lying between 1400 and 1500 cm.$^{-1}$. A consideration of the intensity distribution in the progressions shows that they correspond to the vibration 1647 cm.$^{-1}$, of the unexcited state[3]. This is the valence frequency of the C=O bond. Thus we have both the vibration and the excitation occurring in the carbonyl group.

In addition to the bands reported above, some very diffuse (pre-ionized) bands were found in the region below 1100 A. superimposed on the ionization continuum. These may well be due to the excitation of non-bonding electrons from the O–H group. However, it was not possible to make sufficiently accurate measurements on them to justify an analysis.

A Sensitive Adaptation of the Spoon Gauge

THE spoon gauge is probably the most satisfactory and easily constructed instrument available for the accurate measurement of pressure differences when the use of a manometric liquid is not permissible. Its sensitivity, however, is limited to a pointer movement of about one millimetre for each millimetre of mercury pressure, or perhaps a little more with very fragile gauges. We describe below an effective design which shifts the sensitivity several decimal places into the high vacuum range.

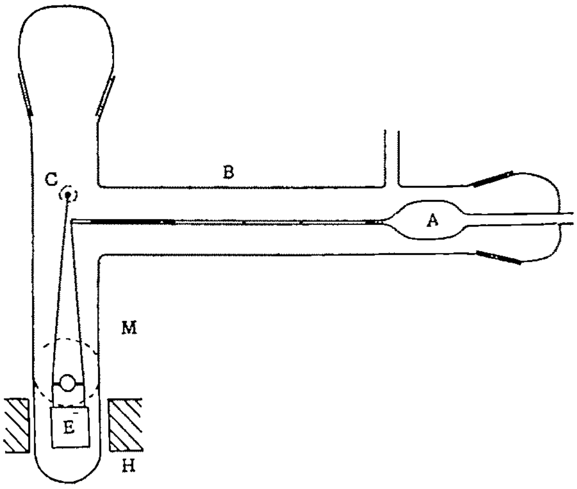

Fig. 1.

The essential feature of the device is a special form of bifilar suspension, which permits amplification of the movement of the pointer end. This suspension consists of unequal and non-parallel threads, the supports of which, placed one above the other, can be brought as closely as desired to the same vertical line. One support is the pointer end, and the other is a movable arm controlling the sensitivity. The threads, spreading out downwards, so as to clear the lower obstructing arm, carry on their ends a horizontal beam to which is attached a mirror and damping device.

The sensitivity depends on the effective horizontal separation of these supports, and this distance can be reduced to less than the thread diameter. Using comparatively rough methods and the usual mirror and scale distances, a magnified movement of about ten thousand-fold is obtainable. With refined methods this figure could be considerably improved.

The particular gauge described below, although simple and convenient in construction, had a sensitivity exceeding one ten thousandth of a millimetre of mercury, and was almost entirely free from vibrational disturbances. A large vertical tube *M* in Fig. 1, housing the suspension, carries two horizontal tubes at right angles, the lower one *B* containing the 20 cm. spoon gauge *A*, and the upper one *C* ending in a ground joint. In this joint could be rotated a slightly eccentric glass arm ending above the tip of the gauge pointer. Long fibres of silk are first attached to the suspension unit, which is lowered into the tube *M*. With each thread touching a support, the beam is adjusted to oscillate axially in the tube about a line parallel with the gauge pointer. The fibres are then sealed to the respective supports with apeison wax and the upper superfluous portions cut short with a hot wire. The sensitivity is raised by rotating sufficiently the cranked rod, and finally all joints are sealed with apeison wax.

The suspension unit consists of a light glass beam, carrying a galvanometer mirror facing a window, and below is fixed a light cylinder of aluminium foil *E*. This rotates in the field of the electromagnet *H*. With critical damping a pressure change is registered with the required accuracy in about two seconds—the natural period of the suspension. The spot light remains stationary within half a millimetre even with the thermostat stirrer running vigorously.

It was found that the zero reading varied somewhat with the magnetic field, due presumably to the magnetic properties of the aluminium vane. For critical damping this amounted to sixty millimetres, and care was taken to maintain a constant field.

This spoon gauge had normally a sensitivity of 8 mm. movement of pointer tip for a pressure change of 10 mm. of mercury. When erected with the scale at two metres from the mirror, the gauge had a sensitivity of 1 mm. deflection for 4×10^{-5} mm. of mercury pressure. This indicated a horizontal separation of the points of suspension of 0·13 mm., which distance is about the minimum that can be easily obtained with the simple arrangement described.

This principle may be used to magnify any horizontal movement.

Molecular, Nematic and Crystal States of 1 : 1′-Diethyl-ψ-Cyanine Chloride

ATTENTION has been directed in NATURE[1] to a recent publication by Scheibe, Kandler and Ecker[2] concerning the narrow absorption and fluorescence band exhibited by certain solutions of the dye 1 : 1′-diethyl-ψ-cyanine* chloride, in which these authors, on the basis of viscosity measurements, express the view that the effect is due to a reversible polymerization of ions of the dye. Since the publication of a previous note[3], in which I have suggested that the narrow absorption band is characteristic of the molecular state, the ageing of aqueous solutions of 1 : 1′-diethyl-ψ-cyanine chloride containing various concentrations of sodium chloride has been studied by the concurrent application of spectrographic, ultra-microscopic and streaming birefringence methods.

---

* This dye is termed 1 : 1′diethyl-ψ-isocyanine in the German publication.

Four distinct phases have now been recognized.

1st Phase. Dye in true solution.

2nd Phase. Absorption spectrum changes from that of cationic dye to give a very sharp 'molecular' band at 573–574 mμ; very strong fluorescence; uniform luminescence without structure seen with ultra-microscope; no streaming birefringence. This phase is rapidly succeeded by the

3rd Phase. The 'molecular' absorption band at 574 mμ shifts towards the red, and becomes less sharp as the preparation ages; fluorescence progressively weakens, and, when excited by plane-polarized light shows partial polarization, whereas the fluorescence similarly excited during the second phase is not polarized; the ultra-microscope shows a fine thread-like structure of a brilliant greenish yellow colour. The threads grow in thickness from about 5 mμ to 500 mμ, while streaming birefringence rapidly increases. This phase also shows powerful streaming dichroism.

4th Phase. After some weeks, normal prismatic crystals of the dye are formed.

Crystals of the dye, less than 1μ thick, exhibit the following trichroism:

Vibrations ∥ to	Colour	Absorption	Surface Colour
$X = n_\alpha$ for red	Pale yellow	General in blue	Pale violet
$Y = n_\beta$	Bluish pink	Sharp maximum at 579 mμ	Intense yellow
$Z = n_\gamma$ for red	Dark brownish red	General from yellow to blue	Bluish violet

The crystals occasionally form slender needles by elongation along *Y*, and consequently appear bluish pink for vibrations along their length, and any shade from very pale yellow to dark brownish red for vibrations at right angles, according to their orientation. The crystals are not fluorescent.

The optical properties of the threads of the third phase differ in four respects from those of the needle crystals.

(1) The threads are strongly fluorescent, the fluorescence being plane-polarized with vibrations in the length of the thread.

(2) The absorption of light vibrating parallel to the length of the thread at first shows a very sharp maximum at 573 mμ, which flattens and moves towards the red as the preparation ages, ultimately becoming identical with that of the *Y* direction of crystals. The threads appear bluish pink for this vibration direction.

(3) The absorption of light vibrating perpendicular to the length is independent of the orientation of the threads, which appear pale orange for such vibrations.

(4) The birefringence is of the same sign for all orientations of the threads, so that the birefringence of threads crossing at a very acute angle is always additive, whereas with random orientations of needle crystals crossing at an acute angle, partial or complete neutralization often occurs.

The threads appear to be true crystals in one dimension (*Y*) only, for the abnormalities 3 and 4 above are accounted for if we assume that the molecules have either free rotation, or else a random orientation, about the *Y* axis. It is therefore highly probable that the threads of Phase 3 are strictly analogous to the nematic form of 'liquid crystal'. The viscosity abnormalities noted by Scheibe, Kandler and Ecker are therefore explained, not by "polymerization of dye ions" but by the existence of nematic aggregates of dye molecules. The sharp absorption band and associated fluorescence is a characteristic of electronic transitions of individual molecules and their nematic aggregates.

Precise Distribution of *Mercurialis perennis* according to Soil Hydrogen Ion Concentration

In a wood covering several acres on the Lower Greensand of Surrey, *Mercurialis perennis* (dog's mercury) appeared to be distributed in an irregular way, in patches which clearly were not determined by the light intensity alone. In one case it was abundant along the lower side and absent along the upper side of a track that ran across a gentle slope. The pathway had been made up with chalk, and it was clear that the sandy soil below the path had become a possible habitat for *Mercurialis* because of the washing down of solid calcium carbonate and probably of dissolved bicarbonate as well. The whole region covered by the wood bears scattered patches of chalky soil, owing to transport of chalk for agricultural use and in making up trackways.

Determinations of hydrogen ion concentration were made on soil samples from eight pairs of sites scattered in various parts of the wood. The two sites of each pair were not more than three metres apart (generally within one metre) one being in a patch of *Mercurialis* and one on ground where it was absent; and each sample was taken from a spot where it was obvious that light was quite adequate but not too strong for the growth of *Mercurialis*.

The *p*H of the eight samples bearing mercury had a mean of 6·3, the values varying between 7·3 and 5·5; (free carbonate was present in the only two samples with a *p*H above 7·0). The *p*H of the eight samples from sites with no mercury had a mean of 4·8, the values varying between 5·5 and 4·4.

The absence of *Mercurialis perennis* from soils with a low quantity of exchangeable calcium has been shown by De Silva[1] and by Mukerji[2], and it needs no substantiation. Likewise De Silva has reported the local occurrence of *Mercurialis* on a spot which had recently been given a higher base status by the dumping of rubbish. What is interesting about the records given here is not so much that the spots bearing *Mercurialis* have a high *p*H, as that the similar spots tested where there was no *Mercurialis* all showed a distinctly lower *p*H, that is, that *Mercurialis* has become distributed to all (generalizing from the data collected) the adequately lit spots where the edaphic factors make its growth possible. This is, of course, a state of affairs which one would expect, particularly in a species readily dispersed and not hampered by an already closed community, and its truth is generally assumed; but as one rarely sees data which prove the point, it seems of interest to recount the facts given above, which serve as a proof for this particular case and within the limits of the rough method adopted.

Absorption of Strain Energy in Metals

WHEN a metal is strained, the work done is partly stored up as strain energy and partly used up by internal absorption. The ratio (φ) of the energy absorbed to the energy stored is a constant, characteristic of the material, but sensitive to changes in structure and temperature. It is often assumed that the absorption can be represented by a damping force proportional to the velocity of deformation, but such an assumption is not in agreement with the experimental facts.[1]

There appears, however, to be a linear relation between the Debye temperature θ of a metal and the logarithm of φ. This is shown by the graph below in which the values for Debye temperatures (calculated from specific heats) have been taken from the "Handbuch der Metall-Physik", vol. 1, p. 252 (Leipzig, 1935), and the values of φ from a paper by A. L. Kimball and D. E. Lovell[2]. It should be noted that apparently Kimball and Lovell took no special precautions to ensure constancy of temperature.

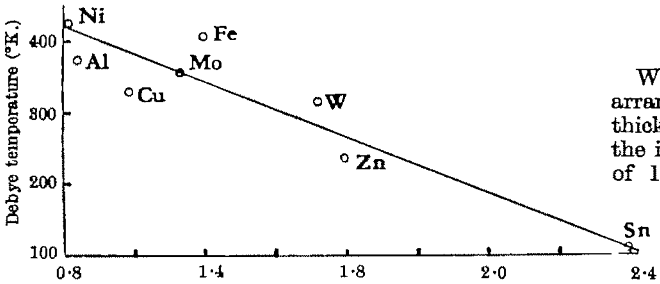

Fig. 1.

This relation suggests that the process of absorption may be one of scattering of phonons of elastic strain energy by those atoms or molecules which are vibrating at the Debye frequency. Such a process would be analogous to the scattering of photons in the Raman effect.

Electrical Stimulation of the Cochlea

IF the external auditory meatus is filled with saline solution and an alternating current is passed through the ear by means of an electrode immersed in it, a tone is heard. The pitch is determined by the frequency of the alternating current and may correspond to its fundamental or first harmonic[1,2,3,4,5,6]. If at the same time the stem of a vibrating tuning-fork is placed on the head, it is easy to obtain regular beats by adjustment of the A.C. frequency. This shows that the 'electric' stimulus and the bone-conducted stimulus travel along a common pathway before they enter any all-or-none-mechanism. As v. Békésy[7] has shown the same regarding air conduction and bone-conduction, it is clear that in electrical stimulation of the cochlea the same peripheral mechanism is involved as in stimulation by air-borne sounds.

This seems to give further support for the 'movement' theory advocated by Stevens[5] and by Hallpike and Hartridge[6]—but only if one assumes that pitch-discrimination in normal hearing is effected by mechanical resonance (which, incidentally, is my belief). It may, however, be pointed out that even if pitch-discrimination were effected by electrical resonance *ad modum* Zotterman[3], one should expect the transient effects described by Hallpike, Hartridge and Rawdon-Smith[8]. As is well known, the behaviour to transients of a resonator of given pitch and selectivity is the same, whether it is constructed from electrical or mechanical components.

Diurnal Variation of Cosmic Ray Shower

WITH a three-fold coincidence apparatus, counters arranged in a triangle and with a lead plate 1·5 cm. thick placed above the upper counter, I have registered the intensity of a cosmic ray shower during a period of 110 days. The result of these measurements, performed at sea-level, does not show any connexion between the variation of the shower-intensity and the diurnal periodicity of the horizontal intensity of the earth's magnetic field, as is the case with vertical coincidences[1].

Assuming that a primary shower produces radiation composed of electrically charged particles, we should expect under the influence of the earth's magnetic field a much larger diurnal variation, for the greater barometer effect of the shower seems to suggest that the shower-producing primary radiation is softer than the radiation producing the vertical coincidences. The non-existence of any correlation between shower intensity and the earth's magnetic field can likewise be interpreted in the sense that the primary shower-producing radiation is not composed of electrically charged particles. On the other hand, the experiments indicate a very good agreement between the variation of the shower intensity and that of the temperature of the outer air; both having a maximum in the late afternoon. (Priebsch found at 2,300 m. altitude the maximum of the daily period to be at noon[2].) The positive correlation coefficient between shower intensity and temperature was found to be $r = 0{\cdot}72 \pm 0{\cdot}10$, and the temperature effect $TE = 0{\cdot}074 \pm 0{\cdot}010$ per cent per degree C.

The measurements were performed through the kind assistance of the Hungarian Council for Natural Science.

Potential Constants of Tetrachlorethylene

IN my recent letter to NATURE on this subject[1], the values of f and γ which I have deduced from Delfosse's theory are erroneous. They should be replaced by the following: $f = 4{\cdot}48 \times 10^5$ dynes/cm.; $\gamma = 0{\cdot}65 \times 10^5$ dynes/cm.

It should be noted that f is greater than γ, which is in accord with ordinary chemical conceptions.

Finally, the values of ν_4 and ν_8 and of ν_4^* and ν_8^* should be interchanged.

These values will then read as follows:

$$\nu_4 = 236 \text{ cm.}^{-1}; \quad \nu_8 = 1569 \text{ cm.}^{-1}.$$
$$\nu_4^* = 230 \text{ cm.}^{-1}; \quad \nu_8^* = 1569 \text{ cm.}^{-1}.$$

The conclusions reached in the letter are, however, unchanged.

Points from Foregoing Letters

Commenting on the effects, observed by Harkins and Myers, of minute traces of metallic ions upon monomolecular films, Dr. J. S. Mitchell, Prof. E. K. Rideal and Dr. J. H. Schulman point out that minor traces of metallic ions 'sensitize' chemical processes in monolayers and affect the electrical protential at phase boundaries. This fact may be related to the biological action of the metals. Dr. C. Robinson describes the lowering of the interfacial tension between oil and water, in presence of salts of long-chain acids, due to calcium ions present as impurities in distilled water.

H. Christensen, M. Krogh and M. Nielsen suggest that symptoms of mercury poisoning may result from the presence of mercury spilled on the floor in poorly ventilated rooms.

The formation of ammonia in a series of stages, in shed blood, is described by Prof. E. J. Conway and R. Cooke. The authors also find that the blood (both plasma and red corpuscles) contains a powerful enzyme capable of splitting off ammonia from adenosine.

A phenol derived from the essential oil of anethole (*p*-hydroxy propenyl benzene) is found by Prof. E. C. Dodds and W. Lawson to possess an œstrogenic activity approaching that of the sex hormone œstrone. The authors give a table showing the activity of several other compounds, proving that the phenanthrene nucleus is not an essential part in the molecule of an œstrogenic substance.

B. C. J. G. Knight reports that one of the 'growth factors' present in the high-vacuum distillate of yeast, which enables *Staphylococcus aureus* to be grown on a special 'basal medium', can be replaced by nicotinic acid or its amide.

The formation of visible mesomorphic fibres in clarified, expressed juice of mosaic-diseased tobacco plants is reported by R. J. Best. The fact that infectivity is associated with the fibres, together with the fact that the fibres collapse at the temperature of the thermal inactivation point of the virus, and other properties, lead to the conclusion that the fibres are the virus, or at least that the virus forms an essential constituent of the fibres. It is considered that the fibres consist of long chains of virus particles linked together by relatively feeble bonds.

A technique for the concentration of capillary active substances from composite liquids by the use of foam is described by Dr. Franz Schütz. A difference in the degree of adsorption of certain ions on foam is shown to take place and with it a change of pH and surface tension in the liquid formed by the settling of the foam and in the original solution. Other phenomena, including a new physical temperature effect in connexion with foam, are discussed.

A device for increasing the sensitivity of the 'spoon gauge' for measuring pressure differences, the essential feature of which is a special form of bifilar suspension, is described by A. Lewis and Dr. D. W. G. Style. This enables a pressure difference 4×10^{-5} mm. of Hg. to be read on the scale.

By the application of spectrographic, ultramicroscopic and streaming birefringence methods to the study of dispersions of 1 : 1′-diethyl-ψ-cyanine chloride, in sodium chloride solutions, Dr. E. E. Jelley has found that the dye passes from the dissociated state through a molecular phase of very brief duration to form very thin threads. From a study of the optical properties of these threads, and of very thin needle crystals of the dye, he has deduced that the threads are crystalline in the direction of their length only, and correspond to the nematic type of liquid crystal.

The apparently haphazard distribution of certain plant species over a small area may really reflect very exactly the variations in the conditions of the habitat. This was observed by J. F. Hope Simpson to be the case with *Mercurialis perennis* (dog's mercury) in a wood the soil of which showed marked variations in hydrogen ion concentration.

An experiment showing that the stimulus produced by an alternating current in a saline-filled ear can be combined with that produced by a vibrating tuning fork to give 'beats', is described by E. Bárány. This, the author states, shows that the electric stimulus and the bone-conducted stimulus travel along a common pathway before they enter any all-or-none-mechanism.

Unlike the intensity of cosmic rays themselves, the number and intensity of showers produced by the cosmic rays at different times of the day is not related to the intensity of the horizontal component of the earth's magnetic field. This, Dr. M. Forró states, may indicate that the primary shower producing radiation is not composed of electrically charged particles.

Research Items

Racial Crosses in Cape Verde Islands

PROF. A. A. MENDES-CORREA, director of the Institute of Anthropology, Oporto, took advantage of the presence of some three hundred natives of the Portuguese Colonies at the Colonial Exhibition at Oporto in 1934 to make a series of observations of their anthropological characters. Among them were nineteen cross-breeds from the Cape Verde Islands, of whom all with the exception of two were more than twenty years of age. Thirteen were male and six female. As the people of these islands have been little studied, the results (*Z. Rassenkunde*, 5, 1) are of no little interest. The population of the islands is 150,553, of whom 5,794 are white, 40,154 black, and 104,605 mixed. The subjects observed had dark brown skin, dark eyes and dark brown ulotrichous hair. One woman and two men showed wavy hair. The prominence of the cheek bones was marked in the majority of men and most women. The face was very variable. Three men and one woman showed a certain obliquity of the eyes. The nose was straight in profile, and was not long. The nostrils were elliptical, almost round, with the longer axis transversal. Only four men had a stature over 1·650 m. The number is too small for the mean of 1·702 m. to have significance. The female stature varied from 1·520 to 1·680 m. There appeared to be a tendency to exceed the Portuguese mean. The skelic index also appeared to approach the negro, rather than the Portuguese. A number of measurements taken on the upper and lower extremities pointed in the same direction, the measurements being on the whole intermediate between Portuguese and negro (Guinea), but on the whole inclining towards the latter. The cephalic index of the men varied between 74·4 and 84·1, while among the women it varied from 71·4 to 84·2. As compared with Portuguese and negro, the figures show a tendency to an increase, which it is not easy to explain. Is it a result of admixture, as certain investigations on other peoples seem to show ?

Beavers in Michigan

DURING the open season of 1936 (March 16–31 in Lower Peninsula and April 1–15 in Upper Peninsula) 137 bodies of beavers (*Castor canadensis michiganensis*) trapped in Michigan were examined by Seth B. Benson (*Occas.* Papers Mus. Zoo. Univ. Michigan. No. 335, June 1936). Contrary to the opinion of trappers that males largely predominate among beavers trapped in spring, it was found that the sex ratios were practically equal, 51·8 per cent females, 48·2 per cent males. Measurements and weights showed that the animals fell into two groups, a yearling class, and two-year-olds with adults. The yearlings formed 59·1 per cent of the catch, 25 per cent were two-year-olds, and the remaining 15 per cent were three-year-olds or older. None of the yearling females was pregnant, and the appearance of the uteri suggested that they do not breed. There was some indication also that some two-year-olds do not breed, or, if they do, that it is later in the season than March and April. Of the 34 adult females, 21 or 61·7 per cent contained embryos, some being almost full term. Although the author does not allude to the fact, it seems unfortunate that the open season should coincide with a period when so many females are about to produce young.

Biology of Arctic Marine Invertebrates

IT has long been known that reproduction by direct development is a characteristic feature of bottom invertebrates in arctic seas. A recent publication by Gunnar Thorson has shown how prevalent this is ("The Larval Development, Growth, and Metabolism of Arctic Marine Bottom Invertebrates", *Meddelelser om Gronland*, 100, No. 6; 1936). A study of the bottom fauna and the plankton was made throughout the complete year in fiords in north-east Greenland. In all, about two hundred species of polychætes, echinoderms, molluscs and crustaceans were studied. Of these, it was found that ninety-five per cent reproduced without true pelagic larval stages, the majority having very large yolky eggs. These were all purely arctic species, and the remaining five per cent, which had pelagic larval stages, were species not confined to the Arctic; these occurred in the plankton during the short period when food was most available. It is noteworthy that in north-east Greenland it was these latter species which were quantitatively commonest in the area. Examination of oxygen consumption was made, mostly on lamellibranchs, and it was found that they had a fairly high oxygen consumption compared with more southerly species at the same temperature. But at the temperatures at which they live respectively, the arctic species had a somewhat lower consumption than the southern. A comparison is made between the biology of the arctic fauna and those from other regions, and the origin of the arctic shore fauna is discussed. The paper is an important contribution to our knowledge of the biology of arctic marine animals.

Cirripedia of the Arabian Sea

A LARGE number of cirripedes are described by Mr. H. G. Stubbings (Cirripedia. The John Murray Expedition 1933–34. Scientific Reports. Vol. 4, No. 1. British Museum (Natural History), 1936). Two areas, the Zanzibar area and the Gulf of Aden, stand out as being specially favourable, twenty species out of forty-three collected by the expedition coming from the first, and thirteen from the second, only two species being common to both. Farther north along the South Arabian coast cirripedes were much scarcer. As is to be expected in such a deep sea collection, the genus *Scalpellum* and its subgenera predominate, fourteen species being represented. The geographical and bathymetrical distribution of *Scalpellum* is discussed, and it is shown that *S. velutinum*, which has a very wide distribution, ranges from 50 metres to 2,900 metres, but lives mainly between 600 metres and 2,000 metres. Several dwarf males were found on this species and a series of growth forms from newly metamorphosed cypris stages together with the cypris stages themselves. Dwarf males and growth stages were also found in various other forms. Among the specially interesting species are *Oxynaspis* *aurivillii* overgrown with polyps of an antipatharian, and several species growing on Crustacea. Amongst the latter are three species of *Pœcilasma* all growing on the crab *Echinoplax pungens* which is a favourite host, and one of these also growing on the palinurid *Puerulus angulatus* from the Gulf of Aden. Five new species are described, three *Verruca* and two *Balanus*.

Use of the Developing Egg in Virus Research

VIRUSES are unable to multiply apart from living cells, and the maintenance of a virus in the laboratory after isolation has, therefore, depended upon inoculation for the most part, though tissue-culture methods, particularly those devised by H. B. and M. C. Maitland, have proved useful, but have replaced the living animal only to a limited extent. During the last four or five years, it has been shown that the chorio-allantoic membrane of the developing hen's egg is suitable for the cultivation of most, if not all, viruses, and solves many of the difficulties connected with their study. This work has been especially pursued by Dr. F. M. Burnet, who has now written a monograph on the subject (Medical Research Council, Special Rep. Series, No. 220. London: H.M. Stationery Office, 1936. 1*s*. net). This gives the full technique of the method, which is comparatively simple, surveys the published work on the subject, and contains many new observations and suggestions. It is surprising how many viruses can be cultivated by the method; by serial passage, it has even been possible to adapt the virus of epidemic influenza to the egg-membrane, which seems to constitute an ideal medium for virus study, as well as being cheap and requiring a minimum of attention. The chorio-allantoic membrane also provides a tissue of simple structure in which to study the histological changes that may be caused by a virus infection.

Fire Blight of Apples and Pears

THE bacterial disease caused by *Erwinia amylovora*, and known as fire blight, has been a serious menace to apple and pear trees in America for more than half a century. Many studies of the disease and the pathogen have been made, and a recent publication by Dr. K. G. Parker (Cornell Univ Agr. Exp. Sta. Mem. 193, August 1936, Ithaca, N.Y.) describes further investigations upon the overwintering, dissemination and control of the malady. Large cankers appear upon the branches of infected trees, or are brought to the orchard upon grafting material. The activity of the bacteria within such cankers causes an ooze of infectious material, which may be disseminated to healthy shoots by rain or by insects. Several species of flies, and ants, stand incriminated in this respect. A few bacterial organisms which are antagonistic to *E. amylovora* have been found, and some of them can inhibit the infection of blossoms when inoculated along with the pathogen. Disinfection of the overwintering cankers seems to be the obvious method of control, and solutions of cadmium sulphate have been found most suitable for this purpose.

Refrigerated Gas-Storage of Fruit

SINCE 1929, the capacity of gas stores in England has risen from negligible proportions to more than two million cubic feet in 1936—a capacity not far short of a million bushels of apples. The time is thus opportune for the survey of the development of refrigerated gas-storage methods presented by Drs. F. Kidd and C. West (*J. Pom. and Hort. Sci.*, 14 (4), 299; 1937). The principles underlying the method are given, the considerations governing the construction of gas-tight chambers and the methods of controlling the composition of the storage atmosphere. The following advantages of gas-storage of apples over cold storage in air have been established. (1) Ripening of the fruit at a given temperature proceeds at half the rate in air, that is, the life of the fruit in store is twice as long; (2) low-temperature breakdown is avoided because temperatures are used above the limit at which this develops; (3) firmness of the fruit is preserved almost unchanged over long periods of storage; (4) change in ground colour from green to yellow is markedly retarded; (5) *Tortrix* moth larvæ are quickly killed in gas storage; (6) life of the apples after removal from gas storage is remarkably long. An account is given of the normal behaviour of apples after gathering and the influence on this behaviour of temperature, oxygen and carbon dioxide concentration and volatile substances. The information so far available refers particularly to apples and pears, but there seems every possibility that similar methods may be applicable with equal success to plums, peaches, grapes and citrus fruits.

First Crossing of Antarctica

A NOTEWORTHY event in the history of Antarctic exploration was Mr. Lincoln Ellsworth's flight across Antarctica in 1935, a distance of 1,842 nautical miles, from Snow Hill Island, Graham Land, to Little America on the Ross Sea. Mr. Ellsworth's own account, accompanied by a provisional map, appears in the *Geographical Journal* of March. His aeroplane, the *Polar Star*, was large enough to carry fuel for a range of 5,000 miles if only fuel and oil were required and had a 600 h.p. engine and a possible speed of 215 miles per hour. Much of the load, however, had to consist of two months' equipment and supplies for two men. Thus when he took off, the loaded *Polar Star* weighed 7,987 lb., of which 3,614 lb. was the load of the aeroplane and 2,796 lb. (466 gallons) the load of petrol. This was just enough fuel to carry the *Polar Star* across, with four landings on the way. At the final landing, sixteen miles from Little America on the Bay of Whales, the fuel was completely exhausted. Several features of importance were noticed on the way. Stefansson Strait of Wilkins appears to be not more than three miles wide and might even be a fjord and not a strait. This seems to be in accordance with Mr. Rymill's recent discoveries farther west. Eternity Range, south of the strait, showed bold rugged peaks rising to 12,000 ft., in contrast with the lower, flatter summits of Graham Land. Farther on, this range gave way to scattered nunataks and then, in about lat. 78° S., long. 85° W., was sighted the lofty Sentinel Range. Thereafter stretched an apparently unbroken ice-covered plateau at an elevation of about 6,000 ft. to Marie Byrd and Edward Lands.

Sea Breezes

AT a meeting of the Royal Meteorological Society held on February 17, Dr. R. C. Sutcliffe gave the results of an analysis of ten years observations of the wind up to a height of 5,500 feet, made with the aid of pilot balloons at Felixstowe, with the object of studying the behaviour of the sea breeze at various levels. In order to eliminate days unfavourable for a full development of the sea breeze, those days on which the duration of sunshine shown by a Campbell-Stokes sunshine recorder was less than 70 per cent of the possible duration for the time of year were omitted. The mean direction of the coast at Felixstowe, it may be noted, is from south-west to north-east, a south-east wind being, therefore, an on-shore wind. It was found that when a sea breeze replaces a land breeze as the day advances towards the hottest time, the vector change of speed at right angles to the coast is about 15 m.p.h. on an average up to a height of 500 ft., but is less higher up, becoming very small above about 1,500 ft. Although the average depth of appreciable sea breeze is therefore only about 1,500 ft. at Felixstowe, no definite evidence of a compensating return current was found higher up. The component along the coast behaved so that there was a tendency towards a geostrophic wind in the afternoon, the land being on the left, as though it were a region of low pressure; this coastal component averaged about 5 m.p.h. near the surface, except in the case of northerly winds. With a general inshore wind not due to sea breeze, there was very little increase in the landward component towards the hottest time of the day, but there was a backing of the direction.

Air Temperature during Total Solar Eclipses

IN *Mon. Not. Roy. Astro. Soc.*, 97, 2 (Dec. 1936), Dr. John L. Haughton has a paper in which he describes the apparatus used by him for determining the fall in temperature during the total solar eclipse of June 19, 1936. The instrument responded very rapidly to change of temperature, and it was possible to read to about 0·1° C. by means of the millivoltmeter (1 mv. = 2·1° C.). The maximum fall from a curve indicating what the temperature might have been if there had been no eclipse was only 1·5° C., and Dr. Haughton thinks that this small fall can be accounted for by the low altitude of the sun and the thermostating effect of the large mass of water. (The observation was taken on board the S.S. *Strathaird.*) When we hear of 'the great fall in temperature' in the case of some eclipses, this is, Dr. Haughton thinks, a fall in radiation temperature, not in air temperature. Comparisons are made between the fall in temperature during this eclipse and the fall in the case of the eclipse of 1927 and also of 1932; but owing to the different conditions, accurate comparisons are impossible, so that the table showing the results has little value.

Composition of the Atmosphere

THE constancy of the percentages of carbon dioxide and oxygen in uncontaminated atmospheric air was established by Benedict in 1912. T. M. Carpenter has now described (*J. Amer. Chem. Soc.*, 59, 358; 1937) several hundred analyses of air made in the period 1930–36 in New Hampshire, Baltimore and Boston. The apparatus was capable of giving burette readings to 0·001 per cent. The grand average of all three series gave 0·031 per cent for carbon dioxide and 20·939 per cent for oxygen. In spite of widely different local conditions of the three laboratories, there was no evidence that variations in season or proximity of large consumers of fuel caused any measurable differences in the carbon dioxide and oxygen content in the atmospheric air. The Boston laboratory is situated near a large power station and that in New Hampshire near a heavily wooded locality. The deviations from constant values found were very small, the percentage of oxygen having a constancy beyond the accuracy of many atomic weight determinations.

Oxidation of Coal

B. JUETTNER, R. C. Smith and H. C. Howard (*J. Amer. Chem. Soc.*, 59, 236; 1937) have examined the oxidation with alkaline permanganate of a Pittsburg bituminous coal and of a 500° coke made from it. It is shown that 90–95 per cent of the carbon can be recovered in the form of water-soluble, non-colloidal acids, of which aromatic acids correspond with 30 and 35 per cent, respectively, of the carbon in the coal and coke. Good recoveries of oxalic and aromatic acids can be obtained by direct electrolytic decomposition, in a three-compartment cell, of the potassium salts resulting from the oxidation. Oxalic acid and aromatic acids recovered in this way were 88 and 98 gm. per 100 gm. of coal and coke, respectively. It is pointed out that the failure to recover hydrocarbons more complex than diphenyl by decarboxylation does not necessarily preclude the possibility of the presence of acids with condensed aromatic nuclei containing carboxyl oxygen, since drastic alkaline decomposition is known to split the nuclei of such aromatic acids. R. C. Smith and H. C. Howard (*ibid.*, 234) have also shown that the products of pyrolyzing cellulose at temperatures up to 400° contain benzene and diphenyl.

Refraction and Diffraction of Ultra-Short Waves

IT is probable that in the near future, ultra-short waves (those below ten metres in length) will be extensively used for television, for short-distance point-to-point communications and for communicating from or between aircraft. Any information, therefore, concerning the physical properties of these waves is of great practical importance. In the *Journal of the Institution of Electrical Engineers* of March, T. L. Eckersley, taking up the theory which has been developed by several eminent mathematicians, shows how it can be explained graphically in a method helpful to radio engineers. Hitherto it has been assumed that the earth has infinite resistivity, and formulæ for the propagation of spherical waves round it have been found. Eckersley has extended the solution to the case of a spherical earth of finite resistivity and has deduced results which, at least partially, are borne out by experiment. The problem is not one that can be solved by geometrical optics but requires the full wave theory for its solution. The author considers that diffraction plays the leading part in controlling short wave propagation, but he has found evidence of variation of signal intensity at extreme distances, which he considers can only be caused by the gradient of the refractive index of the air near the surface of the ground. He considers that the hypothesis that the variations are due to reflections from the ionosphere is a very doubtful one. Water vapour has a high refractive index and the effect of a small percentage present is very pronounced. He shows that there is a gain in the signal strength with height in the regions beyond the visible range. Several observers in America using either aeroplanes or autogyros have observed this increase in the signal strength with height, and their measurements are in fair agreement with theory.

The Indian Science Congress Association

HYDERABAD MEETING

THE twenty-fourth annual meeting of the Indian Science Congress Association was held at Hyderabad on January 2–8, under the presidency of Rao Bahadur T. S. Venkatraman, of the Indian Agricultural Service, who was made C.I.E. in the New Year honour list. Summaries of the presidential address and of the addresses of presidents of the ten sections follow.

THE INDIAN VILLAGE

In his general presidential address, Rao Bahadur T. S. Venkatraman discussed "The Indian Village—its Past, Present and Future". The Indian village, which has remained in a quiescent and more or less petrified state for two thousand years, began as a result of Aryan group settlement in the north. This had produced two types of village, the *ryotwari* village, in which a group or family took up as much land as they thought they could cultivate; and the joint village, in which the founders were powerful families, or clans, who were not agriculturists, the cultivators of the soil owing obligation to these families, and being something in the nature of tenants. These villages were self-supporting. and governed by a council of elders, with a system of village industries, of which the practitioners received a portion of the agricultural produce for their service.

The old self-sufficing village system has now broken down by contact with the West, which has brought in competition and the commercialization of crops, now grown not merely for home consumption, but also for export. In the present-day village, notwithstanding the extension of irrigation, seven-eighths of the population are dependent on the monsoon, rendering agricultural income unsteady and uncertain. The village is out of touch with markets, hence a great part of the profit goes to the city which markets the commodities. The increase of population has grown beyond the capacity of the land, especially as the use of manure, animal and human, is banned by sentiment. Sub-division and fragmentation of land militate against efficiency in production and debar the introduction of capital. The attachment to the cow is now working detrimentally, as an enormous head of cattle is carried, which contributes nothing to profits, the only advantage being an abundance of milk. Labour is uneconomical and inefficient, as well as intermittently employed. The villagers are overwhelmed with debt owing to the fluctuation and uncertainty of their incomes, so that many are reduced to the position of serfs. The standard of village life is low, and compares unfavourably in interest with the life of the city. As a result, all the more intelligent are drawn to the towns.

How can the downward tendency be checked? Some provision has already been made by Government organizations for improvement in agriculture and for technical advance. Fragmentation and subdivision need restrictive legislation, education should be extended in village schools with a rural outlook, while intellectual alertness, business habits and a broader outlook on life should be cultivated in the villagers. The co-operative spirit of the villages of old should be fostered anew. Village industries should be encouraged and commercialized, while if products were partly manufactured in the area of production, much of the present cost of transport could be saved. Town and village are complementary, each contributing something to the life of the other. The duty of India is clear, the president said in conclusion, namely "to improve the *Village*, the nucleus of our country life, and infect its Chief Agent the *Villager* with a chosen culture of the virus of modern age through *Education* and *Industrialization*."

ABSORPTION OF LIGHT BY ATOMS AND MOLECULES

Prof. S. Datta chose as the subject of his presidential address to the Section of Mathematics and Physics the "Absorption of Light by Atoms and Molecules", and in the course of it summarized the advances made during recent years, giving references to nearly eighty researches. Under atoms he explained the rule according to which the lines absorbed form only one group of those radiated, and showed that it is not rigidly obeyed. The energy levels of the theory of line spectra must be considered of finite thickness in keeping with the 'uncertainty principle'. The width of the absorption lines is due partly to this and partly to the thermal motion of the atoms of the gas. The intensity is best explained by Dirac's theories, but the thermal broadening and the Raman effect may require a sub-division of the quantum for their explanation. The complex motions which may take place in a molecule, even when only diatomic, account for their more complex spectra; but many of the phenomena of absorption are explained on the theory of both attractive and repulsive forces between the constituent atoms, while the continuous absorption bands may be ascribed to the absence of quantization for the normal vibrations.

CHEMISTRY OF ANTIMALARIALS

In his presidential address to the Section of Chemistry, Prof. J. N. Ray discoursed upon the chemistry of antimalarials, a subject of prime importance to India, since the prevalence of malaria is a most formidable obstacle to progress in that country. It is interesting to note that the cinchona bark, which was first used as a febrifuge in the fifteenth century, still furnishes the best specifics against malaria.

Although quinine has not yet been synthesized, its chemical structure is known, and the physiological action of its various groupings has been closely examined. Thus the superiority of quinine to cinchonine as an antimalarial has been traced to its greater solubility in the red blood cells, on account of the presence of the methoxyl group, which alone differentiates it from cinchonine. Again, while stereoisomerism around the secondary alcohol group, which links the quinoline to the quinuclidine ring, has no marked influence on its pharmacological properties, the latter are destroyed by substitution of hydroxyl by hydrogen, chlorine or acetoxyl. Oxidation of quinine and cinchonine to the corresponding ketones (quininone and cinchonone) is, however, not sufficient to affect their value, since reduction of the keto-group occurs in the body. The chief factor in antimalarial action is probably the quinoline nucleus, but the alcohol group plays an auxiliary part. The vinyl group in the side-chain of the quinuclidine ring does not appear to be directly responsible for prophylactic properties, although hydrogenation increases and oxidation destroys the effect.

Among the numerous synthetic antimalarial drugs are *plasmoquine* and *atebrine*, which are derivatives of 6·methoxyquinoline and 2-chloracridine respectively, each containing the same complex alkylamino-side-chain. Neither plasmoquine nor atebrine, however, has true prophylactic action, for there is no specific action on the sporozites. Plasmoquine is most effective in conjunction with quinine. The combination has been tried on the large scale by the Bengal Government with encouraging results. Robinson and his colleagues have prepared several derivatives, the most promising being 8· (δ·aminobutylamino) 6·methoxyquinoline.

A synthetic drug has still to be found which will have curative value in recurrent infection. The alkaloids of opium appear to be of very little value, but the work of Gunn and Marshall on harmaline, which is effective in acute cases, shows that the search need not be confined to the quinoline series.

Prof. Ray appealed for further financial aid for research in pure chemistry.

INDIAN EARTHQUAKES

Mr. W. D. West discussed "Earthquakes in India" in his presidential address before the Section of Geology and Geography. He traced the beginning of their study to Dr. Thomas Oldham, the first director of the Geological Survey of India, who compiled a valuable catalogue of Indian earthquakes, and investigated the Cachar earthquake of 1869, and the advance to its present state mainly to his son, the late Mr. R. D. Oldham, who wrote the report on the Assam earthquake of 1897, a memoir that has been described as being "worthy of a great subject".

Mr. West divided the country into three great zones, one the belt of Tertiary folding to the south of the Himalayas, the second consisting of the frontal trough of alluvium, and the third the whole of peninsular India. The first zone is that in which all the great earthquakes originate, beginning with the peninsula of Cutch (marked by the earthquake of 1819), and bending round through Baluchistan (the Quetta earthquake of 1935 and others), Northern India (the Kangra earthquake of 1905 and the North Bihar earthquake of 1934), Assam (one of the greatest of all earthquakes, in 1897), and Burma (numerous earthquakes from 1839 onwards). Fault-displacements at the surface occurred with only three of these earthquakes, those of Cutch in 1819, Chaman in 1892, and Assam in 1897.

Mr. West also directed attention to two subjects of great importance, the provision of earthquake-proof buildings in the two northern zones, which coincide with the most populous districts of India, and the foundation of an earthquake research institute for the detailed study of Indian earthquakes.

INDIA'S CLIMAX VEGETATION

Mr. H. G. Champion's address before the Section of Botany directed attention to the neglect of the forest and the tree by the Indian botanical investigator, a neglect that is the more surprising in view of land is under forest, and that the natural climax vegetation for the greater part of the land surface is probably forest.

Mr. Champion pointed out that the direct application of transpiration data from European observations to Indian conditions without verification "is positively dangerous" ; yet the comparison of forests with other types of soil cover and their study in relation to the water economy of the land surface represent problems of great importance to India.

Similarly the lac industry, the supplies of valuable gums, dammars, resins, etc., could benefit by studies of tree physiology, while Mr. Champion's own studies upon the 'spiral grain' of the Chir pine have given an indication of the significance that genetic studies may yet have for Indian forestry.

INDIAN CONTRIBUTIONS TO HELMINTHOLOGY

The presidential address to the Section of Zoology was delivered by Dr. Gobind Singh Thapar. The subject chosen was that of helminthological research in India. Beyond doubt, the subject offers great possibilities in that country, where, apart from valuable work on its medical and to a less extent on its veterinary aspects, comparatively little has been done until recently, when new lines have been opened up and schemes of co-operation set in being. Certain references to helminths in ancient writings, among which possibly *Enterobius vermicularis*, microfilariæ and tapeworms can be recognized, were cited, and the present position of the science outlined. It was pointed out that difficulties arise from the fact that an obsolete terminology is still employed in many general text-books of zoology and there are even errors, sometimes serious ones, in the accounts of the life-histories of common forms.

The helminth fauna of India other than those members of it responsible for human helminthiases is largely unexplored. Details of the morphology of some helminths, *Ascaris*, *Enterobius* and *Labidurus* were given to illustrate how they may play their part in solving problems of classification and relationship. Attention was directed to the discovery of an *Echinococcus* cyst that simulates a *Cœnurus* cyst in that it lacks the typical brood capsules. Brief notice was taken of plant nematodes, host specificity, anthelminthics, pearl formation, etc.

The address concluded with an appeal for a wider appreciation of the importance of helminthological study in India, and for further co-operation among the various workers. Some aspects of this address have been more fully elaborated by the author elsewhere (Lucknow University Studies, 3).

ETHNOLOGY OF THE COORGS

In his presidential address to the Section of Anthropology, Dr. Dewan Bahadur L. K. Ananthakrishna Iyer presented "An Ethnographical Study of the Coorgs". Inscriptions throw little light on the early history of the Coorgs, but from historical evidence it is conjectured that they were not without racial admixture from a remote period. There has been also a great deal of culture contact between the Coorgs and the people of Malabar, Canara and the Tamil districts. Their language is a mixture of Dravidian languages. In physical traits their mountain habitat has differentiated them from the people of the plains. In their economic life they are first

Agriculture, which is of the rudest kind, is similar to that carried on in other parts of India. It has been transmitted unchanged for ages. The industry of the people of the highlands is confined exclusively to the cultivation of rice. Though agricultural implements are few and rude, enough has been produced from ancient times to meet home consumption and to export to Malabar. Where possible the valleys have been formed into flat terraces for cultivation.

The agricultural year opens about the middle of April, when ploughing begins with the first shower. This is a ceremonial observance, in the course of which the ancestors, the river deity and the presiding deity of the division of the district are invoked, and prayers are offered to Siva. Before the completion of the transplanting of the largest field, an open space ten feet wide is left the whole length to provide the race ground for the Coorg sport.

Food supply is plentiful. The Coorgs rear sheep and goats, and the chief article of their diet is rice. Hospitality is proverbial. The houses are situated close to the paddy fields, and resembles the Nayar house. The approaches to the old Coorg house mark the design of fortification, pointing back to the old days of general feuds. Their dress and ornaments are peculiar. Their marriage customs are a medley of old and new. Formerly marriage festivities had a communal character. The Coorg family is joint and patriarchal, and no family affair of any importance may be undertaken without the knowledge of the senior member. The senior female member is the queen of the household. Public morality is controlled by a council of elders. The Coorgs are animists, having ancestor and demon worship ; but they show evidence of the influence of outside beliefs. Of late they have begun to worship the Hindu deities.

AGRICULTURE IN INDIA

For the presidential address to the Section of Agriculture, Rao Bahadur B. Viswa Nath took as his subject, "Science and Practice of Agriculture". Indian soils and agricultural practices, he said, were several centuries old and research should, and was, concerning itself more with details of existing practices than with the evolution of wholly new methods, the aim being to build up on the existing system a state of agriculture suited to the conditions of the soil and the resources of the cultivator.

Work on soil had originally been confined to a study of fertility, but other aspects were now known to be important, and it had been found that characteristics and reactions of different soils were determined by climatic factors rather than by their geological origin. As regards manuring, the importance of organic manures for Indian soils was stressed. Intensive cultivation and continued use of artificial fertilizers were liable to lead to evil consequences if they were not accompanied by the addition of adequate organic matter ; in fact, the utilization of the increased knowledge of the soil obtained by research would be in proportion to the building up of the reserves of organic matter in the soil. Further, the nutritive value of a crop was enhanced by the use of organic manure. With the view of meeting this need, much attention had been paid to the utilization of animal and vegetable waste products. Composting had achieved considerable success, but a simpler and cheaper method was still required if it was to be more generally adopted by Indian agriculturists.

In conclusion, the president showed that there was considerable scope for increased production, as the present yield of food crops was sufficient for the proper feeding of only two-thirds of the Indian population.

ANIMAL NUTRITION AND PUBLIC HEALTH

"The Relation of Animal Nutrition to Public Health in India" was the title of the presidential address to the Section of Medical and Veterinary Research, delivered by Colonel A. Olver. He pointed out the causative role of faulty nutrition in relation to many diseases from which livestock suffer in various countries. Thus, 'bush-sickness' in New Zealand and elsewhere is due to iron deficiency, and calves in India develop a form of blindness caused by vitamin A deficiency in the fodder; well-fed meat and milk of good quality are of higher biological value than similar material of lower quality. In India every year there is a period when natural growth of succulent fodder is almost at a standstill, and when the foodstuffs available for stock are mostly dry, over-ripe crop residues lacking in mineral, vitamin, and other essential constituents. This reacts upon the population, who cannot thrive when the meat is poor and the milk is deficient in quantity and quality.

Colonel Olver therefore urged that more attention and research should be bestowed upon the production of fodder crops of good quality. The production of suitable fodder crops economically in a system of agriculture that is largely governed by the limited capital resources of Indian cultivators is, however, one of the most difficult of the problems with which the better nourishment of the people of India is unfortunately confronted.

INDIAN PHYSIOLOGY

Lieut.-Colonel S. L. Bhatia commented, in his presidential address before the Section of Physiology, on the melancholy fact that in spite of the great importance of a knowledge of physiology among those who are responsible for the well-being of the people, this subject has been little studied in India, in comparison with physics and chemistry. The Section of Physiology of the Association, which celebrates this year its first anniversary, looks forward to a period of vigorous growth, in which professors of physiology now established all over India in full-time chairs with well-equipped laboratories, will direct their energies particularly towards problems of special importance to India—problems of nutrition, of adaptation to tropical climates, and of the application in India of methods which have already been applied in the West.

Colonel Bhatia emphasized the practical importance of physiology by reviewing the growth in Europe of this offspring of medicine, which has had so much influence on its parent, and which has never been so abstract and impractical as some of its critics believe. The decision of the Royal College of Surgeons of England to hold a primary F.R.C.S. examination each year in India will give a great impetus to the study of physiology in all the medical colleges.

The president read quotations from some of the letters of greeting and encouragement which the

Section had received from leading British physiologists. Prof. A. V. Hill spoke of the international character of physiology and of its status as an independent science. If physiology had been content to be merely the handmaid of medicine and to give important positions only to medical men, it would have missed many of its ablest exponents—Pasteur, Langley, Barcroft, Cannon, Bayliss, Lucas, Krogh, Lapicque, and many others, including, we may add, A. V. Hill himself.

SOCIAL MIND OF THE INDIVIDUAL

K. C. Mukherji took, for the subject of his presidential address to the Section of Psychology, the "Social Mind of the Individual". He regretted that there should be any controversy about the importance of social compared with individual psychology, since it is a matter of observation that individual psychology depends as much upon the psychology of society as the psychology of society upon it.

While admitting the importance of the institution of the family life for the welfare of the State in its material aspects, he emphasized that the mental effects of the family life in relation to the foundations of national sentiment are equally important. Although the effects of family life on one hand may be a barrier to the development of wider social interests, it is, however, the necessary preparation for the foundation of the social sentiments. The views of various writers on the ultimate elements of social interests were critically considered.

Mr. Mukherji thinks that life in the first instance is a social life which grows unconsciously, but, when with advancing individual development the critical spirit arises, the unconscious acceptance of the social group becomes modified by conscious effort; thus the social life may be said to be individualized.

The relation of the individual to the group led him to consider the relationship between minor groups under the political, economic, or cultural dominance of a major group. If the minor group accepts the dominance of the major group, there is no trouble; if the minor group assumes an attitude of equality or superiority in some field, it threatens the prestige of the major group, and fear of that loss tempts to aggression. He thinks that this represents the problem of the Jews in Germany, and the Hindu-Muslim tension. The address raised some very interesting problems in a clear form.

X-Ray Studies of Proteins

AT the thirty-seventh lecture of the Bedson Club at Armstrong College, Newcastle-on-Tyne, on March 5, Dr. W. T. Astbury gave an account of his work on the "X-Ray Interpretation of Protein Structure".

Proteins can be divided into two classes, fibrous and globular, and they all contain α-amino acids condensed, primarily, as polypeptide chains. This classical theory of Emil Fischer does not fully characterize the proteins, and research has shown that these long polypeptide chains are folded and further cross-linked by the reactive centres of the side chains. In dealing with the proteins, it is necessary to ask three questions: What are the side chains? How are they distributed? And what is their stereochemical aspect? Dr. Astbury dealt with the last topic.

The fibrous proteins are mainly stable, the simplest being fibroin (silk protein) which consists largely of glycine and alanine residues. Its X-ray photograph agrees with the view of a fully extended polypeptide chain, and this is confirmed by the fact that silk fibres cannot be reversibly stretched. Any stretching that does occur is permanent and due to the crystallites sliding over one another. The stretching of wool, hair, etc., is about a hundred per cent and reversible, and the usual X-ray photograph is not the same as that of fibroin; but on stretching, a similar photograph has been obtained, indicating that keratin (the protein of hair) is a fully extended polypeptide chain system only in the stretched state (β-keratin); the unstretched condition is known as α-keratin. It seems, therefore, that in the β-keratin form the proteins consist of parallel polypeptide chains linked by cross-linkings, while in the normal or α-form these chains are folded. If keratin is stretched and steam applied, the cross-links are hydrolysed and the extension then becomes permanent by the formation of new cross-links. Keratin fibres can also be contracted by nearly fifty per cent (supercontraction) due to further folding of the main-chain. This supercontraction of hair has been found to be very similar to the contraction of muscle. The extension and contraction of many fibrous proteins can take place by free rotation around the single valency links, and therefore unreasonable straining of the valency bonds does not occur.

The globular proteins are only stable within narrow limits. Some of them have been obtained in a crystalline state, and in this condition X-ray investigation has been possible. Svedberg, by means of the ultracentrifuge, has indicated that the molecular weight is a simple multiple of 35,000 (approx.). The characteristics of this class are rapidly lost on denaturation, and the stretched state of the denatured protein gives X-ray photographs very like those of β-keratin and the stretched fibres in general, thus showing that all proteins, whatever they are in the natural state, can be brought to a condition approximating to long polypeptide chains with cross-links.

The folding of these chains must be specific, and Dr. Astbury discussed possible methods by which this could take place, and indicated how supercontraction was brought about. The specificity argues some controlling factor, and it was suggested that this is a property of the side chains.

In conclusion, Dr. Astbury dealt with the feather protein and the virus which causes 'mosaic' disease in tobacco plants. The former falls between the fibrous and globular, while the latter, analogous in several ways to feather protein, appears to be no other than a crystallizable protein bridging the supposed gap between living and non-living matter.

Observations of the Aurora and the Zodiacal Light

IT is one of the attractions of astronomy that useful spheres of work are open to all ranges of instrumental equipment from the largest to the smallest, whilst a few phenomena are best observed initially without a telescope at all. In the category of phenomena for naked-eye study are included the aurora and the zodiacal light, though for critical research these also require the camera, photometer and spectroscope. A memoir issued by the British Astronomical Association (32, Part 3) summarizes the work carried out since 1931 by the section under the directorship of Mr. W. B. Housman, dealing with the aurora and zodiacal light.

The observations were made in Great Britain, in which artificially illuminated skies often present serious difficulty in recording these delicate phenomena, and also in Australia, where for several reasons the conditions tend to perfection for the observation of the zodiacal light. The fascination of watching auroral displays is conveyed by the frontispiece, which reproduces a drawing, made by the late Dr. W. J. S. Lockyer from a ship off the coast of Labrador, of the aurora borealis of August 5, 1932. Owing to their increasing frequency with the rise in solar activity, records of the aurora are of interest to radio research workers and other geophysicists interested in upper air phenomena, as well as to astronomers who look to the sun for clues of their origin.

Observations of the zodiacal light (including the zodiacal band and *Gegenschein*) are being vigorously pursued in a systematic manner. The reality of both short- and long-period variations in the apparent brightness of the zodiacal band is being investigated by a longitudinal chain of workers from Australia to Japan. The observations made by the Section since 1931 (and especially those made by the Rev. R. B. Bousfield, of Queensland) strongly suggest a general variation with that of the 11-year solar cycle. A chart of the zodiacal band, drawn by Mr. H. Jarvis from Bousfield's observations and his own, and first published in *Mon. Not. Roy. Astro. Soc.*, 1934, is reproduced in the memoir; it fills a gap in existing star maps and handbooks.

The Automatic Radio Compass

IN the October number of the quarterly journal entitled *Electrical Communication* published by the International Standard Electric Corporation, there is a paper by H. Busignies describing the automatic radio compass and its applications to aerial navigation.

Ten years ago, attempts were made to develop a compass system, called the 'Hertzian compass', in which the angles indicating the position of a radio transmitter appeared automatically on a graduated scale, similar to the scale of an ordinary magnetic compass. Rough models were made and the essential principles established. Exhaustive trials were made with the collaboration of the French Air Ministry, and commercial production was commenced. It gives an automatic and unbroken visual indication of the direction of a radio station by showing the angle between the direction of this station and the aeroplane's axis. Le Matériel Téléphonique, Paris, constructs a radio compass (R.C. 5 Radio Compass), which indicates the direction of a transmitter on a dial graduated in degrees completely round the circle.

The radio compass may be described as an automatic radio goniometer. It indicates the direction of chosen transmitters which may be situated at any points round the aeroplane. The apparatus is based on the following principle. When a receiving loop aerial turns regularly round a vertical axis, maximum reception occurs every time that the plane of the loop passes in the direction of the transmitter. If the loop turns at a constant speed, a certain number of maxima and minima receptions per second can be observed in a receiver turned on to a transmitter. A rotating speed of five revolutions per second has been chosen as the standard, maxima and minima of receptions taking place at ten per second. The phase of these maxima and minima, that is, the moment at which they occur in connexion with a given origin, depends on the direction of the transmitter in relation to the axis taken as origin. If the location of the transmitter changes in relation to the radio compass, the minima and maxima phases also change, and it is the changing of the phases which is utilized in the apparatus to obtain the automatic indication

A two-phase current generator the phase of which is constant in relation to the revolutions of the rotating loop is placed on its rotating axis. The two-phase current creates a rotating field in a magnetic stator which may be compared to the stator of a synchronous motor. This field rotates at a speed double that of the loop. The variable current from the receiver actuates an armature carrying a pointer associated with a dial. In this armature, therefore, an alternating current is produced by the rotation of the receiving loop, and in the stator a fixed phase rotating field by the two-phase machine. Thus the magnetic reactions of one flux on the other give a definite position to the armature, which sets itself perpendicularly to the flux. The radio compass does not itself indicate the 'sense' of direction, but this 180° ambiguity can be eliminated in several ways. Little if any trouble arises from interference of transmitting stations. The total weight of the apparatus is about 50 lb., depending on the size and type of the aeroplane. The guaranteed accuracy of the apparatus is ±2° for a distance of 300 miles from a 300-watt transmitter.

Guided by the radio compass, the aeroplane always flies in the direction of the station and, if there is no wind, it flies in this direction along a great circle. When there is wind, the pilot determines the drift angle when starting by noticing the course which gives a constant reading of the magnetic compass with a constant indication of the radio compass. Thus, when the correct drift angle has been determined the compass readings can be corrected. In France, both civil and military aviation authorities have submitted the compass to exhaustive trials, and many aeroplanes are already equipped with them.

University Events

ABERDEEN.—At the spring graduation held on March 31, the honorary degree of LL.D. was conferred upon the following, among others: Olaf Bloch, head of the Research Department, Ilford Laboratories; Naughton Dunn, surgeon and lecturer in orthopædic surgery in the University of Birmingham; Prof. A. W. Gibb, emeritus professor of geology in the University; Dr. J. F. Tocher, lecturer in statistics in the University.

CAMBRIDGE.—Dr. F. P. Bowden, fellow of Gonville and Caius College, has been appointed Humphrey Owen Jones lecturer in physical chemistry in succession to Dr. R. G. W. Norrish.

S. D. Elliott has been appointed University demonstrator in the Department of Pathology.

Dr. R. van der R. Woolley has been appointed to the John Couch Adams astronomership and as first assistant observer at the Observatory.

The Amy Mary Preston Read scholarship, value £150, awarded this year for research in scientific subjects, has been gained by J. W. S. Pringle, of King's College, who graduated with a double first in natural sciences in zoology and comparative anatomy in 1934.

GLASGOW.—Dr. George L. Montgomery has been appointed Gardiner lecturer in the pathology of diseases of infancy and childhood.

Sir William Waters Butler has contributed £100 towards the cost of erecting the new Chemistry Institute.

At the Commemoration Ceremony on June 16, the honorary degree of LL.D. will be conferred on: Prof. Jan Boeke, professor of histology and embryology in the University of Utrecht; Sir Robert Muir, emeritus professor of pathology in the University of Glasgow; Prof. Max Planck, emeritus professor of theoretical physics in the University of Berlin; Sir Albert Seward, emeritus professor of botany in the University of Cambridge, recently master of Downing College, Cambridge.

OXFORD.—Sir William Beveridge, director of the London School of Economics and Political Science since 1919, has accepted the invitation to become master of University College in succession to Dr. A. B. Poynton, and will take office on October 1 (see also p. 619).

M. H. Hey, Magdalen College, has been granted the degree of D.Sc. for his work in mineralogy.

The Halley lecture for 1937 will be given on May 28 at 5 p.m. in the University Museum by Dr. B. F. J. Schonland of the University of the Witwatersrand. His subject will be "The Lightning Discharge".

Science News a Century Ago

Brunel on the Thames Tunnel

AT a meeting of the Institution of Civil Engineers on April 11, 1837, Brunel gave an account of the progress being made with the construction of the Thames tunnel, then the greatest work of its kind under construction. The tunnel previously begun by Vazil and Trevithick, he said, had been only about 5 ft. high and 3 ft. wide, whereas the tunnel now being made was 38 ft. wide and 22 ft. high, and it was being excavated by the aid of a shield. This shield consisted of twelve parallel frames ranged side by side, each divided into three cells. Each frame was made so that it either derived support from its neighbour or assisted in supporting those adjacent. The advantage of the system which had been adopted of building by rings had been demonstrated by the fact that the brickwork had sustained two eruptions of the river, but had exhibited no sign of rupture. The great inconvenience suffered was through the want of a drain; an attempt to make one had been made, but after getting into a stratum of quicksand 50 ft. thick, it had to be abandoned. The land springs were a source of annoyance; many of them were extremely offensive, and produced cutaneous eruptions and were an annoyance to the workmen. The difficulties were great, but they would in time be surmounted.

The University of Cambridge and Gresham College

IN 1836 William Palmer (1802–58) was appointed professor of law at Gresham College, London. In his inaugural address he dealt in an interesting manner with the history of the foundation of the College. His address occupied two closely printed columns in *The Times* of April 13, 1837. After referring to the career of Sir Thomas Gresham, Queen Elizabeth's visit to his house in Bishopsgate Street on January 23, 1570, and Gresham's determination to found a college for the several sciences in the City, Palmer quoted from a letter dated March 25, 1575, from the vice-chancellor and senate of the University of Cambridge addressed "To the most accomplished Sir Thomas Gresham, the best maecenas of good learning", urging that the college should be founded at Cambridge and not in London. The letter was in Latin, but the translation ran: "In urging this alone, we would not so strongly or so long contend, unless for the convenient fitness of the place, and for the wholesome state of the air, and usefully for the dignity of the State, and piously for the defence of religion, and fruitfully for the progress of virtue, and happily and fortunately for the advancement of learning and splendidly as well as gloriously for thine own everlasting fame thou mayest erect thy college here rather than in any other place." The college should be at Cambridge or Oxford, but not in London, "to the detriment or almost ruin of either university."

But the compliments of the University could not divert Gresham from his purpose, as seen by his will of July 5, 1575. After his death and that of Lady Gresham, the City and the Mercers Company came into his estates, and the latter applied to Cambridge and Oxford for advice as to the appointments to be made, with the result that of the first seven lecturers three came from Cambridge, three from Oxford and one was appointed on the recommendation of the Queen.

Henderson's Star Observations at the Cape

On April 14, 1837, Thomas Henderson (1798–1844) read a paper to the Royal Astronomical Society entitled "On the Declination of the principal Fixed Stars, deduced from observations made at the Observatory, Cape of Good Hope, in the years 1832 and 1833". Henderson had been appointed to succeed Fallows at the Royal Observatory at the Cape of Good Hope in 1831. He arrived there in April 1832, but had to resign in the following year on account of ill health; and in 1834 was made the first Astronomer Royal for Scotland. In the short time he was at the Cape he did much valuable work under considerable difficulties. In the last of the tables given in his paper in 1837, Henderson included a list of 31 stars, with their direct and reflected zenith distances with the differences he found.

Samuel Hall's Marine Surface Condenser

In the *Nautical Magazine* of 1837, p. 330, it is recorded: "On Saturday, April 15, Mr. Hall's patent improvements on steam-engines, as applied to a pair of 180 horse-power on board the *Hercules* steam-vessel, were investigated by Sir William Symonds and Mr. Ewart, on the part of the Lords Commissioners of the Admiralty. Several scientific gentlemen and others interested in steam navigation were also present. The party proceeded down the river in the *Hercules*, as far as Gravesend, and were well satisfied with the superior working of the engines and the successful competition of the *Hercules* (though laden so as to draw 12 ft. 4 in. water) with other vessels of the finest build, and the best engines, working by injection. The *Hercules* has been running regularly for a year and a quarter between London and Cork; and these improvements besides having stood nearly a three years and a half trial, in a steam packet plying in salt water, the great and important advantages of Mr. Hall's improvements may be considered as established, leaving no doubt that injection engines will hereafter be entirely superseded."

Giovanni Rasori (1766–1837)

Prof. Giovanni Rasori, the founder of the once popular but long extinct doctrine of contra-stimulation, whose death took place on April 15, 1837, was born at Parma on August 20, 1766, the son of a hospital dispenser. After qualifying at Pisa at the early age of nineteen years with a thesis on the more recent ideas in medicine, he spent three years at Florence as assistant to the celebrated surgeon Fontana, and the next two years at Pisa, where he studied under Spallanzani and Peter Franck. In 1795 he travelled to England and visited London, Oxford, Cambridge and Edinburgh, where he made the acquaintance of John Brown, the founder of the Brunonian system.

Rasori's doctrine of contra-stimulation was a modification of the Brunonian system, according to which all remedies except bleeding have a stimulating action and only differ from one another in their degree of stimulation. Unlike Brown, however, he held that in the great majority of cases diseases are caused by excess of stimuli and only a few are due to lack of stimuli. He maintained, therefore, that two kinds of drugs were needed, namely, contra-stimulants, of which tartar emetic was the best example and stimulants, such as ammonia, alcohol and ether.

Societies and Academies

Paris

Academy of Sciences, March 1 (*C.R.*, 204, 625–732).

Alfred Lacroix: A fall of stony meteorite in New Caledonia, on July 16, 1936.

Emile Borel: The approximation of real numbers by rational numbers.

Georges Giraud: Equations and systems of equations in which figure principal values of integrals.

Emile Mathias, Claude Auguste Crommelin and J. J. Meihuizen: The curve of densities and rectilinear diameter of krypton. For temperatures below 190° C. absolute, krypton follows the law of the rectilinear diameter.

Edouard Chatton: A new element of the structure of the Sporozoa: the argyrome.

Antonio Caliohiopulo: The method of selection of the errors of observation.

Ilie Popa: Periodic Laplace series.

Louis Pasqualini: The convexity of a disk of the surface $z=f(x,y)$ projected on the plane $x0y$ along a convex figure K and the second paratingent of which is void, except on a point shaped ensemble.

Jean Delsarte: A generalization of the Euler-MacLaurin formula.

Joseph Fayet: The reduction of homogeneous, linear differential equations to equations with constant coefficients.

Pierre Lelong: The Lindelof principle and the asymptotic values of a meromorph function of finite order.

F. J. Bourrières: The self-maintained oscillations of the extremities of elastic tubes emitting a continuous current of fluid and those of free reeds fitted in at the top.

Jean Capelle: The matching of helicoidal gears.

Pierre Clerget: A machine for classifying combustible liquids according to their advance in inflammation under the conditions of use in compression ignition motors. The results obtained with the machine described show that the relation between the ketene number (Boerlage) and the delay in ignition is not linear, but has a hyperbolic tendency.

Pierre Dive: The variations of the angular velocity in a fluid star.

Jean Dufay, Mlle. Marie Bloch and John Ellsworth: The emission of CO^+ bands in the head of Peltier's comet (1936, *a*). The CO^+ bands were well marked in the spectrum of the head of Peltier's comet, but the spectrum of the tail was too weak to be photographed under the same conditions.

Jules Géhéniau: The moments of impulse in the photon theory of L. de Broglie.

Robert Guillien: The utilization of relaxation oscillations for the measurement of capacities. The method described allows rapid and exact measurements and is specially suitable for the study of the dielectric constants of liquid gases.

Pierre Jacquet: The structure of electrolytic deposits. The experimental results confirm the hypothesis of N. Thon relating to the inhibition of the active centres of a polycrystalline metallic cathode, and show that the discharge of the hydrogen ions plays an essential part in the structure of the metals of the iron group and of all metals obtained in complex baths.

St. Procopiu and G. Vasiliu : Magnetization discontinuities in an alternating field. Explanation of the multiple frequencies appearing in ferro-resonance.

Nicolas Kurti, Paul Lainé, and Franz Simon : Researches on the ferromagnetism of ferric ammonium alum.

Pierre Barchewitz : The position of the CH bands of the halogen derivatives of the saturated hydrocarbons and the electric moment of these molecules.

Jean Terrien : The stimulation by resonance of the fundamental doublet of copper in the vapour of cuprous chloride.

Jean Paul Mathieu : Researches on the Werner complex compounds. The Raman spectra of 4- or 6-co-ordinated compounds.

Maurice Lemoigne, Pierre Monguillon and Robert Desveaux : The characterization and micro-estimation of nitrates.

S. Lj. Yovanovitch : A new electro-analytical method for the determination of antimony.

Henri George and Roger Lambert : The dissociation of zircon. Zircon, fused in an electric furnace and rapidly cooled, is completely dissociated into silica and zirconia (ZrO_2).

Armand Marie de Ficquelmont : The constitution of mineral rubber. Studies on the phosphonitrile chlorides, $(PNCl_2)x$.

Mlle. Yvonne Garreau : The preparation and constitution of cyclohexylammonium 2,5-dicyclohexylamino-1,4-quinone-3,6-disulphonate, of 2,5-dicyclohexylamino-1,4-quinone and of hydroquinone-2,5-disulphonic acid.

André Cornillot : A mode of representation of organic compounds.

Marcel Tuot : The formation of nitrosochlorides starting with C_6 to C_{11} ethylenic hydrocarbons.

Charles Prévost and Joseph Wiemann : The iodizing properties of the iodo-argento-benzoic complex compound.

Stanislas Goldsztaub : The crystalline structure of laurionite.

André Rivière : The granulometric constitution of the sandy sediments and the broad lines of their evolution in different geological media.

L. Clariond and Mlle. Yvonne Gubler : The presence of Acadian and post-Acadian eruptive rocks to the south of Djebel Ougnat (South Morocco).

Lévi Herman and Mlle. Fanny Bernstein : The relations between the variations of the intensity of the ultra-violet solar radiation, measured at the level of the soil, and the pollution of the lower atmosphere.

Josef Szuleta : The tannin cells in the pith of the elder (*Sambucus nigra*).

André Sarazin : The evolution of the chondriome and of the vacuolar system in the carpophores and especially in the basidia of *Agaricus campestris*.

Mme. Jeanne Werner and Roger Guy Werner : The study of some lichen gonidia isolated in a pure culture.

Pierre Lepesme : The external action of arsenical preparations on insects.

Gabriel Guignon : The post-nymphal development of the wings of the Lepidoptera.

René Salgues : The preventive fungicidal properties of methylene blue in animal pathology.

Antoine Magnan and Henry Girerd : Attempts at the cinematography of the wings of birds in motion in three mutually perpendicular directions.

Wladislas Kopaczewski and René Paille : Gel formation of whole blood.

Mme. Raymonde Duval : The action of the electric current on hæmoglobin in the presence of different electrolytes.

Alexandre Besredka and Ludwik Gross : Intracutaneous immunization against epithelioma and its mechanism.

Washington, D.C.

National Academy of Sciences (*Proc.*, 23, 1–39, January 15).

S. Atwood : The last premeiotic mitosis and its relation to meiosis in *Gaillardia*.

A. C. Kinsey : An evolutionary analysis of insular and continental species. Nearly 400 species of the family Cynipidæ (gall wasps) have been studied in the United States, Mexico and Guatemala. These wasps provided good material for the study of insular species because each is restricted to a single kind of oak or group of related oaks, and further, the oak hosts in the western area are limited to high mountain elevations. Some 76 per cent of the wasps are classified as insular species. They are usually homogeneous in constitution, and show few local populations and few inter-specific hybrids ; mutation and early isolation of new types are the important factors in increasing the number of such insular species.

G. Birkhoff : Integration of operators.

G. A. Miller : Groups which contain an Abelian subgroup of prime index.

J. v. Neumann : Algebraic theory of continuous geometrics.

W. J. Crozier and A. H. Holway : On the law for minimal discrimination of intensities (1). As a result of a discussion of visual, auditory and other data, it is concluded that the properties of a marginal discriminable interval of intensity are determined by probability considerations, and are completely independent of specific structural and other properties of the receptor field. It is important to use homogeneous data.

Morgan Upton and A. H. Holway : The psychophysics of hearing. (1) Monaural differential sensitivity and exposure-time. A relationship has been determined between the just noticeable increment in intensity and the exposure time, utilizing one ear and continuous increase of intensity, at three levels of intensity. (2) Binaural differential sensitivity and exposure-time. The same relationship found for one ear applies when two are used, but the just noticeable increments of intensity are lower at each level for binaural hearing.

E. Witschi : Stimulative and inhibitive induction in the development of primary and secondary sex characters. Work with salamanders united experimentally with a strand of tissue containing blood vessels, gives evidence of the production by the medulla of the gonad of two inductive substances. One stimulates testicular differentiation, but within the gonad only ; the other inhibits ovarian differentiation of the cortex and is carried in the blood like a typical hormone. These substances are not the same as the testicular hormone, which stimulates merely the last functional development of the male secondary sex characters.

Forthcoming Events

Monday, April 12

Royal Geographical Society, at 5.—Prof. E. G. R. Taylor: "The Geographical Ideas of Robert Hooke".

Tuesday, April 13

Illuminating Engineering Society, at 7.30.—G. T. Winch and L. Jesty: "Television Images: an Analysis of their Essential Qualities".

Thursday, April 15

Institution of Civil Engineers, at 6.—J. L. Savage: "The Boulder Dam".

Chemical Society and Society of Chemical Industry, at 8.—Joint Discussion on "Physico-Chemical Problems involved in Distillation" to be opened by Prof. J. Reilly.

Friday, April 16

Institution of Electrical Engineers (Meter and Instrument Section), at 7.—J. B. Kramer: "The Photocell and its Applications in Industry".

Royal Institution, at 9.—T. Macara: "Science and the Conservation of Food. Some Special Problems".

British Psychological Society, April 16–20.—Extended General Meeting to be held at the University of Manchester.

Appointments Vacant

Applications are invited for the following appointments, on or before the dates mentioned:

Junior Assistant Mycologist in the Midland Agricultural College, Sutton Bonington, Loughborough—The Principal (April 12).

Assistant Engineer in the Mechanical and Vehicle Engineering Section of the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, London, S.W.1 (April 12).

Chemical Engineer at the Royal Gunpowder Factory, Waltham Abbey—The Principal Clerk (April 14).

Junior Scientific Officer at the Fuel Research Station, East Greenwich—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W.1 (April 20).

Serologist in the Ministry of Health—The Director of Establishments, Ministry of Health, Whitehall, S.W.1 (April 24)

Lecturer in Chemistry in the Natal University College, Pietermaritzburg—The Registrar (May 31)

Inspector of Aviation Fuels and Lubricants in the Aeronautical Inspection Directorate—Secretary, Air Ministry (S.2.d.), Adastral House, Kingsway, W.C.2

Secretary of the Institution of Gas Engineers, 1 Grosvenor Place, S.W.1—The Secretary.

Physical Training and National Well-being

THERE are undoubtedly some who will see a connexion between the Government's campaign for improving the health of the people of Great Britain by physical education and the difficulty experienced by the War Office in obtaining recruits of a sufficient standard of physique for the army. Although, perhaps, the Government proposals have been a little over-advertised, a balanced and scientific attempt to improve the physique and health of the nation is so long overdue that we need not mind from what quarter the final stimulus is supplied.

It should not be overlooked that recent reports of the Commissioners for the Special Areas have insisted upon the need for physical training and recreation, while at the same time they have stressed the need for simultaneous attention to nutrition. In the memorandum which has been issued explaining the Government's proposals for the development and extension of the facilities available for physical training and recreation, it is admitted that bodily fitness depends on two essential elements, nutrition and physical training. Action has already been taken in many ways with regard to the former, and the present proposals are accordingly limited to the latter problem.

The proposals outlined in the memorandum include the establishment of two National Advisory Councils, one for England and Wales, and one for Scotland, to survey the field and to advise as to the best methods of meeting the needs and the lines of general advance. The personnel of these Councils has already been announced and includes representatives of many associations of physical culture of one sort or another, such as Scouts and Guides, the Young Men's and Young Women's Christian Associations, boys' clubs, girls' clubs, the League of Health and Beauty, the English Folk Dance and Song Society, the Margaret Morris movement, etc. Two grants committees are to be established through which, subject to the approval of the responsible Minister, grants will be payable. The National Advisory Councils will organize local committees to develop and co-ordinate the work in various localities and to advise the grants committee on the distribution of local grants. A National College of Physical Training is to be established, and in addition to a grant to the National Playing Fields Association, an interim grant to the Central Council of Recreative Physical Training is proposed. Legislation will be introduced to enable the grants committee to make grants to voluntary bodies and to local authorities, and to empower local authorities to provide community centres, to remove limitations on their present powers of providing physical and social facilities, and to empower county councils to contribute towards the cost of county district councils in the exercise of their powers under the Bill and their power of providing swimming baths.

It is beyond question that the existing provision of facilities for physical training and recreation in Great Britain is both insufficient in amount and sporadic in incidence, being sometimes lacking where most required, and, hampered by want of funds for development, is unable to do more than touch the fringe of the problem. Indeed, the main criticism of the scheme so far advanced is that certain classes of the community are too inadequately nourished to participate in physical training or recreation without risk of further physical deterioration.

To this objection, it is no complete answer that the problem of nutrition is being handled elsewhere. The question of the physical condition of the people must be studied and handled as a whole on scientific lines, and all the relevant factors must be taken into simultaneous account. In the Special Areas, and probably in certain other districts or sections of the community, the development of physical training facilities can do no more than follow the improvement of nutrition and general health, or at the best proceed with it and the need for a constructive and well thought out policy in national health can scarcely be better illustrated than in passages of the Commissioner's recent report.

It would be a tragedy, however, if criticism of this type, or the attention which has since been given to the White Paper on Rearmament, led the nation to lose sight of the ideals and the political philosophy which inspire the present proposals. They will fail of their purpose unless the fullest use is made of them by the existing agencies, whether voluntary bodies or local authorities. Their essential task is not merely to provide facilities sufficiently attractive to make an effective appeal to the people of the country. It is primarily to create in the public mind a realization of the value of physical fitness for its own sake.

This, even more than the fact that the scheme is an attempt to extend to all classes certain physical advantages that are now enjoyed only by the more favoured classes, is the most significant aspect of the Government scheme. Although the country is comparatively well off for voluntary institutions to improve the physique of the mass of the people, the State has done nothing beyond the school age. The recognition that the duty of the State extends beyond the school in this field is not merely an advance in democracy: it is essentially an attempt to achieve a better adaptation of the citizen to his environment in a society dominated by power production.

The new conception of public health which we encounter here is not that inspired by the totalitarian States, even if they have been responsible for some of the first, though perverted, experiments in this field. Its force derives primarily from the necessity of the State intervening to afford the citizen fuller opportunity of physical and mental development in an era when economic forces inherent in an age of power production have severely circumscribed such opportunities and enhanced their importance.

The need for biological adaptation in industrial civilization has so far largely been overlooked, despite a brilliant chapter on this theme by Lewis Mumford in "Technics and Civilisation". None the less, the attempt must be made if man is to regain the mastery of the machine and reap the advantages in the way of an ampler life which that mastery would offer to all. The retreat to the primitive inherent in certain modern dictatorships makes the problem the more urgent. Civilization cannot be run by barbarians, and the refusal of the totalitarian State to face the basic and difficult problems involved in the transition from the historic forms of capitalism and the limited original forms of the machine to an economy centred on life is the more serious through the threat it offers to human motive power, its discouragement of co-operative and creative thought and the disinterested research on which technical achievement as well as spiritual progress rest.
